STATEMENTS OF [illegible] AND [illegible] RAL MANAGEMENT AND PRODUCT, IN [illegible].

[[illegible] figures [illegible] merely from the [illegible] that the wri- [illegible] in a high degree, the [illegible] which are necessary to constitute a good farmer. We had heard, long ago, that Commodore Jones had rendered valuable services to his country, by improving her soil, as well as by defending it in battle. It is hoped that this first communication to the Farmers' Register from his pen, is the precursor of others; and the evidence here exhibited of value, both in working and in writing on so small a space, shows that our correspondent cannot want either a field, or fit subjects, for more extended treatment.—Ed. Far. Reg.]

To the Editor of the Farmers' Register.

Prospect Hill, Va., February 16th, 1838.

Dear Sir:—Forced to take shelter in the house from the pelting storm now raging, and of course to suspend all out-door farming operations, I turned to my agricultural library, to seek in theory that which I may apply to practice, when the season for operation arrives. The January and February numbers of the Farmers' Register having just come to hand, I turned to the index, which directed me to your appeal to 'subscribers in arrear' at page 690, and after reading that article, I referred to the receipt of your collecting agent, who called on me in April last, and find that I did not then, as I had supposed, pay for the present vol. (the 5th) of the Register; consequently, I am not only indebted to you for the 5th vol., but soon shall be for the forthcoming, or sixth; to discharge which, in compliance with your terms, I send you a check on the Bank of the Metropolis at Washington, whose notes are current, I believe, all over Virginia, for ten dollars, which will square our *cash account* for a year to come. But how I, and the community at large, will ever pay the debt of gratitude we owe to the author of the 'Essay on Calcareous Manures,' and his efforts in the cause of agriculture, as displayed in the Farmers' Register, it is not easy for me to say. I feel my own indebtedness, and know not how to cancel it; for although a practical farmer for fifteen or sixteen years; although I have made "two ears of corn, and two blades of grass, to grow upon a spot of ground where only one grew before," still, from being of another profession, nothing that I could write or say would be deemed orthodox, by that class of Virginia farmers who stand most in need of new light in *practical farming*.

The subjoined statement of the treatment or management and product of a small piece of ground, being a fraction less than an acre, may be interesting to you at least; and I have now under somewhat similar treatment a good many more acres, no less productive, according to the advance in improvement. The acre here described, when taken in hand, had not for many years produced one barrel of corn. It is on the side of a hill, sloping to the north-west, and like most of the land adjoining me, is argillaceous; and, when ploughed deep, is retentive of moisture, but not subjecting grain to winter-killing, as many clay soils do. The surrounding country is undulating, hilly, and in some places broken; the original growth is red oak and hickory, with large white oak, yellow poplar, and some locust and walnut interspersed. When first cleared, it is fine tobacco land, and will produce five or six barrels of corn, and 12 or 15 bushels of wheat per acre for a few years, without manure, (which, until very recently, was not thought worthy of the attention of those who called themselves farmers.) But, as already observed, the land being hilly, generally ploughed shallow, *and without the least regard to the destructive consequences of washing*, the country around me presents, with some exceptions, a scene of barren hills and gullied valleys. But even these gullied hills, with good ploughing, or a single dressing of manure, become rich in the product of *grass* or *grain*, and are as easily kept so by the use of *lime*, plaster and clover, as any other lands in Virginia, *or elsewhere*, which are not alluvion, or which do not contain lime as a natural constituent.

To return then to the subject. My land was deeply ploughed, say 7 inches, in early spring of 1831. In May, sixty-two mule-cart loads of stable manure was carted on, regularly spread, and ploughed down, say 4 inches deep, and rolled with a heavy roller; in three weeks, it was cross-ploughed to the same depth, and so remained until the latter part, *say the 23d of July*, when it was again ploughed with the double-shovel plough, again rolled, and sown immediately with white Dutch and winter red top turnip seed of equal parts, and harrowed in with an iron-tooth two-horse seed-harrow. For products, and six years subsequent treatment, see the following table.

Memorandum of the culture and products of an acre of land in the County of Fairfax, for seven consecutive years.

In 1831. Produced 600 bushels of turnips, at 25 cents per bushel,	$150 00
" 1832. Oats, 72¾ bushels, sold at 45 " cents per bushel,	32 72
Stubble turned in and sowed with wheat and clover-seed in September.	
" 1833. Wheat, (lodged and did not fill well,) only 19 bushels, sold at $1 25 per bushel. Mowed the stubble in October, and got one and a half tons of cow food, worth $12,	35 75
" 1834. Clover; June cutting 3 tons, $36; September, 1½ tons, at $12,	48 00
Fallowed after 2d mowing and sowed with wheat, harrowing in *fifty bushels of quick-lime* at the same time.	
" 1835. Another bad wheat year, (blos- " som washed off by hard rains,) only " 22 bushels at $1 25. Mowed the " stubble in September, one and a half	

" tons of mixed hay, worth $12,	39 50
" 1836. Clover and herds' grass, 3½ tons	
" $15 per ton,	52 50
2d crop ploughed under, preparatory for corn.	
" 1837. Planted latter part of April with *Baden's twin corn*, 4 feet 2 inches each way; put a good handful of ashes, lime, and plaster of Paris combined, in each hill; product over ten barrels; say 10 at $3 50 per barrel,	35 00
	$394 27

The above land received from two to three bushels of gypsum, annually put on at various periods, but *never failing to follow the scythe with a good dressing of plaster.* Ground plaster costs from $7 to $9 per ton in Georgetown. Fresh lime, at kilns in Georgetown, in 1834, cost 15 cents per bushel; now, 12½ by the quantity. From these data, let the skeptic make any deductions he may think proper for expense of cultivation, at the highest wages for man and beast, and add interest on all cost and charges, and still there must remain a clear profit but little short of $50 per annum, from rather less than one acre of ground, which, previous to manuring in 1831, was utterly worthless, but is now considered rich. It has on it 30 flourishing young apple trees just getting into bearing, and promises a good crop of wheat seeded the last of October.

N. B. The labor I employ is slave labor. The putrescent manures are of course produced on the premises; and, with the exception of wheat and turnips, the above prices are commanded for drovers, and a relay of stage and other travelling horses which traverse the turnpike, and I get the manure gratis, besides a good rent for an* establishment which cost me about $800.

My location is just eight miles from Georgetown market-house; of course, I have a choice of the three markets of the District of Columbia, to sell or buy at, where every article which the *earth produces*, which enters into the use of man, commands, at all times, ready sale. Yet, I must tell you, that lands almost adjoining me, which pay a good *interest* on their estimated value, by sale of *wild berries*, &c. from the uncultivated fields, or from the product of dairies, where the cows depend upon the *woods* and the *commons* for a support three-fourths of the year, are rapidly depopulating, and running into barren waste, by reason of the mania, I must call it, which impels so many persons to abandon the homes of their fathers, and the enjoyment of health, comparative ease, and comfort, to seek their fortunes in the bogs and cane-brakes of the south and south-west.

When I sat down to write, I had not the least intention of thus persecuting you with a lengthy epistle, but the spirit seemed to move me, and I thought it best to give it vent; and if you cannot decypher this scrawl, you will not lose much by it, but perhaps save me some mortification hereafter.

With grateful return for what you have done, and are still doing, for the agricultural interest of the dear "old dominion," I subscribe myself your friend and servant,

THOS. AP. C. JONES.

*Illegible.---ED.

P. S. Can you not persuade Professor Rogers to take a look at this out-of-the-way corner of the state? We have many sorts of *stones* about here, (between the great and little falls of the Potomac,) and some say gold, some say lead, some coal, some copper, some have found limestone, &c. &c. &c.: but I say we abound in worn-out lands and bad farmers, who require the word of such a man as the professor, to make them set a proper value on their possessions, and the means within their reach of improving their lands.

T. A. C. J.

LIMING ON THE EASTERN SHORE OF MARYLAND.

To the Editor of the Farmers' Register.

Chestertown, Md., Feb. 17th, 1838.

* * * * *

It gives me great pleasure to have it in my power to say, that there is a great spirit of improvement amongst the farmers with us. In many places, you will see fine fields of clover, where, a few years ago, nothing but poverty grass was to be seen; and in almost every direction, now, the farmers appear to be turning their attention to the improvement of their land; and if they will only continue it, there is not much doubt but that they will be richly compensated for their trouble; for our lands are very susceptible of improvement, and with proper management, may be made to produce with any lands in the state. Within a few days past, there has been an agricultural society formed here; and if it can be conducted in the manner that we now have it in contemplation, I have no doubt but that it will be productive of much good to the farming interest.

I received a circular from you some time ago, but as it has only been within the last year or two past, that any shell marl, or green sand, has been carried out on our lands, I have been unable to get hold of any information which would enable me to give you any satisfactory answer to the queries it contained. As soon as there has been sufficient time to test the value of them, I will let you hear from me.

For several years past, many of the farmers of this county have been using the shell lime with great success. It has been used in various quantities, from 100 to upwards of 200 bushels per acre. The quantity depends upon the condition that the land was in. Where it was thin, it has been deemed advisable to give it a light dressing at first. There is a great difference of opinion with regard to the manner in which lime should be applied; some contending that it is better to spread it in the fall, on the land that is to go in corn the following spring; others, that it is better to apply it in the spring, after the ground had been broken up. For many years past, I have been using the shell lime with great effect, and have generally applied it in the spring, after the ground has been ploughed and the corn planted. I have been in the habit of carrying out, in the spring, the manure that was made in the farm-yard through the winter, and after having it put in the furrow, and the ground listed and ploughed out, I have had a shovel full of lime spread over the ridge from corn-hill to corn-hill; and if the season was tolerably good, have hardly ever failed to make a good crop of both wheat and corn, from land that was very thin before the application of the lime and manure. A part of the field that I had in cultivation on my farm in this county, in the year 1835, was land that, on account of its barrenness, had not been in cultivation for 8 or 10 years before, and when it was ploughed, it was covered with poverty grass. This piece of land, I treated in the following manner, viz.: In the spring, I had the manure, that was made in the farm-yard through the winter, carried out on it, and after having it put in the furrow, and the ground listed and ploughed out, (which was done as soon as the manure was spread,) and the corn had been planted, I had a shovel full of lime spread on the ridge from corn-hill to corn-hill. Shortly after, I used the large drag harrow, which appeared to mix the lime pretty well with the earth. In consequence of the heavy rains that we had in the months of May and June, and it being rather low stiff land, I was unable to give the corn the usual cultivation, and made little or none from it. In the fall of the year, it was seeded in wheat, and the spring following, clover was seeded on it. This piece of ground yielded me from 18 to 10 bushels of wheat to the acre, each bushel weighing 60 lbs.; and when the wheat was cut, the clover, that had been seeded in the spring, was about a foot high, as thick as I could have desired it, and the greater part in blossom. This fine growth of wheat and clover, I attribute in a great measure to the lime, for I have frequently tried the same kind of manure without the lime, and have never discovered much benefit from it. On my farm in Queen Ann's county, which is rather a light soil, I have been using the shell lime ever since the year 1822, and have generally applied it in the spring, after the ground has been ploughed, and it has always acted very finely. In the year 1828, I limed a piece of land, in one of the fields on this farm, which was covered with sorrel and poverty-grass. It did not appear to have any effect upon the corn crop, but the effect was very visible upon the wheat, which followed the corn; and after the wheat was taken off a fine growth of white clover come up in the place of the poverty-grass and sorrel, and ever since it has been producing fine crops, without the aid of any other manure. I am decidedly of the opinion, that it is better to apply the lime after the ground is broken up; for in this way, you keep it near the surface, and it also becomes more immediately and better incorporated with the earth; both of which, I think, are very desirable. The farmers are becoming sensible of the great importance of lime, and are very generally getting into the use of it.

GEO. S. HOLLYDAY.

From the Medico-Chirurgical Review.

THE RAIL ROAD STEAMER.

By James Johnston, M. D.

Were any of the ancients to rise from their tombs, and to behold a steam-ship, full of passengers, darting up the Thames, or a train of carriages, with a thousand people, flying along a rail road at the rate of 30 miles an hour, they would be very apt to doubt the fact of their revisit to the same planet they had left—since a thousand years in the grave may probably seem no longer than a short siesta after dinner. Their surprise would not be much lessened by the sight of a column of brilliant flame springing up from the middle of a street, or issuing from ten thousand metallic tubes, and turning the darkness of night into the glare of day! If, while gazing at these phenomena, they saw a man, or even a monkey, descend from the clouds, suspended as the pendulum of a huge umbrella, they would no longer doubt that they had got into "another, if not a better world," than that of their birth and death!

But to return to the *rail road steamer*. Without rudder or rein; without tug or tow-rope; without chart or compass; without impulse from *man*, or traction from *beast*—this maximum of power in minimum of space—this magic *automaton*, darts forward, on iron pinion, like an arrow from a bow, along its destined course. Devised by science, but devoted to industry; harmless as the dove, if unopposed; but fatal as the thunderbolt, if obstructed in its career; this astonishing offspring of human invention; this giant in strength, though a dwarf in stature, drags along, and apparently without effort, whole cargoes of commerce; merchants and their merchandize, artizans and their arts, travellers and their traffic, tourists and their tours (some of them *heavy* enough)—in short, every thing that can be chained to the tail of this herculean velocipede!

The steam-carriage nearly annihilates distance between the inhabitants of a state, and thereby converts, as it were, a whole country into a city, securing all the good effects of combination and concentration, without the detrimental consequences of a crowded population. By the rail road, Liverpool, Manchester, Birmingham, and the Metropolis, are constituted *contiguous* cities, while wide and fertile tracts of country intervene! Thus *steam* multiplies the products of human labor, by increasing their sale and diminishing their price. It will enable us to convert millions of acres from pasturage into cornfields, and consequently the provender of horses into food for man.

The whole transit of a *rail road steamer* is a series of miracles, which, in former days, would have been attributed to angels or demons. At starting, the mighty automaton suddenly suppresses his torrent of hissing steam, and belches forth a deep and hollow cough, which is reiterated at shorter and shorter periods, like a huge animal panting for breath, as the engine, with its train, labors up the ascent from Euston square. These belchings more nearly resemble the pantings of a lion or tiger than any other sound that I know of. With the slow motion, on any considerable ascent, the breathing of the animated machine appears to become more laborious, and the explosions more distinct, till at length the animal seems exhausted, and groans, as it were, under the tremendous effort. But the engine, having mastered the difficulty, acquires velocity before it plunges into the dark abyss of the tunnel under Primrose-hill. There the peal of thunder; the sudden immersion in cimmerian darkness; the clash of reverberated sounds in confined space; the atmospheric chill that rushes over the frame; all combine to induce a momentary shudder at the thought of some possible collison or catastrophe in this subterranean transit, which is increased rather than diminished y the gleams of dubious light that occasionally break in from above, or the sparks of fire that issue every instant from the chimney, rendering "darkness visible." On emerging from the gloomy and gelid cavern, every thing appears of dazzling brightness, and we breathe with delight the pure atmosphere of heaven.

The moment the highest point of elevation on any part of the road is gained, and a descent commences, the engine, with its long train, starts off with augmenting velocity, dashing along, like lightning, and with an uniform growl, or roar, like a continuous discharge of distant artillery or thunder. The scene is now grand—I had almost said terrific. Although it may be a complete calm, the wind appears like a hurricane; and, while the train is flying along the raised embankments, as near Watford, it is impossible not to feel some sense of danger, or an apprehension that some unexpected impediment may hurl the whole cavalcade into the yawning gulf below!

The meetings of the trains flying in opposite directions [on double tracks] are scarcely less agitating to the nerves than the transits through the tunnels. The velocity of their course—the propinquity, or apparent identity of the iron trajets along which these hissing meteors move, raise the involuntary but frightful thought of a possible collision, with all its horrible consequences! The period of suspense, however, is but momentary. An electrifying concussion, as it were, of sense, sight, and sound takes place, and, in a few seconds, the object of terror is out of view behind.

But such herculean labor cannot be carried on in so small a compass, without great expenditure. The *automaton* thirsts; he knows the places of refreshment; utters a loud and piercing whistle or note of preparation; slackens his pace; halts at the fountain, and ingurgiates a deluge of water to quench his burning drought. In five minutes he is able to renew his gigantic task!

The steam shriek is a new phenomenon on the rail road, and a very startling one it is. By opening a small valve in the boiler, a volume of steam is driven, with tremendous force and velocity, through a narrow aperture, in imitation of a throat, causing a shrill shriek, unlike the voice of man, or of any known animal, but so loud as to be heard two miles off. It is a most unearthly yell, or scream, or whistle: which was compared by a distinguished poet, who sat beside me,* to the cry of some monstrous animal while being gored to death. It forms an excellent alarum, to clear the road for the train, and apprise those at the stations, that the engine approaches.

The rail road travelling possesses many peculiarities, as well as advantages, over the common modes of conveyance. The velocity with which the train moves through the air is very refreshing, even in the hottest weather, where the run is for some miles. The vibratory, or rather oscillatory motion communicated to the human frame, is very different from the swinging and jolting motions of the stage coach, and is productive of more salutary effects. It equalizes the circulation, promotes digestion, tranquilizes the nerves (after the open country is gained,) and often causes sound sleep during the succeeding night, the exercise of this kind of travelling being unaccompanied by that lassitude, aching, and fatigue which, in weakly constitutions, prevents the nightly repose. The rail road bids fair to be a powerful remedial agent in many ailments to which the metropolitan and civic inhabitants are subject.

To those who are curious, and not very timid, the open carriages are far preferable to the closed ones, especially in fine weather. In bad weather, and particularly at first, invalids may travel with more advantage under cover. I have no doubt that to thousands and tens of thousands of valetudinarians in this overgrown Babylon, the run to Boxmoor, or Tring and back, twice or thrice a week, will prove a means of preserving health and prolonging life, more powerful than all the drugs in Apothecaries' Hall.

In fine, a man may travel from the pole to the equator—

"A Gadibus usque ad Gangem"—

without seeing any thing half so astonishing as the wonders of the rail road. The pangs of Etna, and the convulsions of the elements excite feelings of horror and terror, without any thing of pride. The magic—the miracles of the rail road, engender an exulting consciousness of superiority in the genius of man, more intense and conclusive than any effort of poet, painter, or philosopher.

The rail road journey, however, is not without its inconveniences, many of which may be prevented by a little ingenuity. The greatest is the discharge of cinders, some of them ignited, from the chimney, which are not only disagreeable, but occasionally dangerous to the eyes of those in the open carriages. This might be prevented by an awning—a protection which is adopted on some rail roads, and one that must ultimately be adopted on all. It is a protection from the elements of fire and water, which every company is bound to afford to the passengers, and is attended with trifling expense. Till then, glasses or a veil are necessary guards for the eyes.

The transits of the tunnels, in hot weather, causing a sudden vicissitude of temperature, to the extent of 20 degrees of the thermometer, or thereabouts, require some precaution on the part of sensitive invalids. A shawl or large handkerchief, thrown over the head, is a sufficient protection, and those who do not take this measure, should keep their eyes shut, during the passage, since sparks and cinders are, unavoidably, thrown in closer showers over the passengers here than in the open space.

To speculate on the normal, physical, political, and economical effects and consequences of rail roads and steam navigation, when carried to their full extent, is beyond my province—perhaps beyond the bounds of human foresight. If the semi-civilized peasants of the remotest isles of the Hebrides, of Orkney, and of Shetland, can even now, transmit, in a few hours, the produce of their huts, their mountains, their moors, and their farm-yards, to the markets of Glasgow and Edinburgh, so as, in three or four days, to pay the annual rents of their tenements and wildernesses, what may we not expect from the extension and perfection of this facility of intercommunication? In days of yore, the imponderable products of the intellect travelled as slowly as the material merchandize of mankind. They will now be diffused, from the centre to the periphery—from the remo-

* Campbell.

est outlines to the loci of society, with a rapidity little less than that of *thought* itself! ! The ultimate *consequences* cannot be appreciated at present: but we may safely conclude that the benevolent author of our existence did not endow the mind of *man* with such extraordinary powers of invention, without the *design* of final advantage to his physical wants, his social relations, and his spiritual nature.

THE TRADE FROM THE WEST, BY THE JAMES RIVER AND KANAWHA IMPROVEMENT.

Extract from the Report of the Chief Engineer, Charles Ellett esq., to the late General Meeting of the Company.

It is not my intention to indulge at this time in any general reflections on the probable result and prospective advantages of the improvement. Indeed it would be as unnecessary as it would be difficult, to attempt an examination of all the influences which a work of this nature exercises over the prosperity of a state. It would be to trace the consequences of a general diffusion of wealth and commercial prosperity through every department of business and every branch of trade. If we were anxious, we might arrive at a more accurate and useful result, by considering the present consequences of a stoppage of some great work in active operation—as, for instance, the Erie canal of New York; by reflecting on the consequences to the emporium of that state, and to her agricultural, manufacturing and mercantile interests, of cutting off the eight hundred thousands tons of produce and merchandise that annually pass through it; of destroying the improvement that created the line of towns and cities from Buffalo to Albany, and that forces every cultivated acre north of the Ohio and east of the Mississippi to contribute to the growth of her wealth and power.

During the last year a breach occurred on the long level of that work, and the New York papers informed us that before it was repaired *seven miles of canal boats* collected near the adjacent locks. And now to stop the Erie canal would be more withering to her prosperity than to close up the "Narrows" which admits her foreign commerce, and more fatal to her advancement than any misfortune she could experience, excepting the loss of the energy and enterprise of her population.

I am sensible that there are those who are sufficiently aware of the importance of that work to the state by which it was made, and who can appreciate the consequences of its destruction, but who are disposed to doubt whether the James river improvement can be regarded as an analogous project. These will admit, what is undeniable—that a considerable portion of the country traversed by the latter work is quite as fertile as that which contributes to the trade of the former, and that its mineral wealth is incomparably greater; but, by over-estimating the influence of the lake trade on the tolls of that improvement, are brought to a false comparison.

Notwithstanding the rapid and unparalleled progress of internal improvements in this country, our minds are still embarrassed by the mode of considering the subject applicable to prominent European examples. Works having there been long in successful operation, furnished us with the facts which were originally employed by the advocates of similar enterprises in this country; and it is not easy to change a habit of thinking which has been long established, and to which the mind has become attached by the indulgence.

But when we estimate the probable consequences, and value of an improvement adapted to the peculiar condition and grand divisions of this country, we must view the subject in an aspect different from that of a work connecting two lakes or towns, where the trade already is, and where the consequences of their connexion may be determined from existing facts. Here things are different; the improvement creates the trade, and the trade which it creates supports the work that brought it into existence. The value of a work here depends on the place *to* which it reaches but in a secondary degree; the primary considerations being, nearly always, the character of the soil *through* which it passes, and the length of the line of the improvement.

The Erie canal is not supported by the trade of the lakes; and until the last year, the influence of that trade on the revenue of the work was hardly appreciable.

In 1835, when that line paid into the treasury of New York nearly one million three hundred thousands dollars, the tonnage of western produce coming from other states to Buffalo, and that passing up the canal to the lake, *was but six per cent.* of the whole tonnage constituting the trade of the work. The residue—namely, the 94 per cent.—was made up along the line of the canal itself, and consisted of the produce of farms which were chiefly brought into cultivation by the improvement of the forests to which it became the out-let, of the mines which owe to it their value, and of the supplies of towns and cities on its banks, the very foundations of many of which were laid after the commencement of the construction of the work.

I by no means desire to depreciate the value of that western trade, which, notwithstanding its present inferiority, I regard as by far the most important of the prospective resources of the line, and the city which it sustains. The increase of its value in one year—the last year—was 71 per cent. over that of the preceding, and there is every reason to believe that the rate of its increase will continue to be progressive. The great country surrounding the lakes and the tributaries of the Ohio has but begun to receive the population which it is capable of sustaining, and has hardly begun to send off the surplus produce which is not required for the supply of the emigrants.

The hundred thousands persons who annually go westward by the packets on the Erie canal, and the unestimated thousands who cross the Alleghany by some other route, are almost lost in the forests and prairies. They are now but seeding the ground; and we may ask in admiration, what will be the effect of the Erie canal ten years hence, when the country is in some measure populated, and the reaping shall commence—and the splendid schemes of improvement now in contemplation or in progress, leading from the interior of Ohio, Indiana, Illinois, Michigan and Canada, have begun to pour the produce of those states, destined for the city of New York, into the lakes?

The trade of the Ohio, which is one of the objects sought by the improvement we have on hand, is not less important. Its tributaries, and those of the stream of which it is a tributary, spread over a still wider area, and penetrate a still richer country. The number of steamboats, which may be regarded as the measure of the trade, is many times more numerous, and increasing far more rapidly than the number of those on the lakes.

The Pennsylvania improvement last year, though operating under most unfavorable circumstances, and in only the third year of its existence, carried to and from Pittsburg, over the ten inclined planes and broken line, a quantity of goods and produce exceeding by a vast amount that which circulated between New York and Buffalo.

And this line through Pennsylvania, from the Ohio to tide water, is open and successful. This is not the time to draw a comparison between that work and the one which we are constructing; but they who are disposed to doubt the success of the James river and Kanawha improvement, or its ability to bring the trade of the Ohio to Richmond, and forward supplies to the west, would do well to examine the list of articles transported on that line. Perhaps they will find in the fact, that there were carried from Pittsburg to Philadelphia, the last year, more than *one million four hundred thousand* bushels of wheat, and *three hundred and thirty thousand* bushels of corn; and towards Pittsburg from Philadelphia and the intermediate places, *twenty thousand tons* of merchandize, and *nine thousand tons* of groceries; an argument worthy of their consideration.

Though these articles are among the most important carried on the line, they constitute but a small portion of the aggregate tonnage.

What will be the amount carried on the James and Kanawha improvement, or what influence the superiority of its termination on the Ohio, and the advantage of its climate may have on its success, we may leave for the event to determine, and for a rational public to anticipate. As things are, it remains but for this company to go on as they are going—to expend their present capital to the best advantage—and trust to the evidence which the works they finish will afford, and that perseverance to which they owe their present existence, for raising the balance.

THE NECESSITY FOR GREAT CARE, AND JUDGMENT, IN SELECTING STONE FOR LOCKS, AQUEDUCTS, AND OTHER PUBLIC WORKS.

Extract from the Proceedings of the James River and Kanawha Company.

To the President and Directors of the James River and Kanawha Company.

Gentlemen—the chief engineer has permittted me to peruse his report of the 19th instant, on the subject of a change of plan, by the substitution of wooden locks for stone, as a temporary measure, which was referred to him and myself by the board in October last.

By this report, it appears that the saving of outlay in the first instance, is about 8000 dollars per lock, and the real loss on a final result, about 370 dollars per lock. This view of the change is quite as favorable on the side of the stone locks as I could make it.

It is well known, that from a point a little above the Rivanna river to the Blue Ridge, along the valley of James river, or in the vicinity of it, there has not been found any stone fit for locks, with two or three exceptions—and these exceptions only gave stone of bad shape, and which worked into locks with great expense.

I have just returned from a visit along the Erie canal; and an examination of the locks (built 16 to 19 years past, of stone, which was then thought by all who examined them to be good,) has proved that we ought to be very particular in our selections of stone for locks or aqueducts. In many of those locks I now refer to, the stones have scaled off on the face, and become decomposed, so as to require blanking to keep them up, until new locks can be erected; and so particular are the board of commissioners of that canal, in their selection of stone for new locks, that they are transporting stone from 50 to 120 miles on the canal to build locks and aqueducts.

The aqueduct over Genesee river, consisting of nine or ten arches, of 50 feet chord each, was built of stone, which was approved at the time, and found in the quarries in the vicinity; they have failed entirely, and a new aqueduct is now building with stone brought 120 miles.

The masonry of a lock is the most trying and severe test in which stone can be placed—and the greatest care and caution should be taken in selecting them.

I believe it will be found, that by erecting wooden locks, and placing them on the hill side of the canal, so as to build a stone lock in its proper place next the towing path, and by taking time to select good stone, from a quarry near the canal, and of a quality that will come out with good parallel beds, and cut well, a lock can be built of such stone when brought 100 to 150 miles on the canal, cheaper than the locks can now be erected. And I add to this, that in the choice of good stone and good cement, and selected mechanics, it is probable the real worth of the lock would be double the value of such as we should be obliged to build, if we persist in the construction of stone locks now, under all disadvantages.

I passed through the Pennsylvania canal, between Pittsburg and Harrisburg, in June last—and found three fourths of their locks were wood, backed up with dry walls. These, I believe, are intended to be permanent, and to be repaired from time to time as the wood decays, which can be done in winter.

Taking a view of all the bearings of the question referred to the chief engineer and myself, I concur with him in recommending the wooden locks; and I would advise the board to have a model made of one inch to the foot, representing every piece of timber, and the manner it is put together—so that contractors cannot mistake the intention of the board, and may understand their own proposals.

Respectfully submitted.

BENJ. WRIGHT,
Consulting Engineer.

Richmond, Nov. 27, 1837.

For the Farmers' Register.

THE LAWS OF SUBSISTENCE AND OCCUPATION CONSIDERED, IN RELATION TO THE AGRICULTURAL IMPROVEMENT AND GENERAL WELFARE OF THE COUNTRY.

Of all the errors, (and there are many and grievous ones,) in the present system of political economy, there is none so great, and utterly fallacious and mischievous, as that of viewing manual operative *human* labor, as a mere dead or barter commodity; as if *its* compensation, value and demand, were merely regulated and required only by the wants of the few rich; as if *its consumption*, although forming the *mass* of mankind, had nothing whatever to do with the means, power and purpose of all human exertion and industry, existence and subsistence: just as if the few rich *choose* to *demand* it—very well; and if they do not, it must suffer and abide!!! and the rich receive no injury!!

In thus considering that three-fourths of mankind, and more, are not *men*, nothing can more lamentably show the withering, blasting effects of *aristocratic* feelings and principles; for *this* is the foundation of it all. The earth was created for the use of *man*, without any regard to any distinctions of wealth or poverty, manual or intellectual labor, size or color. In one respect, all are upon a perfect equality—*the stomach;* as this is filled, so are nations prosperous and advancing, or poor and declining. If the rich man has his venison, turtle, canvass-back ducks, wood-cock and asparagus, the operative *must have*, and with equal if not superior enjoyment, his fat beef, pork and mutton, bread, cabbage and potatoes. No *individual* can be cheated out of and deprived of his *natural* rights, without a corresponding loss to *all*. Feed the *mass* upon rice, indian corn, potatoes and dry bread, and what is the result?—the utter stagnation of agriculture; no flocks and herds to maintain, create and increase the fertility of the soil, and with the consequent due economy; no price, for there is no demand to justify improvement, no means to accomplish it; all is stagnant and dead, destructive and impoverishing. If agriculture is drooping and dead, what profession is alive and flourishing? None. Agriculture is the foundation of all prosperity, and its prosperity depends upon all men being able to subsist according to the natural law of subsistence. Set the people to work according to the law of occupation, that is, every one being employed according to his *natural* taste, capacity, and power, and then all will have the means of legitimate subsistence; food will then be produced according to the law of man's subsistence, and the consequent and attendant true principles of agriculture, and all will flourish together; deficiency of food and excess of population, will then be things to be talked of as occurrences gone by. Yet political economists seem to consider low wages and excess of population, as evils of the people's own making, and of which they alone are the sufferers; and hence the Malthusian theory of "moral restraint," for their exclusive practice and benefit! How ignorant was the founder of that wretched system of the true system of the laws of the occupation and subsistence of man, and of the production of his food!

Nothing is plainer and more obvious, to me at least, (and the world will understand it too, by-and-bye, to its immense advantage,) than that the *power and means* of the production of food, are in exact proportion to the *nature* and *extent* of consumption; the true law of the production of food, being in exact accordance with the law of *man's legitimate* subsistence. That if he subsists upon bread or potatoes, or rice or hominy, or animal food alone, which nature did not form him to do, just so are his means of procuring subsistence curtailed, with increase of population; but as he subsists upon animal and vegetable food in certain proportions, and upon all their varieties, as he was obviously organized to do, exactly and duly, so are the power and means of increasing his means of subsistence, with increase of population.

This is certainly a more comfortable doctrine than that of Malthus; that most hideous, blasphemous and atheistical of all theories ever broached by ignorant man; but not intentionally so: but it is founded upon the most consummate ignorance of first *principles*, and utter ignorance of any knowledge whatever of agriculture, grafted upon narrow, exclusive, aristocratic habits, actions and principles of thinking. Audacious and presumptuous man! professing, too, to be a teacher and follower of the doctrines of him "who condescended to assume the garb of a Galilean peasant;" did you believe that all this world's productions were made exclusively for the few, and not for *man?* Did you believe that the producers of them were only to have a mere existence? although the physical organization of all is identically the same as to subsistence. Did you discover any difference between the teeth, palate and stomach of the noble, the country-gentleman, the rich merchant, and the mechanic or cultivator of the soil? No; they are all in *this* respect the same. The rich man may have his beef, mutton and pork—venison, turtle and wood-cock—bread, potatoes and cauliflower, &c. Nature has evidently so ordained it. But the laborer cannot be pushed from the board of beef, mutton, pork, bread and potatoes, and many other necessaries, luxuries and comforts, with impunity. Nature has ordained this too. Man must have his *natural* rights, or the board, and all that is upon it and *about it*, will ultimately disappear together. The silent wrecks of the fraudful monopolizing exclusive system, are visible in every quarter of the globe. They are true and unerring land-marks, to guide us and many future ages, if we will only read them aright. But it is not the "cloistered philosophers," the "elegant historians" or the dillettante tourists, that are the men to do this. It must be done by men who have lived, worked, and fed with men; and these will tell the world, man cannot be cheated out of his natural rights, as man, with impunity.

It is very remarkable, that Malthus never once inquires—"Have nations fulfilled their duties so as to obtain the means of subsistence?" Nothing can explain this but his utter ignorance of the laws of occupation, subsistence, and the production of food, and their operations and effects on the one hand, and his strong political bias on the other. Such a man ought not to have written upon *this* greatest and most important of all questions. It was deeply criminal. No man ought to write upon it, who is not prepared to see, feel and understand, that *all* men are *men* equally with himself; he must be prepared to do his duty to himself and society, and at the same time believe that all other men are *formed* to do that duty to themselves, to each other, and to him; that they are *formed* to subsist as he subsists; and that they are to be occupied in their various callings, free and unshackled, as he is occupied; to obtain their legitimate subsistence as he obtains his: he will then probably come at something like the truth: but never with the ignorance (of first principles) and the political feelings of Malthus. Malthus has written a glorious book for the selfish—(forced to be by law) idle, rich, and titled: of course *they* cried up his monstrous, outrageous, and really blasphemous theory, as a master-piece of philosophy! To make the scorn and usurped superiority of the adventitious aristocrat a fixed and satisfied principle, is an act of fearful error and mischief.

The besetting fault, and the true cause of the utter fallacy and consequent complete failure of the operation of the laws and theories of statesmen, political economists, philosophers, philanthropists, &c. are in their viewing, partial and local things, as the sole and main causes of great and universal evils; and partial and local remedies, as the great and universal ones. Consequently, their remedies are ever in direct variance with the greatest and most important laws of nature; hence they cannot succeed. Deficiency of food and excess of population, affect the condition of *all;* they arise from the ignorance and errors of *all;* they must be removed and remedied by the just observance of the laws of nature by *all*. How then can *partially* checking population in *one* class, remedy the existence of universal deficiency of food and excess of population, when all are placed in utter disproportion of the law of occupation, and the mass with that of subsistence?—thus, all making the production of food for the mass defective and deficient. If the whole *non*, undue, disproportional and defective observance of the law of occupation, makes the production of food deficient, how then can any *partial* and *arbitrary* check to population, even if practicable, possibly remedy the evil, leaving the real causes still in full operation as before?

The production of population belongs to the laws of nature; man has nothing to do with either checking or regulating its increase, or otherwise. The more he does so, the more mischief he will create. His duties are to provide due and sufficient occupation; the food will then duly follow the consequent full and legitimate demand, and consequent just compensation (wages) for it. The power to do so being *then* fully equal to the force and extent of the demand, for as is the demand for food, so are the powers and means of creating it. Who can doubt that the laws of nature are in any degree inadequate to this purpose!

It is well put by H. C. Carey in his 'Essay on Wages,' that "the trade of population is the only one that has heretofore been free; and it is to be regretted, that those who are in favor of loosing the shackles which have bound all others, advocate restrictions upon that which has heretofore escaped." If the trade of population has always been free—and God forbid it should ever be (morally and legitimately) otherwise--well may there be deficiency of food and excess of population, whilst nations are restricted in all sorts of ways, both as to their natural subsistence and occupation! *Let population alone; duly and justly employ it; and it will then be duly fed.* If it is thus duly fed, the production of food will then be full and ample. Deficiency of food and excess of population, will then wholly cease and disappear. *Let* rich and poor marry as they may. All this, political economists and statesmen, and even farmers and manufacturers, have yet to learn and understand. If they do not know these (when known) very simple and very obvious *first* principles, what errors they must commit! Not knowing them, they have done so.

Malthus has clearly and most indisputably proved (with some facts innocently, because ignorantly, somewhat stretched as part of his theory,) that deficiency of food and consequent excess of population, poverty and misery have existed in all ages and countries: thus opening the door to the investigation of the greatest and most important subject which ever did or can engage the mind of man. But surely the cause cannot be what he has conceived it to be, and still less the remedy. He says man has a *tendency* to increase faster than his food; so have all living things, animal and vegetable, from the musquito to the elephant, from the thistle to the oak, the same *tendency*. If animals have a tendency to increase faster than plants, (if I may so express it in a sort of Irish fashion for want of a better,) plants have the same tendency to increase faster than animals. The shark has a tendency to depopulate the ocean; the herring has a tendency to fill it. The lion and tiger, the thistle and thousands of other plants and weeds, little things as well as great, have a tendency to drive man out of existence. Yet all these things remain as duly proportioned as ever. We *know* the sun and other forces are adequate to sustain, light and heat the globe itself, and therefore we *may know* that there are other laws, although we may not yet have discovered and brought them into action, equally and correspondingly, adequate to duly and fully support *human* life. Nature has equalized and adjusted all these things so exactly and truly, that there is nothing either to excite man's fears regarding them, or to require any *interference* of his to regulate them, or to make any *new laws* respecting them.

I believe no one has yet investigated the question and principles of how the *occupations* of a nation govern the means and modes of subsistence, and of how the powers and modes of subsistence govern the production of food.

The great essential means of the prosperity and well-being of mankind, are the due observance of the law of occupation. All being duly occupied, they will be duly paid, and consequently, duly subsisted; the true principles and practice of agriculture will then consequently follow. With these, education must go hand in hand; and to establish these, there must be good government. If these laws are not duly observed and established, how nugatory must be all compulsory laws of government, directing and controlling the people! And how unnecessary, if they are observed and established!

Every man is born with certain powers and abilities to enable him, not only fully to support his own existence, but likewise that of his children; that is, provided all other men duly exercise their powers and abilities, and all duly and equitably exchange the products of their labors with each other. If the sexes, rates of increase, kinds and quantities of food, animals, plants, fishes, birds, land and water, heat and light, seasons, *every thing*

—are all duly and exactly proportioned to each other, surely the natural tastes and abilities of all *human* individuals, are as justly and equally proportioned to each other, so as to duly, fully, exactly, and proportionately, supply each other's wants. Whether a certain piece or kind of timber, or a certain other piece or kind, is made into a table, a chair, a box, or a coffin, or something else, or any thing else, *may* be of no sort of consequence; but not so whether a *man* is *made* a ditcher or an idle lacquey, whom nature intended to have been a blacksmith or a carpenter; or is made a farmer, who ought to have been a cotton-spinner; or is made a clergyman, who ought to have been a butcher; or a lawyer or physician, who ought to have been a drayman; or is *made and forced to be a lord*, whom nature intended for a stage-coachman or ostler; or who is made a beggar and convict, who ought to have been a secretary of state; and so on with all others out of their places, and in no places.

No man can ever be truly happy, virtuous, industrious, healthy in body and mind, and in all things truly right and securely and fully successful in life, who is out of the place or profession assigned him by his *natural* tastes, capacity, and powers. How wrong, then, are all artificial distinctions, privileges and powers, slavery, &c.! It is this which causes excess of population, keeps wages below the power of the observance of the law of subsistence, consequently depresses agriculture to the lowest possible condition. Slavery makes nations poor, stationary and retrograde, because it makes the different classes to supply each other's wants so unduly disproportioned to each other. *It is this disproportion*, which is the real source and immediate cause of all the poverty, idleness, and consequent misery, and crime of Ireland.

Were all placed in their natural and legitimate stations, violent revulsions in trade could never occur, and bankruptcies very rarely; "competition" in trade, the curse of society and the destruction of honesty, integrity and fair dealing, could have no existence. Trade, commerce, the law, medicine, and the church, &c. are called very uncertain and precarious professions; and why? They are not inherently so; but because the folly of ignorance, pride, prejudice, caste, &c. are ever unduly filling their ranks. No wonder then the endless and periodical failures in them, from two such causes as undue numbers, consequent undue and ruinous competition and speculation in some, and the unfitness of individuals in all.

It is the due proportions of the population in the different professions which is the cause of the prosperity and high wages in nations and colonies in their infancy. It is the infraction of this great law, (the law of occupation,) produced by evil laws, institutions, opinions, and habits, which creates excess of unemployed population, consequent low wages; these causing the destruction of agriculture, manufactures, and commerce, and consequent national old age, decrepitude, and decay. Prosperity ought to be the greatest, and wages the highest, in the oldest countries; and would be so were the law of occupation duly and fully observed, and the observance duly proportioned. Political economists may, yet awhile longer, tell us this cannot be. When I see the ocean filled with nothing but putrid herrings at one time, and at another, with nothing but sharks devouring each other—and the buffalo chasing the lion—the vulture skimming the air in pursuit of insects—and the swallows flying away with lambs and kids—when I see the orange and the pine apple perish in the south, and more plentiful in the north than grass and wheat—I, for one, will believe them.

All national prosperity, stability and permanence, as well as all individual well-being, are dependent upon the different branches of *productive* industry being duly proportioned to each other. As this happy state of society is becoming more and more established, nations will become more and more prosperous, industrious, civilized, happy, stable and permanent: and as they go on, more and more so, and interlocked and identified with each other in the interchange of the various productions of the different *latitudes*, by means of commerce, (the great civilizing power,) promoting each other's prosperity, wealth and happiness —wars, (idleness, poverty, misdirection of occupation and non-intercourse, being the cause of them,) poverty, deficiency of food, excess of population, &c. &c. will gradually cease, and be no more.

Could we but ascertain merely the proportions of the different professions of the populations of the once vast and powerful, but now wholly extinct, empires of the east, from their rising to their setting, we should at once see the real cause of their "decline and fall." In all ancient empires, neither national nor individual legitimate industry, powers and means, were called into action; they had no legitimate existence or direction whatever. All and every thing were ropes of sand; there were no bonds of union, domestic or foreign, none were dependent upon each other's industry; all was consequently brute force, violence, fraud, oppression and aggression; and consequently, they fell, not by the acts of any individuals, for individuals have no such power, but by the radical and inherent defects of their whole national and individual relations. They had only five classes; soldiers—the idle unproductive rich—slaves—what may be termed the idle productives—the builders of temples, pyramids, pillars, tombs, mausoleums, theatres, &c.—*and the miserable cultivators of the soil.* Their fate was inevitable. How entirely different are the conditions and relations of modern nations, both internally and with regard to each other! Yet how far from what they ought to be!

In the immense mass of public buildings in ancient times, there are none which, after their erection, added any thing to the national wealth, or opened, in any degree, the channels of productive industry. This was an immense and incalculable evil. An ancient emperor, or patrician, fed hundreds of wild beasts; hundreds of modern agriculturists and manufacturers consume the *same quantity* of food. The former left nothing but their skins; the latter add millions to the national wealth, and create means for the support of thousands in perpetuity.

What a wretched political economist is he who says, that he who builds palaces, keeps dogs, hunters, race-horses, gives expensive entertainments, &c. employs the poor, and benefits hundreds! and that every man has a right to spend his income as he likes! Is there any error so great and mischievous as this doctrine? The Duke of Bridgewater laid out his fortune in making his canal. George IV. and many nobles, spent the products of other men's industry upon palaces. Who can calculate the difference of the effects of each, upon the national industry and wealth for a hundred years afterward? The canal employs thousands and millions, directly and indirectly, in *productive* industry, for ever afterwards; the palaces engage thousands in consuming idle, unproductive existence only; destroying the products of the industry of others, without rendering any equivalent productive return.

When we view the hordes of the idle rich and the idle poor—the unemployed, and the wrong and unproductively employed—the useless in all professions—the tax-gatherers—soldiers and naval sailors—the useless hangers-on and dependants of nobility—beggars—thieves---convicts---gamblers—horse-jockeys—the army of government officers and laborers—the government aristocrats, (the fund-holders)—the sick, &c. &c. we shall find, in England at least, that it is not the industrious many who support the idle few, but the really industrious productive few, who support the idle and unproductive many. The really improving productives in England and the United States, are greater than in any other countries; hence their present condition. If *all* were any thing like productively occupied, and industrious, the danger would be of far too much production of food, instead of too little, and constant unconsumed *excess*, instead of *deficiency*, would then be the result, *were the observance of the law of occupation not duly proportioned;* this being the means of duly proportioned production, and the check to undue and excess of production of some things, and deficiency of others. For the want of the observance of the law of occupation, even now excess of production often takes place in agriculture, and particularly in manufactures. Before the establishment of manufactures in the United States, agricultural produce was sometimes almost wholly unsaleable.

With the law of occupation, the law of primogeniture is wholly inconsistent, and consequently the law of subsistence is violated, and the true principles of agriculture cannot be practised and developed. How can any right, real improvement of the soil, to the proper extent, take place in England, with the law of primogeniture and entail? Under the operation of these laws, neither the tenant nor landlord can do justice to the soil. The tenant, at will or under lease, and in both cases at exorbitant rent, with no permanent interest in the soil, with all he does, being of no advantage whatever to his children, but the contrary—will he, can he, ought he, to improve the soil? Will the landlords do it? No. In ninety-nine instances in a hundred, they are unfitted by nature, and in all, almost wholly unfitted by education, habits, pursuits, &c.; spending their means upon palaces, living in London or abroad, horse-racing, hunting, gambling, &c. Then how have the improvements in England, as far as they have gone, (and much has been really and wonderfully done,) been accomplished? By the force of the demand of the *non-agricultural* population, by the vast demands of the manufacturing, mining and commercial population. What would have been the results had the occupiers been the owners of the soil, and the owners the occupiers?

Why have the owners of the soil in England, who have been the occupiers, not in general improved their estates better, equally and proportionately with the tenantry? for it is a fact that they have not done so: because they are generally the *hereditary* owners, *rarely fitted by nature for the occupation*, and still less so by their education, associations, habits, and other pursuits. The *hereditary* owner of a moderate estate, in the midst of large hereditary estates, is placed in a most perilous and dangerous situation; his habits are those of the opulent aristocracy by which he is surrounded, and having no rent to pay, he fancies himself a great deal more secure than he really is. He identifies himself far more with the rich owners of the soil, than with the tenant occupiers.

To investigate the real positive utility of, in themselves, an *idle, unproductive, hereditary aristocracy*, would be a curious and most important inquiry. They promote literature, the fine arts, *certain* forms of good manners and civilization, morals and habits, cleanliness, &c. What more? Are monarchies and aristocracies to restrain and suppress the effects of ignorance? to govern society by *fear* and subservience in the *absence* of knowledge, morals and principles? It would appear to be so.

The primary, and great source, and cause, of the real impediment to the right advancement and prosperity of the national and individual interests in the United States, (and all other countries,) at the present moment, are the *deficient* proportions of productive industry and occupation to the agricultural portion of the community, and the too great proportion of the soil in cultivation to the *existing* population. And though little suspected or thought of, these are the main causes of the present deranged state of all the commercial relations. No country, and the currency of it, can be in a healthy and stable condition, until all the manufacturing and other branches of productive industry are duly proportioned to the agricultural, and until the soil in due cultivation is duly proportioned to the legitimate wants of the existing population.

The present condition of the United States, is a transition one, from a purely agricultural state (the worst possible a nation can be in, next to the purely savage and pastoral,) to *varied* occupation. There are yet too many farmers and too few of other productive professions; yet now sufficient of the latter to press upon the existing deficient means and defective system of subsistence, induced by the excess of agriculturists and the deficiency of a healthy productive non-agricultural population. The remedy: More non-agricultural productives, to produce a *consequent* improved system of agriculture upon the soil now occupied, (*vide* England) which will be in no degree promoted by importing grain from countries which ought to consume it at home. To encourage the importation of food, (the *defrauded* surplus of unduly fed populations abroad,) to lessen and check the existance, growth and extension of home non-agricultural industry and production, with a view to increase, or in any otherwise to increase, the already by far too great extent of the occupation (for cultivation it cannot be called) of the soil, would betray the utmost extent of legislative ignorance of the true interests of society. To those entirely unacquainted with agriculture, it would obviously appear, that the more of a population is employed exclusively in agriculture, the greater would be the production of food. The reverse is the fact. The more agricultural a nation is, and the worse and more unproductive is and must be its agriculture. There is a sad and most fallacious view of this sort in the late report of the Secretary of the Treasury, (1837.) The true productive, and *increasingly* productive, and *really economical* system of agriculture, *can* only exist with the bulk of the population otherwise productively employed than in agriculture. To those who understand the true principles of agriculture, all this is abundantly evident; to those who do not, the example of England will abundantly prove it. No country was in a lower condition than England when purely agricultural, and that at no distant date. She was sunk in poverty and barbarism, when Italy was prosperous, wealthy and civilized. As the agricultural population proportionately diminished, and other productive professions increased, exactly did her prosperity, wealth and power increase, with at the same time endless and most heavy drawbacks and burthens upon agriculture. What would have been the condition of England now, had there been a just and economical government, and the soil had been placed upon an equal footing of freedom and security with her manufactures and commerce.

The scarcity of food of late in the United States, I foretold many years ago. But not because there are too few employed in agriculture, as hinted at by the Secretary of the Treasury, but because the system of agriculture created during the period of the nation being an almost purely agricultural one, is still pursued with an increasing non-agricultural population. The agriculture of the country has not yet improved with and by means of the non-agricultural population; but it will most assuredly do so, if that population is not *madly destroyed and perverted from its present occupations.*

The view taken by the present political economists of *wages* and *human* labor, its supply and demand; of deficiency of food, excess of population, their causes, operations and effects, are most fallacious and mischievous, and will ever be so, so long as the *labor of man* is merely viewed as a common dead commodity. A far higher view than this must be taken of its operations and effects. They have yet to learn that *low wages* are the primary cause of excess of supply of labor, and not the effect in the first instance. The two unquestionably become cause and effect upon each other.

The causes of too low wages are the ignorance of the people, the *equal* and corresponding ignorance, and the narrow, selfish, short-sighted views of capitalists, as to their own true and permanent interests and those of the operatives—the interests of both being intimately and indissolubly bound together—but above all, from the undue, disproportioned, and non-observance of the law of occupation. *High wages* are advantageous to all, more or less so directly and indirectly, but to none so much so as to the farmer; they give him better prices, they enable him to cultivate the soil by the only true means of improvement and increasing fertility, and with the greatest economy of labor, *in requiring the due proportions of grain and cattle crops, &c.* The farmer who advocates low wages, commits a quadruple suicide. The manufacturer who advocates the same, cuts the throats of the far greatest *majority* of his customers. The manufacturer who pays low wages, sells a diminished quantity at a diminished price only; but the farmer who pays low wages, cuts up his power and means of production root and branch, for he destroys the fertility of his soil, and possesses no power to maintain and increase it; that is, if wages are *below* the bread and meat power of subsistence, which is the natural law of subsistence. The profits of the farmer will be the greatest and highest, when all have the power and means of obtaining all that is essential for the due, healthy, legitimate existence of man; for then will prices be the highest, or in other words, the most duly proportioned, and the labor required, the least possible. The prices of all the different productions are always proportioned to each other exactly as the law of occupation is observed. All the other productive professions have always been the least duly proportioned to the agricultural, (the latter being in excess and the former deficient,) so have the profits of the farmers been usually the least.

Were the different professions all duly proportioned to each other, far less land would be in cultivation in proportion to any existing population, than now is; but the land in cultivation would be many times more productive than before, and at much less expense. All this may appear paradoxical enough to those who have not studied and investigated the operations and effects of the due observance of the laws of occupation, subsistence, and the production of food.

With most political economists, (and farmers as well,) "capital" is every thing—the panacea, the power, the means, the end, the object, the pursuit, the every thing, the all-in-all. Capital is certainly a good and essential power, the product of skill, knowledge and industry; but it is not the first of all essentials in national prosperity, but only a very secondary one. The first is *system*—the primary *unbought* power and means of production. Of what avail is capital to the agriculturist, if the laws of occupation and subsistence are not duly and legitimately proportioned and observed? He may build, make fences, drain, lime, and apply what are foolishly called artificial manures, &c. &c. and the nature and extent of the public demand *compels* him to have a large undue proportion of exhausting crops, and the same crops too frequently repeated, (the greatest of all errors in agriculture,) and withholds from him the means of duly maintaining and increasing the fertility of the soil, stock being far too little in demand. It is *system* which is the all-in-all to him, and this he must be enabled to pursue, by the just and full demand of a legitimately occupied, and consequently, legitimately fed population. Without this, capital is of no avail. It is this which will create it; aad which has done so, so largely, in England, and might have done so a hundred-fold more, were the laws of occupation and subsistence more legitimately observed than they have been, and are.

The true system of agriculture would be—*all the grass* crops in succession, according to their respective periods of duration, with *all* the crops for the subsistence of man and stock, and for clothing, &c. intervening; all according to the *latitudes* to which they belong. All those crops which return the most to the soil, are required to be grown the most, and *vice versa.* The grasses stand at the head. This would require a period of from 15 to perhaps 40 years, before the repetition of any one crop. By a wise and beautiful provision of nature, it is obvious that those crops which return the most to the soil both in vegetable and animal manure, are required to be grown the most. Again, those crops which return the most to the soil, are the least expensive in their cultivation; those which return the least are the most expensive. Nothing is plainer, than that the crops for stock must be grown in the largest proportions. The more the grass crops are cultivated under the convertible husbandry, the more will be the *whole* produce, although the arable crops will be so much less in acres, and the less will be the expense and labor. Nature has been peculiarly bountiful, kind and considerate to the farmer, if he and society will only obey and observe her laws.

The great purpose and secret in agriculture, is *system*—that is, the right and proper rotations of crops; these being right, the gradual, increasing and permanent perfect full fertility of the soil, will be mainly accomplished, at no labor and expense whatever; nature producing the intended and required effects, by the silent, costless operation of her own laws, the crops themselves producing the means of subsisting each other. If the rotation is wrong, no expense and labor will remedy the consequent errors and defects. Machinery is of very limited application in agriculture, therefore nature has given the farmer similar advantages to the use of it in other professions, by *system.* All the essential wants of human nature, are justly belonging to all, therefore if not attainable by all by means of manual labor, there are clearly means of making them so, by machinery, system, &c. Knowledge is essential to all; this could never be communicated by writing, therefore some cheap method was attainable, which is printing. There is no better guide than this principle in attempting any new discoveries: that is, in all we do we must begin with first principles.

As a proof (amongst hundreds) of how little principle and system are even yet understood and practised by the farmers in England, we shall often see them employing a *very large additional temporary* force in harvest; sowing and hoeing turnips; weeding grain crops, &c.; and, if they can afford it, even boasting of having employed a more than usual *temporary* force in some particular operation, deeming it an act most meritorious and skilful! Again, how often do we hear farmers say, "but I farm differently from others; I buy a great deal of manure, I keep stage-horses upon my farm, and I can farm as I please! I can take two or three crops of wheat together!" The fact is, the *true principles* of agriculture are the same every where, and under all circumstances. Animal manure is not the only indispensable principle—the sole panacea. If one farmer can procure double the quantity of manure another can make, this does not do away with the necessity for practising the same system. Rightly applied, this increased quantity of manure, would greatly increase the crops—but the farmer who presumes upon this aid alone, to depart from the true principles of agriculture, will find himself, eventually, a severe sufferer. The farmer who has no fixed, steady, undeviating principles of action, whatever may be his means of procuring manure, (of any kind,) is in the infancy of his profession. How wild, random, and unsettled are, as yet, the best *apparent* practices of agriculture! What would be thought of the commander of a ship, who steered now here, the next day there—one week required 10 men and the next 100—and so with others? Yet this, and far worse, is the every-day practice of farmers. I know, as yet, no reason why a farm should not be carried on with the same fixed steady principles as a ship or manufactory. If we read the works on agriculture, if we examine the voluminous reports of the English parliament, we shall find no two men agreeing upon the same principles. It is surely time that all this ignorance, for it is nothing else, *should begin to have an end.*

Manure is only one principle in agriculture; the important one, vegetable matter, (grass and other roots,) is another, and succession of crops is a third. Of all the principles in agriculture, still so obscure, hidden, and little understood, none is apparently so obvious and clear as the imperative demand of nature, that crops should be varied to the extent of all the different kinds in existence. Yet we continue to cultivate not a tythe of them, and repeat them everlastingly; and bitterly do we pay for our wilful ignorance and wretched arrogance and presumption. Even in the United States, *from the population being too purely agricultural,* during the French revolutionary war, (although wages were very high, and the people fully employed in agriculture, commerce, building, making roads, bridges, &c.) and the demands of Europe being chiefly for *bread-stuffs*—a system of almost exclusive *arable* cultivation, and consequent destructive one, was introduced and established, which will require years and years to remedy and counteract. That war, with the home exclusive agricultural population, was as destructive of the fertility of the soil, and the means and powers of its improvement in the northern states, as is the present system in the southern states, of supplying Europe, &c. with cotton, together with its present exclusively agricultural population.

I attribute the extensive and disastrous failure of the turnips, potatoes and clover in England, of late years, to the deficiency of vegetable matter, (grass) and the too close repetition of them. The crops are diseased, and consequently are attacked by insects, which are supposed to be the cause of all the mischief! This is a very shallow and very common way of investigating things, viewing the *last* effects as the *primary* cause.

The true successful period of sowing and planting all arable crops is very short; therefore, manure can only be directly applied to them with great expense and additional labor, and risk of failure by consequently sowing too late; therefore it must be wrong so to apply it, however otherwise advantageous the direct and immediate application of manure might be, which it consequently is not. Manure is much more economically and better applied to grass than to any other crops. By applying manure in the spring and fall to the grass crops, there is the least possible waste of it; the greatest possible quantity of grass is raised at the least expense, and the soil put in the best possible condition at the least expense, for the subsequent arable and grain crops.

Is straw an essential, profitable, economical and advantageous food for stock? Clearly and most obviously not. In all our investigations, we must begin with first principles. On no well regulated farm, is there more straw than will keep the requisite stock clean, dry and warm, and thus preserve the manure. Straw contains little nutriment, and is very indigestible; and if any manure is lost by the use of it as food, it is obviously the most costly and unprofitable food a farmer can consume. I know of no more speedy and certain method of bringing a farm into the hands of the sheriff, than growing an undue proportion of tillage crops, and using the straw as food.

Take *all* the crops formed for the use of man and stock in succession, the grasses intervening one to ——— years. between one arable crop for stock, and one arable grain crop for man—never more than three arable crops together—two the best.

Every crop to be repeated as distantly as possible.

Sow clover with every arable cattle crop, to plough in for the next crop.

Manure no arable crops excepting Indian corn, potatoes, turnips, millet, &c.; and applied on the surface as long as possible before planting, and applied very moderately.

The rest of the manure, with lime and plaster applied to the *young* grass; after mowing the grain stubbles, applied very moderately.

Lose no manure of any kind, liquid or solid.

Never apply any labor to destroy weeds; they will go of themselves, if the due supply of *vegetable* matter is created by the *grass* crops. Weeds are a true test of agriculture.

Although agriculture is in reality the first and most important of all human occupations, and the foundation of all others, and the first means of all human existance, all other legitimate productive occupations are the foundation of it. It is the first, yet it is the last, which can be fully perfect. The improvements and labors of individuals in all professions and sciences, are utterly vain and nugatory, unless the condition of the population is equal to sustain those improvements and labors; hence in countries where rank and titles are yet worshipped and looked up to, credit is given for many accomplished and created results, to individuals, which are due alone to the condition and well being of the public. Discoveries, and the developement of science and knowledge, are not made so much by superiority of intellect, as by developed previous knowledge arising from the pre-existing and existing wants of society, affording a guide and clue to them. The most brilliant Greek or Roman never could have discovered the steam-engine, steam-boats, coal-gas, rail-roads, &c. &c. &c.; they had no previous guiding power, influence and knowledge, to lead them on to do so. Discoverers have never been willing to admit and acknowledge this influence and directing power over their minds; credit is given them for much more merit and talent than they possess. I am fully aware of the full effect of this power and influence in my own discoveries, respecting the use of weeds, the law of human subsistence and occupation, and the discovery of (as I believe) the true system of rotation of crops consequent to them; and the discovery of the true cause of the fly in the wheat, the worm in the peach, the failure of the turnip and potatoe crops, the true system of manuring, &c. &c. My knowledge obtained in England, and then seeing the wants and state of society in the United States, made the developement of all this easy and consequetive. I have not a whit more talent than certain other men; they had, and have, no more talent than I have; previous certain knowledge, constitutional organization, and existing circumstances, place all discoverers upon a level.

Socrates and Plato would have been fools in conversation and knowledge respecting manufactures and many other subjects, with the most stupid and illiterate cotton-spinner in Manchester.

That must be the truest and best system of agriculture:

Which requires the least labor comparatively and positively.

Which requires the least *additional occasional* labor. (A very sure test.)

Which returns the greatest quantity of stock, grain, material for clothing, &c. together.

Which furnishes sufficient manure for *all* the *young grasses*, the corn, turnips, potatoes, millet, &c.

Which permits all the crops to be sown, planted and harvested in due season, without hurry, and with the least *additional* labor. By this rule, the surest and best, much of the agriculture of England is exceedingly defective.

Which permits the greatest quantity of stock and produce to be sold without creating any deficiency of manure.

Which is yearly improving and increasing the crops, and the fertility of the soil; and without essentially increasing the labor.

Which produces improving quality as well as quantity of produce.

Which diminishes the growth of weeds without any labor being expressly and exclusively applied for *their* destruction.

Which makes the crops more and more independent of seasons, and proof against the attacks of insects.

Which returns the greatest possible quantity of vegetable matter and animal manure to the soil, without at all curtailing the sale of the just and due proportions and quantities of produce, in accordance with the *legitimate* wants and demands of society. If sufficient manure *cannot* be made, either the crops are very unduly proportioned, or they are still deficient.

In short, that is the true system which will furnish food to all in accordance with the law of man's subsistence, as he is organized to subsist. The true principles of agriculture must be, and are, in accordance with that law. And man's organization must be, and is, in accordance with the true principles of the law of the production of his food; and the law of his occupation must be and is in accordance with both these.

George Henry Walker.

From the Nantucket Inquirer.

PEAT.

Peat is of vegetable origin, and is formed in cold, moist situations, where vegetables may be decomposed without putrefaction. Hence, in the torrid zone it is never found; but as we advance north it occurs, and on the borders of frigid regions it is found in great abundance; a cold humid atmosphere being peculiarly favorable to its generation.

Peat is composed of aquatic plants, such as reeds, rushes, etc., but a species of moss (Sphagnum Palustre) is generally found more abundant than any of the former class; it having the property of sprouting, and continuing to grow, while its roots are decaying.

In some peat, (as is the case with our own,) plants are found with their organization so distinct, that we can even determine their species. As is said in one of the Bridgewater Treatises, "that we may almost seize nature in the act of making coal before the process is completed," so it may be said in regard to peat; for the rude fragments of undecomposed plants we trace the process to perfectly formed peat, where a complete decomposition has taken place; and from thence to anthracite.

There is, however, a striking difference between the periods in which the vegetable depositions that form anthracite and peat took place.

Geologists agree in assigning the epoch to be antediluvian in which the vegetable deposits that form coal were made; and they also conclude, that the temperature of the earth was much higher than at present; for fossil ferns are found in coal formations, of the astonishing length of fifty feet, and other plants bear the same ratio. Now plants of this species in the torrid zone are found to approach this size at the present time; but coal is found in the temperate and frigid zones—consequently, we are led to suppose, that a higher temperature once existed in those regions.

But peat is of recent origin, as may be shown by the following facts. In Hatfield, England, as in many other places in Great Britain, Roman roads have been discovered eight feet below the peat; and their arms, axes, coins, etc. have been found in the same situation, showing that these peat bogs have been formed since the invasion of Cæsar. Nor can any traces of the great forests spoken of by this general in his 'Commentaries,' be discovered, except by their fragments, which are found in peat. And De Luc has ascertained, that the very positions of the forests spoken of by Cæsar, viz. Hercinia, Semana, Ardennes, and others, are now occupied by peat-bogs.

As orders were given by Severus and other Roman emperors, to destroy all the forests in the conquered provinces, it is evident why the remains of these once majestic tracts are found imbedded in peat: for when they were prostrated, their trunks, limbs and leaves, would check a free drainage of the water falling from the atmosphere, and also prevent in some measure its evaporation. Consequently, a decomposition of the foliage and branches of the trees would commence—aquatic plants would spring up, and decaying, add to the mass which is found in time completely to envelope the pristine forests.

An occurrence of the recent formation of peat took place in Roos-shire, Eng. During a violent storm, a forest was overthrown, and in fifty years, the people dug peat, from a mass occasioned by this overthrow.

On examining some of the peat formations which are so extensively scattered over our island, we have observed large stumps, trunks, and limbs of trees completely immured in peat. There seems to have been a deposition of shrubs, flags, and other plants, which we find but partially decomposed.

After this formation had taken place, forests sprang up, which have been cut down, probably within a century, and their fragments have aided in forming our peat bogs, which are now discovered from one to fourteen feet in depth. Without doubt, most of our peat formations have taken place since the pristine forests were destroyed, and are comparatively of recent origin. We will further state what seems a curious, but is a well ascertained fact, that not only here, but wherever the peat is discovered, it is generally found to occupy the position of ancient forests. For in most bogs, stumps, and trunks of trees are found surrounded by peat, while their roots remain in their natural position, immured in clay, or some other soil.

In some countries, peat mosses are found of great extent. One mentioned by Dr. Boate on the Shannon, was fifty miles; and Blavier speaks of one at the mouth of the Loire, more than fifty leagues in circumference.

The texture of peat is such, that it absorbs large quantities of water; and it has often happened, when bogs were very much swollen, that they have burst and deluged the surrounding country with their contents. We are informed by Deguer that the remains of ships, nautical instruments, and oars, have been found in many of the Dutch mosses; and Gerard in his history of the valley of Somme, mentions that in the lowest tier of that moss, a boat was found loaded with bricks, proving that these morasses were at one period navigable lakes, and arms of the sea, as were also many on the coast of Picardy, Ireland, and Friesland, from which soda and salt are procured. "The canoes, stone hatchets, and stone arrow heads found in peat in different parts of Great Britain, lead to similar conclusions."

One more fact in relation to peat is worthy of our notice. It is the preservation of animal substances which have been buried in it. A great many instances are recorded, which go to prove this property; a few, however, will only be mentioned.

"In June, 1717, the body of a woman was found six feet deep, in a peat moor in the isle of Axholm, in Lincolnshire, England. The antique sandals on her feet afforded evidence of her having been buried for many ages; yet her nails, hair, and skin are described as having shown hardly any marks of decay. In the 'Philosophical Transactions,' we find an example recorded of the bodies of two persons having been buried in moist peat, in Derbyshire, in 1674, about a yard deep, which were examined twenty-eight years and nine months afterwards; the color of their skin was fair and natural, their flesh soft as that of persons newly dead." At the battle of Solway in the time of Henry VII. (1542,) when the Scotch army commanded by Oliver Sinclair was routed, an unfortunate troop of horse, driven by their fears, plunged into Solway morass, which instantly closed upon them. The tale was traditional, but it is now authenticated; a man and horse in complete armor having been found by peat diggers, in the place where it was always supposed the event had happened. The skeleton of each was well preserved, and the different parts of the armor easily distinguished.—*Obs. on Picturesque Beauty*, 1772.

For the Farmer's Register.

THE WIRE WORM.

March 13th, 1838.

For the last fifteen or twenty years, our crops of corn have been materially shortened, and especially has the labor of making them stand, been much increased, by the attacks of a small worm, not unaptly (from its size and form) called the wire worm—by some called the web-worm. This little animal lives during the winter in the pith of weeds; especially the stick-weed, and has been known in this part of the state only since the practice of enclosing and non-grazing. I can remember well its first appearance. It is not the cut-worm, so injurious to newly planted tobacco and young cabbage plants; nor does it work its injury in the same way; but it assails the corn as soon as it comes up, just in the bud, where the roots and stalk spring out, and eats into the bud; not always *entirely* killing the plant—but so enfeebling it as to render it worthless. Every one remembers how fatal this little worm proved to be last year; and, no doubt, any plan proposed to avert the evil will be tried, if it be neither expensive nor troublesome. Such is one I suggest now, viz:—simply to steep the seed-corn twenty-four hours in a strong decoction of tobacco; any refuse tobacco, or even stalks, will answer. Having suffered exceedingly from this worm last year, and finding that two of my neighbors did not suffer at all, I inquired the cause, and was informed that the use of tobacco juice as recommended above had the only assignable cause for their exemption from the injury so severely felt by me and many others. I understand from them, they had used this remedy for some time, by the advice of Mr. William Skipwith, formerly of Cumberland county, whom I had long known as a good cultivator; and whose land, from a long continued system of enclosing and not grazing, was peculiarly foul, and liable to injury from the worm.

One of the numbers of your Register, some time last spring, spoke of the great injury sustained by Mr. Carter of Shirley, from this or a similar worm. If Mr. Carter will use the preventive, I propose, and it should prove effectual, I shall be well rewarded for the little trouble of making this communication, by the reflection that he has been (however inadequately) rewarded for the great benefits he has conferred on agriculture, both through your paper and by his example.

ARATOR.

From Dr. Granville's Report to the Thames' Improvement Company.

ON THE VALUE OF HUMAN EXCREMENTS AS MANURE.

This very question having been submitted a few years since to the consideration of the late Professor Hembstadt, of Berlin, by the Saxon and Prussian authorities, who were desirous to apply the contents of the city drains and cess-pools to the recovery of barren and sandy lands, in the environs of Berlin and Dresden—that eminent agriculturist undertook, in conjunction with other learned men and practical farmers, a series of experiments, which were carried on for a great length of time, and were varied in every possible way, in order to avoid all sources of fallacy. The results of those experiments, Hembstadt afterwards published, and they led to extensive agricultural operations, all of which proved successful. Professor Scnübler, the writer of the most esteemed and certainly most able 'Treatise on Agronomia,' or the best mode of knowing and treating every species of land, repeated and added to the experiments of Hembstadt, from which he obtained alike results. These he published in a tabular form, which has since passed into the hands of all the large practical farmers in Germany, and have formed the basis of instruction on manuring, in the hands of professors of agriculture, whom many of the continen al governments have, with infinite advantage, established in institutions purposely formed to disseminate useful and practical truths in the art of arming. From that table the following facts may be collected.

If a given quantity of land sown, and without manure, yields three times the seed employed, then the same quantity of land will produce

5 times the quantity of sown, when manured with old herbage, putrid grass or leaves, garden stuff, &c.
7 times with cow dung,
9 times with pigeon's dung.
10 times with horse dung,
12 times with human urine,
12 times with goat's dung,
12 times with sheep's dung, and
14 times with human manure, or bullock's blood.

But if the land be of such quality as to produce, without manure, five times the sown quantity—then the horse dung manure will yield fourteen, and human manure nineteen and two-thirds the sown quantity. *

In addition to this information, it was ascertained that the most important crops—those, I mean, which yield most profit—such as flax, for example, so extensively cultivated in both Flanders, can only be obtained in abundance, and of the finest quality, by employing human manure.

But by far the most important point of practical knowledge in this matter, put forward by the same great authorities, and the truth of which was afterwards confirmed to me by more than one great farmer in East Elanders, is, that while the manuring with human soil has produced fourteen times the quantity sown, where horse horse dung has yielded ten—the proportion of the human or Flemish manure employed, was to that of the horse dung, as one to five only; so that with one ton of the Flemish, a larger produce is obtained, than with five tons of stable manure. These indisputable truths being once ascertained, let us see how they would work practically in this country.

In England a ton of good stable manure sells for five shillings. Now an acre of arable land in an ordinary state of cultivation in England, is ma-

* It is curious how this corresponds with one of the experiments made by Mr. Burrows, an intelligent Norfolk farmer, who received the gold medal from the Society of Arts, for them. On four acres of broadcast wheat, Mr. Burrows obtained 14 quarters and a fraction of wheat, hoving emploped one quarter as seed. Had he manured his land with Flemish manure, instead of 14 quarters, he would have obtained 19 2-3 quarters for the one he employed.

nured with 20 tons of horse or stable dung every fourth year, according to Professor Coventry, and consequently entails an expenditure of £5 in that year. It then produces ten times the quantity of wheat sown. But an acre of the same land, similarly sown and manured with Flemish manure, would require only four tons of it; and entail, at the price we have fixed for that manure, an expense of £2 8s. It would, then, produce fourteen times the quantity of wheat sown.

Supposing the produce of the acre manured with horse or stable dung to be five quarters of wheat, † and sell for £15, that of the acre manured with Flemish manure, will be seven quarters, and sell for £21.

The end of this comparative farming operation therefore would be,

1st, a saving in manure, £2 12s. per acre,
2nd, a surplus produced, £6 0s. do. in money,

Total £8 12s. per acre.

A sum which the employment of the Flemish manure would put into the pocket of the farmer, above the largest numerical result he can obtain by his mode of cultivation. Thus far as to his private interest; but in this operation the public would also be a gainer, inasmuch as by means of it, two more quarters of wheat per acre would be sent into the market—a circumstance, which in the year 1832, would have prevented the necessity of importing into this country 463.502 quarters of foreign wheat, as appears from a return made to an order of the House of Commons in 1833.

But even this marvellous result of Flemish manuring, in the cultivation of wheat lands, falls into insignificance, when compared to that which it yields when applied to other cultivations, the produce of which, as I ascertained by minute personal inquiries at some of the largest farming establishments in Belgium, instead of being nine only, above the ordinary produce, as before mentioned, rises as high as 12, 15, 20 and even 40 per arpent. The same may be said of it, when applied to lands completely barren, and which, having been originally rented for one florin the arpent, have, in the course of four years, been improved, through Flemish manuring, into an easy rent of 30 florins per arpent. Examples of this sort are numerous, and many such were furnished me by the authorities at Brussels, La Haye, Rotterdam, and Berlin.

† This is assuming a most favorable return, since I find in a report on the "Allotments," in the parish of Missenden, (as a fact of which they seem proud) that the land would, under the plough, in an average year, produce only 20 bushels of wheat, or 2½ quarters; and even Mr. Burrows, in his first-rate experiment of four acres of drilled wheat, obtained no more than sixteen quarters and three bushels, making four quarters and less than one bushel per acre. Now I have it in my notes, taken under the distation of Mr. Smet, a great farmer in East Flanders, that a measure of wheat land corresponding to an English acre, manured with Flemish manure, produced last year 7½ sacks of wheat of the best quality. The sack contains four measures each, weighing 180 lbs. of 16 ounces; consequently there grew upon that acre 5,400 lbs. of wheat. Whereas, taking the Winchester bushel of wheat to weigh 60 lbs.; the acre of wheat land among the "Allotments" at Missenden, produced only 1,200 lbs. and the experiment of Mr Burrows 1,980 lbs.; while admitting even my assumption of five quarters to be correct, the acre in England would yield no more than 2,400 lbs., being less than the half of the Flemish produce.

From the St. Louis Bulletin.

THE RAFT IN RED RIVER.

The obstruction originally occupied a space of upwards of two hundred miles; and, there is sufficient evidence that it has existed for ages before the discovery of the country, while its banks exhibit indubitable proof, that it once extended not within fifty miles of the confluence of that river with the Mississippi. The annual increasement has been estimated at two miles; and once formed, the serpentine course of the stream forbids all possibility of removal, except by artificial measures, or the slow process of decay. In some places the raft is condensed to an astonishing depth, and forms what is called "the sunken raft:" a single strong log removed will sometimes liberate hundreds. The raft region may now be considered under three divisions; that from which the raft is entirely removed, extending 140 miles from the commencement; that in which the raft is cut up and pulled in pieces, and not floated off—for which nothing is wanted but a strong current, which must immediately take place—33 miles in extent; and that, lastly, which has not yet been commenced. The water expelled from the channel by the raft into the lakes, parallel to the banks as the obstruction is removed, turns and deepens the bed of the stream. At the commencement of the raft there is little or no current. This has added much to the labor in romoving the obstruction; and many of the logs removed, have floated back subsequently by a rise in the Mississippi. The removal now of a few yards of solid raft causes a fall of eighteen inches above it, and a rise six feet below. There remains only about four miles of the raft to be removed, and, when the channel is once clear, the current will be powerful and deep, and the banks on either side will be lofty and firm. Capt. Shreve declares, that all can be accomplished in *three months*, after a suitable appropriation from Congress is made.

The magnitude of this undertaking, and the results which must ensue from its accomplishment, cannot be too highly appreciated. The river is navigable for more than 2,000 miles above the raft, and through a region unrivalled in fertility Though now thinly settled, it is rapidly populating—hundreds await the removal of the raft as a signal for entering the country—and all its vast resources and natural wealth must soon be developed. The result of this undertaking once involved in doubt, as well as the permanent advantages which must ensue, are no longer problematical. The indefatigable industry, the untiring enterprise—the indomitable perseverance, and the enlarged and truly scientific designs of Capt. M. Shrieve, the projector and accomplisher of this noble national work, can never be estimated beyond their merits. His history is identified with that of the empire of the west; and his fame will endure so long as the magnificent streams with which his name is associated, shall continue to roll on their volumed waters to the deep.

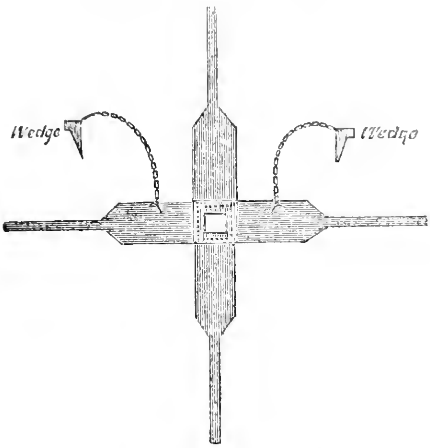
JOHNSTONE'S 'TREATISE ON DRAINING, EMBANKMENTS,' &c.

(Continued, from page 728, of Vol. V, and concluded.)

Plate XIX. *Implements for draining—described or referred to, in preceding pages of the Treatis*

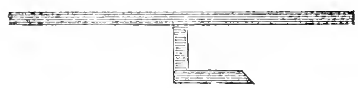
PARTS AND APPENDAGES OF THE AUGERS.

Double Wooden Handle, having an iron plate on both sides, to strengthen the hole for the rods.



Iron Key.

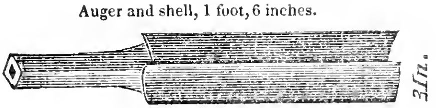
Iron key Handle.



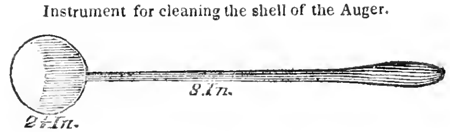
Rod—4 feet long.

Chisel faced with steel.

Auger and shell, 1 foot, 6 inches.



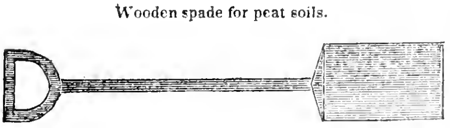
Instrument for cleaning the shell of the Auger.



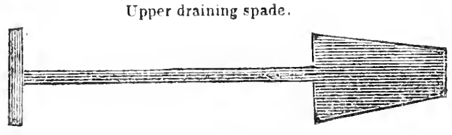
Punch with steel point.

OTHER IMPLEMENTS FOR DRAINING.

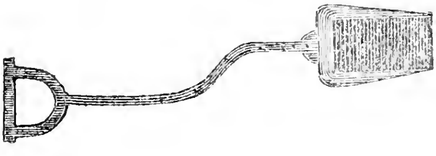
Wooden spade for peat soils.



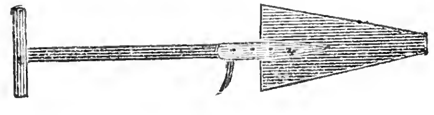
Upper draining spade.



Bottom shovel, with edges turned up.



Draining spade pointed at the end.



Scoop for smoothing and cleaning out the bottom of the drains.

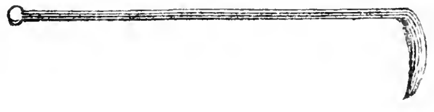


Plate XX. *Sections representing the Mode of filling the various kinds of covered Drains, &c.*

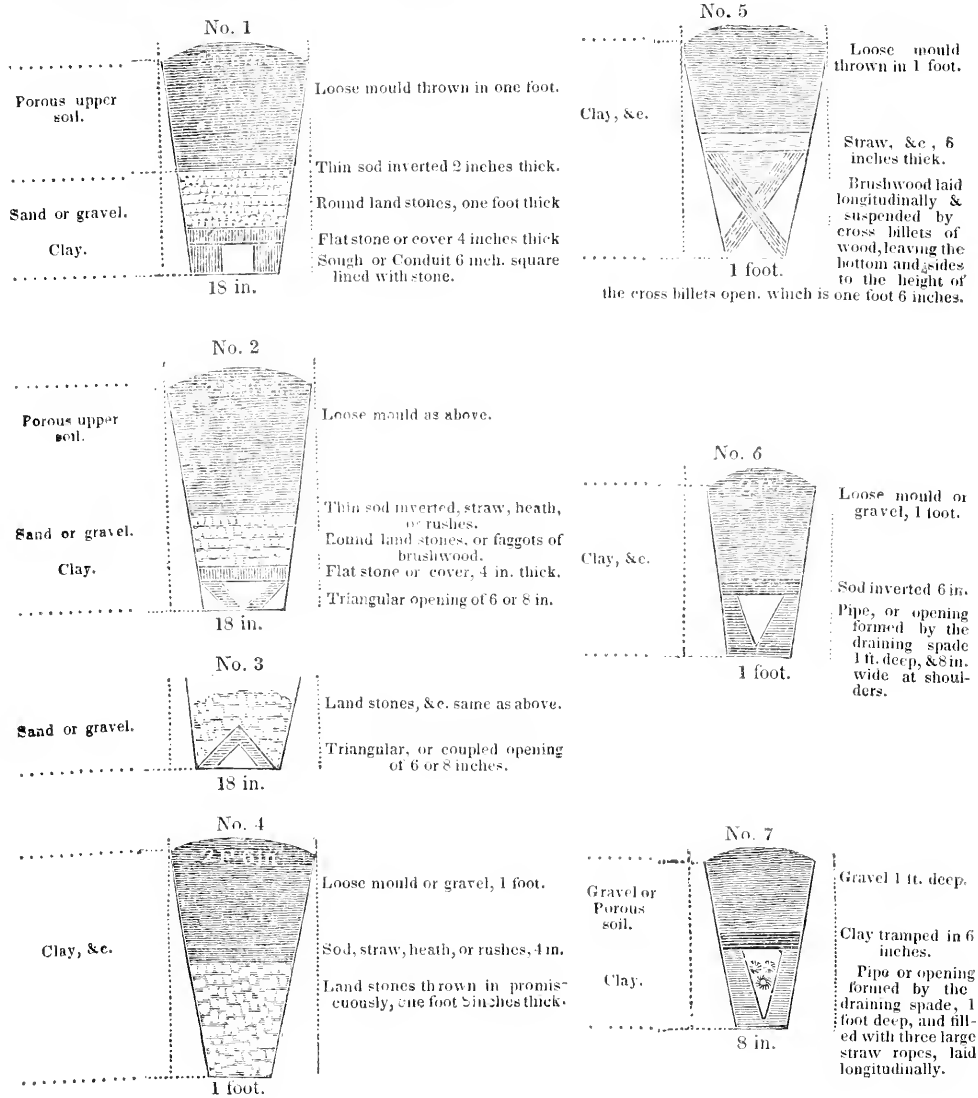
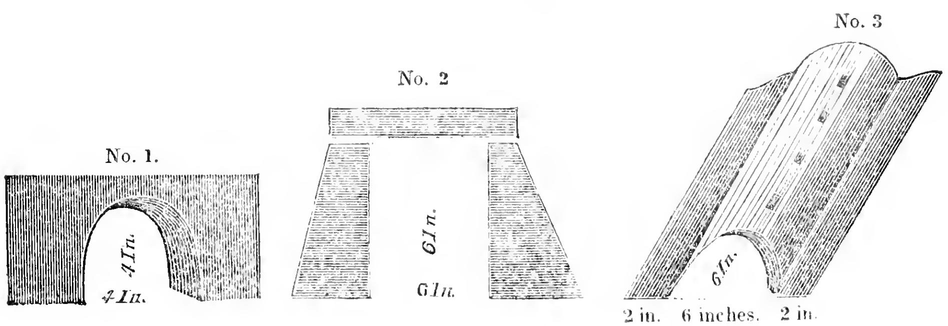


The depth of the above Drains is mostly three feet, but as the nature of the soil may require, the depth may be more or less; and the materials and mode of filling proportioned accordingly.

Draining Bricks.



ON EMBANKMENTS.

Introduction.

The object of these introductory observations is, to show the importance of embankments, in all situations where practicable, by pointing out the advantages to be gained—the losses sustained by want of them—the causes that produce these losses—and the necessity and means of preventing them.

The object and advantages of embanking are two-fold:—*First*, to defend and protect useful land, exposed to encroachment from the sea and from rivers, where the water, in high tides, and in time of floods, commits ravages upon the banks, by undermining and carrying away the earth and soil, and by overflowing and inundating the low ground adjacent. *Secondly*, to reclaim from the sea, and from large rivers, an acquisition of ground, where the same may be gained without future risk, and at an expense to be repaid by the value of the land so acquired.

Every one knows, that in Holland, the works of this kind that have been accomplished are almost incredible; and are a proof of what human industry is capaple, when its exertions are called into action, and when self-protection and interest are the objects in view.

In England, also, the valuable territory that has been acquired by means of embanking, is well known; particularly in the fens and lowlands of Lincolnshire, Cambridgeshire, Yorkshire. Cheshire, &c. and lately in Wales. In these, and in several other English districts, some hundred thousands of acres have been recovered from the sea, and from rivers.

In Scotland, little has yet been acquired from the sea by embankment; but a great deal has been done in preventing inundation, and by protecting useful land from the influx of high tides, and from the overflowing and ravages of large rivers. On the western coast of Scotland, and in the Hebridean Isles, some acquisitions have already been made; but it is calculated, that above 20,000 acres still remain to be reclaimed from the sea; and along the shores of the whole northern part of the island, in the bays, and at the entrance of large rivers, and likewise by the side of lakes, immense tracts still remain under the power of water. There is reason also to believe, that many thousand acres in the bays of Wigton, Kincardine, Aberlady, Kirkcudbright, &c. could be embanked at a reasonable expense. It may be farther noticed, that there is scarcely a river in all the country, that flows through flat land, which, for want of proper embankments, does not commit, every season, great devastations upon its banks, either rendering large tracts unproductive, or sweeping away the harvest they have reared. On the rivers Forth, Tay, Spey, Don, Beauly, Cree, Nith, Carron, and several others of inferior note, many thousand acres have already been recovered and protected; but much remains to be done in the same way, as will be more particularly noticed in the sequel. *

Land, situated on the borders of rivers, is exposed to injury from them, in several ways: by the banks being broke down, and the soil carried away; the crop injured, and sometimes swept off in time of floods; and from the rivers, when swelled with rain, flowing back into the channels and streams that conduct the water from the upper grounds into them, these smaller streams are also made to overflow their banks, and do similar injury. From the nature of its soil, its situation and climate, such land is more productive than any other. To secure its produce, therefore, is of the first importance.

From the general advantages attending embankments, it seems just to conclude, that in a country like Britain, whose inhabitants are remarkable for intelligence, and for their spirit of enterprise, and where agricultural improvements have attracted such general attention, embankments, on a large and comprehensive scale, would no longer remain neglected; especially when so great an acquisition might, by their means, be added to the productive territory of the country.

Notwithstanding the general indolence, and seeming aversion that appears, respecting the acquisition of land that might be gained by embanking; yet there are many intelligent and public-spirited individuals in both parts of the kingdom, possessing property capable of this improvement, who are fully sensible of its advantages, and have already had the advice of professional men respecting it. By this means, they can form a judgment whether the acquiring a large addition to their estates in this manner, is an object of prudence, or one adequate to the expense attending it.

In attempting to mark out the causes of this general neglect or indolence, it is impossible to join with some writers, who endeavor to trace it to the facility with which this country has always obtained supplies from abroad; or to any general impression of security which may have prevailed in that respect. There is no instance in which individuals were ever found to be guided by such general and distant considerations of policy in their private conduct. Every man is sufficiently anxious to secure the harvest of his labor, and to protect his lands from encroachment; as well as readily disposed to adopt any measure, that offers a fair prospect of territorial acquisition; and it is folly to imagine, that his endeavors will, in the smallest degree, be increased by any impression of what the country might either suffer from his negligence, or gain by his enterprise.

Perhaps a more immediate cause of the inattention to embankments may be found in the general prosperity of our manufactures and commerce, which, by affording a quicker return of profit than any other branch of industry, have hitherto attracted the bulk of the national capital. For, when we consider the great expense, and in some cases hazard, that attends embankments on an extensive scale, and particularly those against the sea, there can be no doubt that a want of capital must have operated more severely against this, than any other branch of rural improvement. At the same time, a great deal must be attributed to the inattention of landed individuals to their property; to a narrow jealousy of the prosperity of tenants; and to a want of co-operation among adjoining proprietors, arising from opposite views of interest, or different feelings of enterprise.

* The author, not being so well acquainted with the bays and shores of the English coast, does not take into calculation what may be reclaimed by embankments in that part of the kingdom.

It is, however, to be hoped, that as agriculture is every day becoming a more favorite object of pursuit—that as proprietors are now in general bestowing more attention to the improvement of their estates than formerly, and of course imbibing more just ideas of things, that the system of embankment will be as generally adopted, as, from its importance, it merits.

If a law to regulate *common drainage* should ever come under the consideration of the legislature, as has been pointed out and recommended in the Section on 'Obstacles to Draining;' one, respecting *general embankments*, would also be an object of no less importance to their nation.

In the course of this Treatise, various situations will be mentioned, both where successful embankments have been made, and where others are practicable; with such directions for executing the different kinds of *sea-dikes* and *water-banks*,* as may be applicable to them; and such drawings, including plans and sections, as will explain their form and construction, according to the situation, the extent of ground they are to defend, and the pressure of water they are required to resist.

PART I.

EMBANKMENTS ON SEA-SHORES.

SECTION I.

On defending shores from the encroachment of the sea; and protecting land upon the coast from inundation by the overflowing of high tides.

Embankments, or (perhaps more properly) bulwarks, for preventing encroachments by the sea, are, in most cases, both difficult and expensive in the execution, and often precarious in point of permanency. The power of water, when violently agitated, is not easily resisted; and when the sea is to be contended with, the means for repelling it must be of the strongest and most effectual kind. Barriers for this purpose require to be constructed with care and stability; as many circumstances occur to obstruct their execution, and to overturn the work when completed.

The sea may commit injury upon the land in two ways:—By breaking down and encroaching upon the coast, when too perpendicularly elevated above its level, and composed of loose, soft, and penetrable materials; and, by overflowing land upon the shore, which, from its low situation, is liable to be inundated by high tides.

It is necessary, therefore, in the *first* place, to point out the proper modes of guarding against, and protecting from its ravages, such parts of the coast where the soil is valuable, and where it is carried away or injured by the sea at high tides.

That water, when violently agitated, can more easily be resisted, by yielding gently to its influence, than by directly opposing its impulse, is so far consistent with truth, that it should always be kept in view, in every operation, where that powerful agent is to be managed. According to this principle, it happens, that where the beach is low, the sea is generally found rather to recede from the land, than to encroach upon it, and, on the contrary, where the shore is steep, the sea makes encroachments upon the land, more or less, according to the nature of the barrier that opposes it. Rock may remain impenetrable for ages; and although immense masses are sometimes overturned by the fury of extraordinary tides, and the incessant beating of the waves against it, yet the progress, in such cases, is slow and scarcely perceptible. But, where the sea is bounded by perpendicular cliffs of clay, or penetrable mould, intermixed with loose stones, its ravages are more rapid, and the effect of one furious tide often occasions very serious damage. This is particularly the case, with that part of the shore on the Frith of Forth, both below and above Newhaven, and to the east of Leith. The artificial barriers, both of stone, and those of wood and stone, that have been erected at these places, have failed to provide security, by their being too perpendicularly constructed, and improperly founded. The general mode that has hitherto been attempted, to stop the progress of encroachment, in these and in similar cases, is, to construct a bulwark of stone, in front of the bank, laying the stones above one another, to the height of the adjoining surface, as carefully as possible, and, forming such a slope, as to give them security. This bulwark is liable to be deranged, and often destroyed, by one or other of the following circumstances, or by a combination of the whole. First, where property is divided, and when one individual fortifies his share, and those on one or both sides of him neglect to do the same, the bulwark is thus exposed, at one or both ends, and the fury of the sea acting upon it at these open, unguarded points, soon brings it to destruction. Secondly, where this may not be the case, and the bulwark may extend along the whole line of exposed bank, the waves, when the sea is violently agitated, ascend the inclined plane, and as they return with still greater force, this body of water, rushing over the stones like a cascade, forcibly displaces them, and the whole bulwark is in time hurled down. Thirdly, the water thrown up, finds its way between the stones and the bank at top, at the place where they unite, and there scoops out the earth from behind them, by which means, the stones, thus exposed, are soon brought down by the agitation of the tide, and dashing of the waves. In order, therefore, to render such kinds of bulwark invulnerable, the base should be broader, the slope greater, and the building should be so high, as to be above the reach of any extraordinary tide. And, as a further security to the bulwark, the most effectual expedient that can be adopted is, to drive piles into the shore in front of it, to break the force of the waves. Of the efficacy of this barrier, a very strong example is given by Mr. Beatson, in his 'Observations on Embankments:'—"Some years ago," he says, "when I was on duty as an engineer at a fort near Portsmouth, built on a point of land much exposed to the sea, the waves made such havoc, that the walls on that side were constantly giving way, although built in the most substantial manner, and having bulwarks of large heavy stones besides, to protect the foundation; however, all would not do—those bulwarks were soon knocked to pieces, and several times the wall itself. At length, it

* Distinctive terms, as used in Scotland. In England, all go under the general name of Embankments.

was proposed to drive a number of piles, about forty to fifty yards from the fort. Those piles were twelve or fifteen inches in diameter, and driven in about one diameter from each other, nearly in a straight line, parallel to the wall where the waves did so much damage. They were driven into the ground with a pile engine, till perfectly firm, perhaps eight or nine feet deep, and about two feet of the top of them left above the level of high-water mark.

"After this was done, the walls received no further injury, the space between the piles and the fort being always perfectly smooth, however tempestuous the waves might be without."

Fig. I. of Plate I. is a section of such a bulwark, showing the natural perpendicular face of the shore, and how the same should be sloped, so as to resist the impression of the water most effectually. That portion of the bank marked A, should be removed, and placed in the angular point at B, so as to form a gradually inclined plane, to be faced with stone or turf, as high as the point C, or as far as D, if high tides reach that mark.

Where it may be too expensive to procure stone of the proper form and size, and where the force of the tide is not extraordinarily great, by giving the face of the bank a greater degree of slope, small stones, broke like those used for metalling roads, coarse gravel, or broken brick, may be spread upon the suface, about a foot thick; which, if well beaten down, will make a safe and durable fence. Brushwood, also, spread on the face of the bank, and well fastened down with hooked pegs, is found to answer well, when properly done at first, and carefully attended to. These last methods have been practised on the banks of the Carron at Grangemouth, and answer the purpose sufficiently well. * The wood is subject to decay, and re-

quires to be frequently renewed; but where it can easily be procured, the expense is not great.

This much may suffice for the first branch of this Section. It is now necessary to give some directions respecting the embankment of such low parts of the coast, as are subjected to inundation, by the flowing of high tides. The land here alluded to is not those bare shores that are only left dry at low water, but the flat *lands, salt-marshes,* or *sea-greens* (as they are variously called), composed of an accumulation of deposited mud of a rich quality, formed partly of the soil washed down from the upper grounds, and partly of such substances as are thrown towards the land by the tide. As these soils and substances accumulate, the surface rises so much in height, as only to be flooded by the highest spring-tides. Such have originally been the rich carses on the rivers Forth, Tay, and others, where, by embankment, and the gradual increase of soil by cultivation and manure, these extensive tracts are now become the most valuable and productive land in this part of the kingdom. The first thing to be observed, in embankments of this kind, is, to ascertain the exact height of the highest flood-tides, so that the embankment be raised, at least two feet above what these may ever approach to. When this is done, the level must be taken, and stakes fixed to the proper height, along the whole line to be embanked. Two frames of wood, of the exact form of the bank, should be made, and set up at the distance of twenty or thirty feet from each other, *exactly on the same level,* to guide and direct the height and dimensions of its construction; and the same level must be kept throughout the whole line. This is more requisite than in the case of rivers, that have a descent in their current, and where the height of the bank is regulated by the fall of the steam; for the surface of the sea-water, *being all on a level,* the top of the embankment requires to be exactly parallel to the horizon, without a rise or declension in any part.

As the pressure of the water upon an embankment against the tide, is different from that in the current of a river, it is not necessary to have it so straight, or of that uniform smoothness, which is requisite where a running stream is to glide along the side of it. It is unnecessary, however, to give it such turns and windings, or to embrace all the points and indentures of the verge next the water, which would lengthen its course, and increase the expense; but it may be carried as near the edge of the land as it is possible to obtain a safe and permanent foundation for the bank. Where it crosses any creeks or hollows, formed by the agitation and working of the tide, or by runs of water from the land, it will be necessary to increase the width of the base, in proportion to the depth at such places.

In forming the bank, the breadth, height, and strength, must be made in proportion to the depth and weight of water it may have to resist; and, in order to obviate resistance, and to lessen the pressure, the more the slope towards the water approaches to a degree of flatness, the greater will be the firmness and durability of the structure. In difficult cases, it is advisable that the surface next the water should form an angle to a perpendicular line, of from forty to sixty degrees, according to the force to be opposed, and the nature of the materials of which the mound is to be constructed. See Fig. 2. of Plate I. Where the foundation is firm and solid, the natural earth of the ground where it is erected may be employed; and will answer perfectly well for the body of the bank, and for the inner surface likewise; and where the pressure or force of the water is not very violent, the slope next it may be formed of the same materials. But in cases where the force of the tide and waves, by its exposure to strong winds, operates more violently against the bank, the outer slope should be formed, to the depth of two feet, with clay, or the strongest earth that can be most conveniently got; and that, as well as the top, covered with well swarded turf. The inner slope, or that next the field, may be sown with grass-seeds.

The stuff, for forming the bank, should be mostly taken from the side next the water, that as little of the surface within may be broke as possible —only by what is taken from the back-cut, or drain, that is necessary along the embankment on that side.

No stones should be left near the foot of the embankment; for the tide, forming eddies round them, would soon make holes, and break through the bank. To guard the bank from the impression of the water, a fence, *of stake and rice,* may be made along the bottom of it next the sea, which will last till the surface on that side is sufficiently swarded, and the mound properly consolidated. Lastly, attention must be paid to diverting any streams, or runs of water that may pass through the ground embanked, and to collect these, if possible, into one or few channels, and to give them an outlet at the lowest and most convenient part of the bank. This must be done by a sufficient tunnel, box, or pipe, according to the quantity of water to be discharged, and which must have a proper flood-gate or valve, fixed to the mouth of it by hinges on the upper side.

SECTION II.

On reclaiming land from the sea, by embankment.

It is necessary to premise, that, under this head, are included those rivers that have broad estuaries, and where the tide flows for a considerable way, leaving dry, at low water, extensive shoals, *sleeches,* or tracts of surface, which it is in the power of embankments to exclude from the tide; and where the quality of the surface is such, that, at no extraordinary expense, it may be reclaimed and converted into arable soil. Such are the Friths of Forth, Tay, Clyde, Cree, Beauly, &c. where great acquisitions of land might yet be made, at a moderate expense.

The first object to be considered, before attempting to reclaim land which at low water is left uncovered by the sea, is, whether or not the quality of the surface to be gained is such as to be capable of cultivation, and fit for the other purposes of agriculture; for, in many cases, what is exposed at low water, and might easily be banked out, is an accumulation, to a great depth, of barren sand or gravel, unfit for any useful purpose.

On many parts of the coast, however, where the sea at low water recedes so far, as to leave dry large portions of surface in the bays and creeks of the shore, the soil is of a rich and fertile kind, being rather a deposition of fine earth washed down from the land, than of poorer substances thrown out by the sea. In the friths above mentioned, and at the entrance of other large rivers, whose estuaries are wide, and in which the tide ebbs and flows, immense tracts are left bare at low water, and where the land that might be gained would amply repay the expense of embanking it. The mouth of the South Esk, in the Bay of Montrose, deserves particularly to be mentioned, as one of the most extensive and practicable instances of this kind. Indeed, this tract was undertaken to be embanked by Dutchmen, many years ago; but owing to a dispute amongst the proprietors, respecting their rights and boundaries, the undertaking was abandoned. On the other rivers that have been mentioned, much has already been done, and there is now land let at five pounds sterling per acre, that, not many years ago, was covered to a considerable depth with water.

At the mouth of the Eden near St. Andrews, much land has, of late years, been reclaimed: and much may still be gained there, by extending these embankments, on a *stronger* scale, farther into the tide-way.

Where it is intended to reclaim a piece of land that is covered every tide, either in a bay of the sea, or on the side of a large river, where the tide ebbs and flows, the undertaking will be more or less difficult, according to the depth of water, rapidity of the current, and prevalence of the winds in that quarter. Embanking, so as to exclude the sea in these situations, will also be more or less tedious and expensive, according to the nature of the materials of which the beach is composed, whether the soil is of a sandy or loose texture, which is most frequently the case; or of a clayey substance, where there will be less labor in its construction, and more certainty of its remaining secure.

Where the materials on the spot, of which the bank is to be formed, are of a sandy consistence, it is absolutely necessary to face it with stone on the side next the sea; otherwise, the impression of the waves would soon make breaches in it, and overturn the whole, in the course of a few high tides. It is necessary to give it a very considerable slope, and, at the foundation, to have the stones bedded and laid so that they bind well together. The height of the embankment should, in all cases, be two feet more than that of the highest tide. Fig. 3 of plate No. 1. represents the section of an embankment of this kind.

Where the materials of which the bank is formed are of a clayey or adhesive nature, strong turf may answer the purpose of facing the bank, and these should be well beat and pinned down as soon as laid. With regard to laying the turf, Mr. Beatson observes—"The inside slope should also be faced with turf, which may be laid with the green side downwards, as in building any common sod wall. Some expert sodders can finish this kind of work extremely neat, by setting the sod on edge, according to the slope intended to be given, and with proper mallets and beetles, they ram the earth hard behind, which consolidates the work as it advances, and tends very much to its durability. When the first or lower course is finished, they pare the upper edge of the sods with a sharp knife, quite even, by laying a rule to them, and then they go on with the second course, which they finish in the same manner, and so proceed till the whole height is completed, which, when finished properly, looks very beautiful and smooth, not a joint between the turfs being seen."

"If turf is to be used in covering the outside slope, it must all be laid with the grass uppermost, and well beaten down with a flat sod beetle made for that purpose: and for their better security, it may be proper to drive a small stake of about eighteen inches long, or more, through every sod. The sods for this purpose should at first be carefully taken up, and traced by a line, all of the same breadth, and their edges cut as even as possible, that they may make the closer joints, which will tend very much to their security till they grow properly together."

In some sandy shores, embankments may be made entirely of wicker-work. Three or four rows may be made, of different heights, and the intervals betwixt them filled with brushwood, furze, &c., forming a slope towards the water, as shown by Fig. 4. in plate No. 1. These materials would collect and retain the sand, as the tide passed through; and this accumulating and consolidating, would in time rise in height, so as to exclude the influx of the tide at all times.

When the sea is found to encroach upon a low shore, it will be proper, before attempting to execute any regular embankment, to make a careful survey of the coast which is injured, in order to ascertain if there be any local circumstances that can help to raise a natural barrier against the encroachment. Every person must have observed, that in many places the sea is continually stirring up, and driving against the coast, quantities of sand and other materials, which either remain, and serve to form either small hills or flat downs; or, are carried back by the ebbing of the same tide which brought them. In general, where the materials are of a more adhesive and solid nature, as shells, plants or slime, they rest and accumulate, and raise the land above the danger of any encroachment from the sea. But where the shore consists entirely of sand, whatever quantities may be pushed forward at each tide, are immediately dispersed to and fro by the winds, and the shore remains open and exposed to every high swell of the sea. In such a case, however, as this, means may easily be adopted for collecting and fixing the flying particles of sand; and it is certainly proper to prefer so economical an expedient, to an expensive regular embankment.

From an account of a work of this kind,* performed upon the estate of the Earl of Ashburnham, at Bembrey in the county of Caermarthen, useful information may be obtained of the manner in which such bulwarks ought to be raised.

Mr. Tatlow, who suggested the expedient in this case, and carried it into execution, remarks, that for many years the sea had been making encroachments; "and, particularly, in October 1795, had broke in and covered many hundred acres, damaged the houses, buildings, stack-yards, and gardens; and it was the general opinion, that a regular embankment must be formed, which would cost some thousand pounds, the Earl having several miles of coast."—The view," he proceeds, "that I first took was, upon a very windy day, and the shore an entire sand, which extended at

* Communications to the Board

low-water many miles. In riding along, I perceived that any piece of wood, or accidental impediment to the course of the sand, raised a hill: it immediately occurred to me, that by making a hedge at the weak and low places, with wings to catch the sand as the wind blew it in different directions, I should obtain the desired effect. I therefore directed stakes, nine feet long, to be cut and drove one foot and a half into the sand, at two feet and a half distance from each other; betwixt which I had furze interwoven, so as to form a regular furze hedge, seven feet and a half high. Of this, since last June, I have done eleven hundred and thirty-seven yards; and in October last, when I was there, a great deal of the hedge was covered: and since that time, I am informed by letter, that a great deal more of it is so, and that the neighboring inhabitants draw great comfort to themselves, from the security my furze embankment gives them, as its present appearance plainly evinces, that, at a trifling expense, I can secure Lord Ashburnham's estate from being inundated; for whenever the first hedge is not high enough to prevent the sea overflowing, another may be built upon the sand formed by that hedge, and so on in succession, till it is perfectly safe."

Even when a regular embankment is required against the sea, it is proper, a year or more before it is erected, to fix fascines of brushwood down in the clay, by strong palisades, in the line in which the bank is meant to be raised. By this line, the mud and vegetables, which would otherwise be washed away, are arrested, and a most valuable addition made to the soil.

In raising regular embankments to exclude the sea from low tracts of ground, it is necessary to distinguish between those cases in which the water only overflows during spring-tides, and those in which the land is covered every tide. In the one, the operation is easy; but in the other, attended with considerable difficulty.

When the land is only overflowed during spring-tides, there is time in the intervals, either to complete the embankment required, or to finish it in such a manner, that the flowing of the tide can do it no injury. But if the sea ebbs and flows every tide upon the land which is to be reclaimed, only small pieces of the work can be executed at a time, and the force of the water, at the flowing of each tide, is apt to destroy all that has been previously performed.

In either case, when only a part of the embankment can be executed before the return of the flood, it is proper that what is done should be done in a finished manner. Thus, supposing a length of thirty or forty feet, or yards, can be completed in one tide, it is better to raise it to its intended height, and to face the slopes well with turf, than to commence a greater extent of bank, and leave it in an unfinished state, exposed to the violence of the waves. It may be further remarked, that in low-flooded lands of the kind under notice, there are always several hollows or water-runs, formed by the regress of the tide; and where the embankment has to be executed in different portions, it may be proper to build in the first place, across the spaces between these water-runs, so that the sea, having its usual channels of evacuation left open, will have the less tendency to injure the work. The spaces, thus left unembanked, may be filled up during the intervals between spring-tides.

All the inconveniences, however, which arise from the interruption given by the sea to the progress of building embankments, may be effectually avoided by the following plan, devised and explained by Mr. J. Loudon, the ingenious author, compiler, and editor of many useful books:—

"Let triangular trusses of wood be prepared and placed at low water, surrounding a part of the foundation of the proposed embankment; the hypothenuse or sloping side of the trusses fronting the side all round, which side is next to be covered with boards, say about five feet broad, twenty long, composed of deals neatly joined; and one board is placed upright to prevent the spray from coming over; or, the trusses being placed and fixed upright by cross rafters, the whole may be laid over with single deals, without being closely joined, and then covered with oiled canvas or pitched sailcloth, neatly fastened on, and cemented at the joinings with a composition made of tar and clay; and this will be a more economical mode.

"The barrier being thus constructed and placed, it is evident, that as the tide flows, the water will surround it; and the higher it rises on it, provided it does not rise higher than fifteen or sixteen feet (about the general height of spring-tides), it will only press it down the more, and render it firmer than it would be, if only half of it were covered with water.

"If the embankment is to be made of clay or earth, or the same materials upon which it is founded, a space must be inclosed of sufficient width to allow these to be dug out from the land side of the bank; or if it is to be wholly built of stone, or any distant material, these may be laid down beside, or upon, the spot to be built on, before it is surrounded by the barrier.

"When the length of the wall contained within one of these enclosures is finished, the barrier must be moved along, so as to take in another space, which must be built upon as before. The barrier must then be again taken down and replaced, &c.; and so on, until the whole line of embankment is finished.

"The original expense of this barrier may be from £100 to £400, and it may be moved and replaced for twenty or thirty shillings each time; and as the wood of which it is made will generally be of considerable value after the bank is finished, the total expense of this barrier will not be so great as at first sight may be imagined.

"By means of this barrier, it is evident, that embankments may be made as far out as the sea retires; and even beyond that, buildings of any kind may be constructed within it, with ease and safety. The only additional expense, when the barrier was placed *among* water, would be that of pumping it out, which could easily be accomplished by a wind-mill, or any other such simple contrivance."

In some instances, where the sea overflows the piece of land to be reclaimed, to a great depth, a different mode of operation from any that has been described, has been adopted. The line of embankment being marked out by poles, quantities of stone and clay mixed, are conveyed in flat-bottomed boats or punts, and thrown overboard, until a bank is accumulated. This mode, it is believed, is common in Holland.

The materials of a proper bank, and the mode of constructing them, have already been explained. Its elevation and slope should depend upon the degree of exposure to the winds and tides, and the height to which the greatest tides are accustomed to rise. The elevation may vary from five to fifteen feet, and the front slope from twenty inches to five feet for every foot of height; the back slope being generally one half less than the other. In every case, the bank should be at least two feet higher than the water during the greatest spring-tides. In determining the slope, great care must be taken to proportion it to the force of the sea, as nothing can be more ruinous than to make the bank too bold or upright. It has been well remarked, that a wave which falls on a flat surface dies without a struggle, while one that is stemmed by an abrupt rock strikes with tenfold force. The evil of not estimating properly the force of the sea, is remarkably exemplified in the case of some extensive embankments at the mouth of the river Cree, in the county of Wigton. The banks on both sides of this river were made of the same dimensions, being about four feet and a half high, and nine feet broad in the base, without adverting, that the northern bank is exposed to the south-west winds, which in that quarter always bring up the highest tides. It happened, accordingly, that at the first high tide, the embankments on the northern side were almost totally destroyed, while only a few breaches were made on those of the southern. To have enabled the former to withstand the superior force which assailed them, the dimensions ought perhaps to have been double those of the latter.

Along the back of all sea-banks, trenches should be made in the same manner as in river embankments, and sluices erected at different parts, to shut of themselves against any external water, and to open when the tide ebbs, to let out any water from within.

In every case, where an external valve is required for the discharge of the surface-water of an embanked area, and where it is liable to be choked up with sand or gravel, as behind a shifting beach, or in front of the open sea, means must be taken to defend the valve from stoppage, or great attention be given to keep it clear. In some situations, the valve is so liable to be buried, and the channel closed up, by every spring-tide, or gale of wind, that the only effectual remedy is to make a covered channel through the line or ridge of the beach into the sea; and this must be made strong enough to sustain the weight of the heaviest breakers. This expedient has been adopted upon Lord Cawdor's estate in Pembrokeshire; and though found extremely expensive, yet the advantage gained is so great, as to render the undertaking profitable. In cases of less extremity, the valve might be sufficiently guarded by a pile fence or a pier, carried out from the foot of the embankment, across the known drift of the beach, the sand, which might accumulate behind this fence, being removed from time to time. Where the sea reaches to the foot of the embankment, it has been found necessary to erect two flood-gates, the one within to secure the outfall channel, and the other on the outside to ward off the waves, and prevent them injuring the inner works. The outer gate may in this case be lifted; but though a considerable quantity of water should be admitted, yet its force being broken, the inner valve will remain undisturbed.

It sometimes happens, that salt marshes, particularly those at the sides of estuaries, are situated so low as to lie constantly under water. In cases of this kind, the following mode of drainage and embankment, practised on a marsh near Marazion, in Cornwall, may with propriety be adopted.

The marsh in question was situated on the bank of a river, and separated from the sea by a tract of sand consisting of about seventeen acres. It lay always under two or three feet of water, and the sea flowed over it at spring-tides. As it was found impossible to take off all the surface-water by the river, a square wooden pipe of nine inches diameter was carried through below the tract of sand above mentioned, from the edge of the marsh to that part of the shore called *half-ebb*, which was eight feet lower than the surface of the marsh. At the mouth of this pipe, a reservoir, of 18 feet square and eight feet deep, was cut out, and from this reservoir a trench of three feet deep and five wide was extended on each side, between the sandy soil and the marsh. At the distance of every sixty yards, cuts were made from this main trench across the marsh, by which the whole area was divided into oblong square fields. By means of these trenches, all the surface-water was conveyed into the reservoir, and from the reservoir conducted by the pipe into the sea. At both extremities, the pipe was guarded by valves, which shut at the approach of the tide, and opened upon its regress, to let off the water which had collected in the interval; and before the valves, iron bars were also placed, to prevent the intrusion of extraneous bodies. When the surface-water of the marsh had been thus removed, a strong embankment of turf was erected on those sides of the marsh where it was exposed to the influx of the sea; and, by a judicious course of management, the ground became, in the course of a few seasons, covered with rich crops. The reporter remarks, that the whole of this improved ground, including the marsh, the sand tract next the sea, and a piece of croft or elevated ground behind the marsh, "has been productive of considerable advantages to the public, particularly to the poor. Four hundred persons yearly receive turf from it, two hundred and fifty are fed most plentifully with potatoes, which are planted here by very poor people, who are, in consequence of having land given them, become uncommonly industrious; and the whole neighborhood, by its drainage, have got rid of low nervous fevers and agues, with which it was commonly pestered."

The tracts of salt marshy ground, which have been reclaimed in Scotland, are not very numerous; but it is hoped the profit which these have afforded, may tend to induce further exertions in this branch of improvement. Perhaps there is no place in which more valuable acquisitions have been made in this manner, than in the island of Islay, under the direction of its intelligent proprietor, Mr. Campbell of Shawfield. At the head of an arm of the sea called Loch Gruinart, an embankment has been executed, by which four hundred acres of land, which formerly composed an useless salt marsh, have been brought under the plough. In making this embankment, it was found that a considerable stream, which discharged itself into the head of the loch, impeded the operation of the flood-gates; and, as the only effectual method of removing this serious inconvenience, Mr. Campbell had recourse to the expensive and arduous expedient of totally reversing the course of the stream, by withdrawing it from its old channel, and leading it through the opposite side of the country into Lochindaal. The whole of this embankment was executed in one summer. The total expense was about £600. The ground which was reclaimed was let at an additional rent of £235; so that, estimating this at thirty years purchase, the immediate gain by the embankment was £7050 sterling. Mr. Campbell has finished a similar embankment against the sea at the head of Lochindaal.

Along the shores of the Forth, some important acquisitions may also be noticed. "The whole tract of land," says the reporter of Stirlingshire, "which stretches along the Forth, appears evidently to have been covered, at some remote period, with the waters of the sea, which, gradually retiring, have left this soil the richest in Scotland, exposed and fit for the operations of agriculture. These carse lands are very little elevated above flood-mark; and all along the coast the frith is so shallow, that, at low water, many hundreds of acres are left dry, the soil of which, when recovered from the sea by embankments, is equally valuable with that which had been long under cultivation.

"The idea of recovering this fertile soil from the sea, seems to have been originally suggested by a Dutchman, about the beginning of the last century. In the parish of Borrowstounness, he proposed to acquire by this method a tract of two thousand acres, upon condition of his being allowed the possession of it for forty years, and timber from the woods of Kinneil necessary for erecting the dikes. The proposal was rejected. Had this proposal been accepted, it is evident, that, at the current rent for which such lands are now let, the proprietor might have enjoyed at this day an additional income of £10,000 a-year.

"The proprietors of the adjacent shores in Stirlingshire have at length awakened to a just sense of their interest in this important species of improvement. A considerable deal *has been done* in embanking, but much more *remains to be done*, in the parishes St. Ninian's, Airth, Bothkennar, and Falkirk."

The number of acres of carse soil lately recovered from the Frith of Forth in Stirlingshire alone, has been ascertained as follows, viz.

	Acres.
Reclaimed by Lord Dundas, - -	200
" by the Earl of Dunmore,	200
" by other proprietors, -	200
	600

Thus it appears, that within these few years, there have been recovered, in one district alone, by embankments against the sea, no less than six hundred acres of the richest soil in Scotland, now let at five guineas per acre.

On Lord Dandas's estate, five hundred acres more may be easily reclaimed in the same manner. The writer of this Treatise has inspected the ground, and seen the estimate of a respectable undertaker, which shows that the expense would not exceed £20 per acre. Thus the whole expense would amount to about £10,000; and the return, at the ordinary rent of £5 per acre, would be £2500 a-year, or about four year's purchase of the soil. Two hundred acres more of the same quality adjoining it, might be recovered at a similar expense.

On Lord Dundas's estates of Clackmannan and of Bambriech in Fife, a considerable extent of land has also been embanked from the overflowing of the rivers Forth and Tay, and is now let at £5 per acre. On the estate of Kincardine,* adjoining that of Clackmannan, similar successful embankments have been made; and it is proposed to extend these still farther into the channel of the Forth.

Besides the private emolument which would accrue to individuals from the spirited prosecution of these embankments, a very important public benefit would also arise. Were they completed, the navigation of the Forth and Carron would be greatly improved; the waters of the frith, which are now spread over a large surface, would be confined within a narrow channel; and the depth would be so much increased at full tide, as to admit vessels of a larger burden.

Wherever, on the other hand these embankments are neglected, the sea is gradually gaining upon the land, and washing off the most valuable soil; a striking instance of which has been observed to the north of the confluence of the Carron.

But there is reason to hope, that many years will not be allowed to pass, till, on the shores of Stirling, Linlithgowshire, and many others, there shall be added many thousand acres to the carse soil of Scotland.

The Duke of Hamilton, some years ago, engaged in the embankment of about 300 acres on the estate of Kinneil, near Borrowstounness; but after two years' trial the attempt failed. It is, however, perfectly practicable, if the proper plan were prosecuted, which it is hoped, the present enlightened proprietor will not hesitate to carry into effect.

It is a fact worthy of remark, that all along the shores of the Forth, the sleech has increased very much, and is increasing every year, by the accumulated deposition of moss brought down from Blair-Drummond, by the floating it away from that extensive tract, which has undergone so great improvement since the commencement of that operation by the late Lord Kames. This is one great inducement to the prosecution of that scheme of embankment, which is so practicable all along the course of that river. The land that has lately been embanked by Lord Dundas, (according to a plan, and under the direction of the author,) was, fifty years ago, covered to the depth of nearly thirty feet at high water, where the depth would not now have been more than five feet at the highest tides, owing to the gradual deposition of the floated moss.

The banks of the Clyde present, in the same manner, more striking instances of what may be done, than of actual improvement, by embankment. The following example deserves notice, as it shows both the facility and cheapness with which such works may be raised, and the petty interests which too often impede and defeat the best

* Belonging to the Countess Flahault.

schemes of improvement:—"From a charter granted to the burgh of Dumbarton, in the year 1609, it appears, that a great part of the lands belonging to the community had been recently overflowed by an inundation of the Clyde and Leven, and even the foundations of many houses and gardens overturned. No less than 37,000 merks Scots (a large sum in those days) is granted "for the purpose of erecting *dikes* or *bulwarks*, to confine the river Leven within its old bounds." Though vestiges of a mound of large stones are still discernible, and afford proof that some attempt was made to reclaim the land thus lost, the attempt appears to have been unsuccessful. The whole common, extending to about two hundred acres, is often nearly overflowed. Even the highest part of it is insulated every tide, and the remainder consists of bare sand, covered with water twice a-day. The only use to which it is put, is pasturing a few cows belonging to burgesses, with which it is at all times greatly overstocked, yielding a trifle to the town's treasury, and not much profit to individuals. About the year 1788, Mr. Whitworth the engineer, who superintended the finishing of the Forth and Clyde Canal, was employed to survey this piece of ground, with a view to its being embanked. He accordingly made out a profile of the embankment necessary, with an estimate of the expense; which, after making an ample allowance for unforeseen accidents, did not exceed £1400. This would have amounted to no more £7 for each acre; but though it should have cost double that sum, it would have been a trifling price for such excellent land, created, as it would in a great measure have been, by this operation. The plan, however, has not been carried into execution, owing probably to the narrow revenue of the burgh, and the difficulty of satisfying the claims, and reconciling the competing interests of the burgesses, many of whom would not readily consent to relinquish their ancient right of pasturage, or exchange the insignificant profit derived from it, for the contingent benefit resulting from the melioration of the common on which it is exercised. It is scarcely probable that it will be set about in earnest, till a recurrence of violent floods and high tides, which former experience has shown to be not impossible, shall endanger the existence of the town, and compel the inhabitants to unite in this work as a measure of self-preservation."

The last branch of sea embanking, of which it is necessary to take notice, is that for recovering tracts of land, unnecessarily occupied at the estuaries or mouths of rivers. In consequence of the regorging action of the sea, all streams spread greatly at their mouths, and the earth they bring down is deposited there, and accumulates into shoals and islets. The soil which is thus formed, is invariably of the richest kind, and the recovery of it becomes of course an object of proportional advantage.

The most advisable and effectual plan for this purpose, when it can be executed at a remunerating expense, is to alter the course of the river altogether, and make it discharge itself at some new point of the coast, where the land that would be occupied by its channel, might be of less value, and its discharge less exposed to be choked or shifted by the regorging action of the tide. Where this has been done, it has been found, that the old channel, in the course of a few years, was filled up, and the sea quite excluded. If such a complete change cannot however be effected, the whole river should be collected into one stream, the channel should be deepened, to make the water flow with celerity; and embankments should be raised on each side, to prevent it from spreading in future, over a space that may be converted into useful land.

PART II.

EMBANKMENT ON RIVERS.

SECTION I.

On protecting land from the encroachment of rivers, by defending and securing their banks, &c.

A river that flows in a confined channel, is apt to commit ravages on adjoining land, by the continued action of the stream gradually breaking down, and carrying away the banks, where they are of a soft, loose, and friable or penetrable nature. The danger of the soil being carried away in floods, is increased or diminished, according to circumstances; such as the form of the banks; the nature of the soil; the rapidity of the current; and the quantity of water that, after floods, lodges on the margin of the banks, or falls over them into the river.

When the banks of a river are perpendicular, or nearly so, if the soil be of a sandy or mouldering quality, the danger of their being washed down and carried away by floods, is greater than where they slope gently, from the surface of the field to the bed of the river. But, if the soil and sub-soil be of a clayey or adhesive loam, and the current presses equally, and not more upon one part than upon another, a simple and efficacious improvement may be made, by sloping the bank so, that it forms an easy declivity, from the surface of the field to the bed of the stream. This slope soon becomes closely coated with grass, and the water, by gliding gently along, is in no danger of making a breach or encroachmeent at in any part of it.

As a proof of this, it always appears, that wherever there is a gradual slope upon the bank of the river, and the grass growing upon it naturally, that the greatest flood makes no impression, nor does it any injury; as the water passes over it gently; and, not being confined or opposed, has room to expand. On the contrary, when it comes against a ragged or abrupt bank of earth, it soon undermines, and brings it down in great quantities. This is so obvious to the slightest observer, that it is astonishing so simple and easy a remedy should not be resorted to, in all cases where the banks are of this last description.

A stream of water having naturally a greater inclination to recede from, than to surmount the obstacles it meets, it always takes an angular or serpentine course; and it is in consequence of the river thus dashing from side to side, that injury is done to the banks. Were a river to flow in a straight line, or nearly so, which it would invariably do, if not interrupted, it would make no encroachment on its banks.

The most effectual remedy, in such cases, must, therefore, be to *straighten the course of the stream.*

This is an operation, which, in respect of natural circumstance, might in many cases be performed with little difficulty and expense; and, where most essential, usually with the greatest facility. But the smallest improvement of this kind, is in general rendered impracticable by minute divisions of property, and other attendant causes. A river is considered to be so far a common subject, that while a proprietor is entitled to take every natural advantage of the stream in passing, he is interdicted from executing any operation upon it, which can prove injurious to the other individuals who possess lands upon its banks. For example, if by ponds or dams, he throws back the water upon a superior property; or by juttees, directs its strength upon the opposite bank; or by straightening the channel, makes the river rush with more than usual violence upon the inferior lands: he will commit an injury in each case, of which his neighbor has a right to complain. There is, in fact, in every situation, such a collision of interests, that it is seldom possible to reconcile them to any extraordinary alteration on a river; and above all, in so *direct* and *radical* a one as that of straightening the channel.

The case in which this measure may be recommended as most expedient, is that of those mountain streams which intersect the haughs, or hollows between the different ranges of hills or high lands. All these haughs are composed of soil of the richest kind, formed of particles of earth washed down from the heights; and thus are the most valuable portions of land, both in the low country and in the highlands. But, in consequence of the streams that intersect them being allowed to roam at pleasure, a great portion of soil is, in such instances, unnecessarily lost; and what remains is so constantly liable to be broken up and destroyed, that the produce of haugh lands rests altogether upon a most precarious tenure. To explain these facts, it may be remarked, that when a stream is permitted to *wander at will* through such hollows, it occupies, by its devious course, four or five times the quantity of ground which it would do, if carried in a straight line; that, in consequence of the angular outline of the banks, the water strikes against them with violence, and continually makes encroachments; and that, by the circuitous direction of the stream, and the turbulence which that occasions, the evil effects of every flood are greatly increased.

The advantages of straightening such a stream are, accordingly—1. That a great addition of valuable soil will be obtained; 2. That the stream will be rendered more placid; less capable of doing injury to the banks; and less extensive in its inundations, and in its ravages.

The execution of the operation is moreover much easier in this than in other cases. The streams which takes their course through haugh lands, are in general nearly exhausted, sometimes enirely so, during the summer months; so that an alteration of the channel at that period of the year may be accomplished with comparative facility. And further, the soil, as well as substratum of haugh lands, consists generally of loose and incohesive materials, which are easily dug out and removed.

The great object, in improving the course of a haugh stream, should be, to lead it as straight forward as possible. If the haugh be winding, or there be obstructions, which prevent a cut from being made in a straight line from the entrance to the outfall, the stream should be led from to side of the haugh in straight reaches; always endeavoring to make some prominent rock, or point of sufficient firmness to resist the current, the vertex of each angle; or, where such cannot be found, raising an artificial bulwark of stones in its place; it may be led along the foot of the bank all the way, by which means the haugh will be kept entire, and the natural bank will be a barrier on the one side; and the earth thrown out of the cut, will be sufficient to form an embankment on the other, and to fill up the old channel also.

When a new channel is designed to be cut, its breadth may be less than that of the old, while its depth ought to be greater; because the narrower and deeper a channel is, the water always flows with greater ease and regularity. The lines of the intended banks being marked out, the earth should first be dug out from the middle of the inclosed space, to the full depth proposed; and on each side, the depth of the excavation should be gradually lessened, so as to form a convex slope to the tops of the banks, this form being of all others the best fitted for diminishing the pressure of the water, either in ordinary or extraordinary floods.

To secure the new banks against the action of the stream, they should be carefully faced with stones or turf. The former compose the best defence, and may, in most cases be employed; as abundance of stones is generally to be found on the banks of mountain streams. At the bottom of the facing, the stones should be of the largest sort, and sunk well into the ground, to prevent the water from undermining them. In carrying up the rest of the wall, the stones should be laid *endways; i. e.* their inner ends pointing to the same centre like the stones of an arch, and earth or gravel should be rammed firmly in behind, as the work proceeds. Between the stone-work and the green sward on the top of the bank, there should be several layers of thick tough sods or turf, which will not only serve to bind the stones, but make the junction of work with the natural bank smooth and compact. When the whole facing is executed, the stones and sods should be forcibly beaten into the bank with mallets and rammers, in order to make it more firm and secure. If any fissures still appear, long splinters of stone should be driven in, which will not only fill up the vacant spaces, but act as wedges to fasten and consolidate the rest of the work. When sods are employed to make the facing instead of stones, the foundation ought at all events to be defended by large stones; and it may also be proper to drive a single or double line of stakes into the bank to prevent the current from tearing away the sods, or even disarranging the stones.

In the case either of stone or turf facings, it has been found useful to scatter a quantity of coarse hay seeds over them; as they vegetate quickly, and tend greatly to fasten the work The firmness of the bank may also be considerably increased, by setting willows or other aquatic plants along the top. *

The most difficult branch of the whole operation, is that of leading the stream out of the old

*These should never be allowed to grow up as trees; but be cut over occasionally, so as their roots may spread, and they may not be shaken and affected by the wind.

into the new channel. When the mouth of the new cut can be made to fall in with a bend of the old channel, the change may be made with comparative ease, as the current will flow into the new channel in a straight line. In this case, the materials dug out in forming the mouth of the new cut, may be sufficient, when thrown across the old stream, to turn its course. But if the alteration of the channel be abrupt, and the stream strong, it will be requisite to raise a pier of stone upon the bank of the old channel, to direct the current forward to the new one: a water-tight dam being formed between the point of the pier and the new bank.

The materials dug out from the new channel may either be employed in filling up the old one, and thus facilitating its future conversion into arable or pasture land; or if the stream be liable to high floods, they may be used in erecting embankments on each side of the new channel.

In the case of *vale* rivers,* the expedient of straightening the channel is equally advisable, though not so easily practicable, as it is upon *alpine* streams. In the latter case, a cut three or four feet deep may frequently suffice, and stones for erecting piers, and facing the banks, are found in abundance; while in the former, a depth of from six to twelve feet is sometimes necessary, and stones are not obtained without considerable difficulty, There may, nevertheless, often be situations where the extent of ground to be acquired by a new cut through a valley, will amply repay every expense and trouble attending the operation.

Of many similar instances, the following is one, where nearly 1000 acres have been secured in this way, at a very trifling expense; and, as a particular description of it may be useful, in directing the execution of operations of the same kind, it is given at length. In the parish of Kilsyth, Stirlingshire, the river has its course, for upwards of four miles, over a plain of small declivity, and of a soft loamy soil. It formerly straggled in many directions over this plain, in a channel of very little depth. At every turn it took, it was gorged up into a pool, and was overgrown with aquatic vegetables. At every flood, the whole valley presented the appearance of a lake; the hay and corn harvests were frequently ruined; and several fields, naturally of a rich soil, were rendered incapable of cultivation.

About the year 1793, Sir Archibald Edmonstone, of Duntreath, Bart. who was proprietor of the lands on the north side of the river, for more than four miles, employed Mr. Whitworth, an eminent engineer, to form the plan of a new cut sufficient at all times to contain the waters of the river, and as nearly in a straight line as the situation of the grounds and the course of the river would admit. To induce the proprietors on the south side to join in this useful undertaking, he generously offered to lay out two-thirds of the expense himself. So slow, however, are persons of unenlightened minds in discerning their own interest, that only a few of them, at that period, acceded to these advantageous terms. During the first year, only about a mile and three quarters of the new cut were executed. But the advantages of this partial improvement soon become so obvious, that the greatest part of the conterminous heritors concurred with Sir Archibald, in prosecuting the plan, though not altogether upon such liberal terms, as a just sense of their own interest might have dictated. Early in the course of the second year, the cut was completed.

The dimensions of this cut were varied judiciously, according to the gradual increment which the river receives in its course. For the *first* mile from above, where the river is of considerable extent, it is from eighteen to twenty feet wide at the surface, by ten to twelve at the bottom. Throughout the second mile, it is from twenty-two to twenty-four feet wide at the surface, by fourteen or sixteen at the bottom. Throughout the the remaining part, it is about twenty-eight feet at the surface, by sixteen to eighteen at the bottom.

The first part of this cut was undertaken by the contractor at two-pence per cubic yard; but he was only bound to lay down the earth regularly at the distance of a yard from the cut, without any obligation to form it into a regular sloping bank. It was understood that the conterminous heritors would execute this part of the operation. As they, however, proved negligent in this respect, it was found necessary to enlarge the contract; and two-pence farthing per cubic yard was allowed for cutting, and for forming the bank. The low rate at which this contract was entered into, may be accounted for at this day, not merely from the facility of working in a rich loam or clay, but chiefly from the well-known, and by many severely-felt, depreciation of money at that period. Such a work would not probably be now undertaken for less than fourpence per cubic yard. The expense of the whole of this cut did not exceed £600.

The embankment on the sides of the cut is erected about three feet from the brink, and is, for the most part, somewhat more than three feet in height; and could contain nearly double the quantity of water than now runs in the new channel.

The improvement, which has been now described, has been productive of very important advantages in this naturally fertile district. The declivity or fall of the river, throughout the tract, is about eighteen feet. The waters which formerly, in their crooked course, were almost wholly stagnated, now run at the ordinary rate of the declivity which is given them. They never overflow their banks. Cattle can now pasture upon those grounds, in which they would have formerly been swamped. The surface of the water being now, for the most part, four, and sometimes six feet below that of the adjacent fields, this cut serves as a general drain to the whole valley; so that three hundred acres of meadow may be converted into arable land; sixty acres of moss may be converted into meadow; and five hundred acres of arable land are already rendered of double value.

If the windings of a river cannot be altered, either from natural obstacles, or from the opposing interests of proprietors—or if the expense of the alteration be such as to render it unprofitable—it becomes the duty of proprietors then to consider, how far the subsisting channel can be improved, so as to lessen the ravages of the stream; or what means can be adopted for guarding their own lands, without injuring those of their neighbors.

As the impediments a river meets are the cause

* Those flowing through holms, haughs, or meadows, in the *low country*.

of its being turbulent, the first and most obvious thing to be done, is to remove all heaps of mud, stones, trees, or bushes, which are collected in the channel, and obstruct the course of the water.

At those places where the river encroaches, the means which may be used to defend the banks are various. In some instances, bulwarks of stone, laid regularly in wooden frames, have been raised: but though such wooden frames facilitate the construction of the work, they prove ultimately injurious to it; for in consequence of being alternately wet and dry, they soon rot and give way, leaving wide gaps, through which the water enters, and breaks up the embankment. In some places, large sloping cairns, or structures of loose stones, have been employed: but where the extent of the bank to be defended is great, or timber scarce, such a bulwark is expensive, while it is at best only temporary.

Another method has been recommended by Dr. Walker, in his 'Economical History of the Hebrides,' as preferable to either of these:—"Form a single or double line of stakes in the bed, or on the bank of the river, of the branches of trees. These stakes may be from the thickness of one's wrist to that of man's leg: they are to be driven into the soil between two and four feet deep, and reach above the ground, or above the water a little higher than the rise of the greatest flood. They may be from six to twelve inches distant from each other; and if there is a double row, they are to be placed in the quincunx order.

"Such stakes, thus situated, can neither be displaced nor shaken by any force of water. They stop and entangle every sort of refuse brought down by the river. They intercept the mud and the gravel, which gradually form a bank, and force the river to establish a barrier against its own incursions—a barrier likewise far more efficacious and more permanent, than any that can be formed by art, with earth and stones.

"It is an obvious property of this mode of defence against the encroachments of rivers, that it is easily and quickly executed, and at a mere trifle of expense. A single cart load of such stakes, in some situations, might effectually preserve many acres of rich land. Every river, by the above method, may be thus turned and directed in its course at will. It would always be advantageous, if the stakes employed in this way were of the different sorts of willows.

"These take root, grow, and form a strong living fence against the river. But if stakes of willows cannot be provided, cuttings, or truncheons of willows, ought to be sunk in along with the stakes, and intermixed with them.

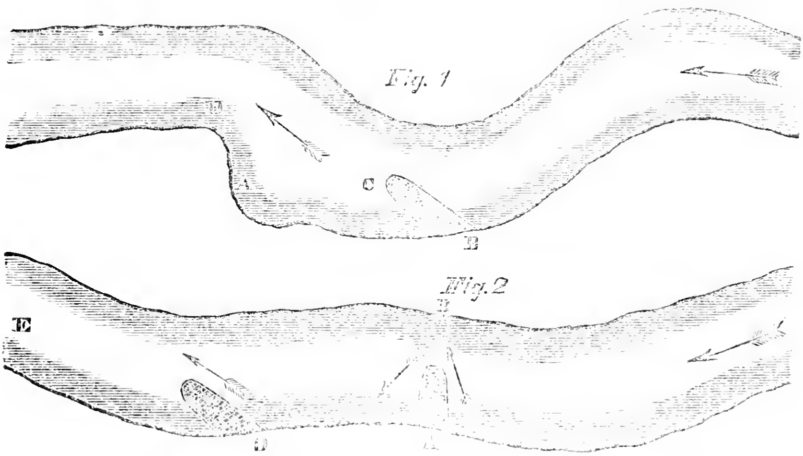
"For which purpose, the shrubby and low-growing willows are more proper than the most willow, the osier, the crack willow, or any others which grow up to a tree."

This mode of defence is judicious; but the difficulty of executing it in a proper manner, may perhaps exclude it from general adoption. To enable the piles to withstand the force of the river, they must be sunk a greater depth into the ground than it is possible for any mallet to drive them. Dr. Walker mentions from two to four feet of depth as sufficient; but from the experience of others, it appears, that at least eight or nine feet is necessary, to render the piles firm; and to this depth they cannot be driven by any thing else than a pile engine, which in many situations it is difficult, and in all circumstances expensive, to procure. The inability of mallets to drive the piles, was particularly shown by the experiments of Mr. Miller of Dalswinton, upon the river Nith, in Dumfries-shire. In order to prevent the encroachment of this river upon part of his property, he drove in a number of piles at a little distance from the bank, and wattled them with the branches of willows, &c. The piles were driven with heavy mallets apparently firm into the ground; they continued so for some months, till a heavy fall of rain having swelled the river, the piles were undermined and carried away.

When there is an opportunity of executing a bulwark of piles properly, the method adopted by Mr. Miller, of wattling them with willows, &c. will be extremely useful in intercepting the mud and refuse brought down by the stream.

A more easy and effectual device, than any which has yet been mentioned, for defending the banks of a river, is that of stone piers or juttees. The object of these is, to throw off the stream from those places on which it threatens to make encroachments, to others where it can commit no injury. Thus, if a river be encroaching on one its banks at A, Fig. 1, of Plate II. a jutty of

PLATE II. *Plan representing Juttees for the defence of River Banks.*



stone, a little way up the river, in the direction B C, will direct the current towards D, and prevent any farther injury.

A jut y of this kind ought to be carried out in an oblique direction, so as to force the current gradually towards the intended point. If formed too much at right angles with the stream, as at A. Fig. 2, it will throw the stream with violence on the opposite bank, at B, from which it will revert with double force upon C, the place immediately below the pier; so that, instead of diminishing, it would increase the destructive effects of the stream. But, if the jutty is placed obliquely as at D, it will force the current gradually towards E; in which position, one jutty may do more good, than several placed improperly at right angles. It may be further remarked, that when a pier is abruptly intruded into the natural channel, it requires from five to ten times more strength of structure than one which deviates gradually from the direction of the stream: in the one case, there is both the weight and force of the water, while in the other there is merely its weight, to withstand. And, above all, it is important to consider, that by making the pier in the direction prescribed, it cannot occasion any injury to the opposite bank.

The materials for constructing a guide of this nature, depend upon the magnitude of the stream to be directed. If it be small, a ridge of stones thrown loosely in may suffice; a barrier of this sort is both cheap and effectual, and when injured by any extraordinary flood, is easily repaired. When the land through which it passes is very valuable, and in the vicinity of a town, and the river is large and rapid, so that a pier of considerable height is necessary, it is proper if the expense be not excessive, to construct the pier of stone and mortar. In other situations, where masonry is too expensive, and the ground of less value, it may serve the purpose to employ casoons formed with piles and planks, or strong cases of wicker-work, and either of these filled with small stones or gravel, in order to give them stability; and they should be sunk along the edge of the banks, in as regular and firm a position as possible. These last expedients have been practised most successfully on several parts of the river Spey, and at Careston, on the banks of the river South Esk, in Forfarshire.

As the Spey is one of the most rapid and impetuous rivers in Scotland, and as the methods of embanking it is have been various and expensive, the following description of these operations, in its course through the Park of Gordon Castle, where it most ungovernable, may be useful in similar cases, and is given from the 'Agricultural Survey of the County of Banff.'

"It is believed, that the Spey first began to make encroachments on the skirts of the Park of Gordon Castle in September 1768, by the violence of the highest flood which tradition has kept on record. The first kind of embankments which were thereupon attempted, were expensive bulwarks of stone, built by the mason, but without motar. Their appearance, indeed, bespoke both efficiency and duration; but, like other fair appearances, "*it smiled deceitful;*" and, notwithstanding the continuance of expensive operations, the river, frequently levelling the works, maintained the contest with sucess, and on the whole, gained ground, when the opposing power was placed under the direction of the late Mr. Smeaton, who, on a brief survey, disapproved of all the costly bulwarks, and directed nothing more expensive than mounds of stone, loosely thrown together, almost at random, from the bed of the river, with no other art than to be raised higher than the water could, at any time, surpass, and to form a sloping shore, shelving back from the channel of the river. The embankments constructed on this principle, have been, almost to a wish, successful. The river, now is, as it were, entirely subdued; and the highest floods, although their violence in a thaw be exasperated by heavy masses of floating ice, hasten harmlessly along, dashing onwards directly into the sea.

"On some occasions there has been a departure in practice from Mr. Smeaton's theory, by forming a kind of mole of stakes, in collateral rows, to the breadth of four or six feet, driven firm into the gravel by the powerful repeated strokes of an appropriate engine. The stakes were bound together near the top by transverse bars, and supported by stones thrown in to fill up nearly all the vacuities. This kind of embankment was more expensive than the former, although the timber was furnished without price from the forest on the other side of the Park; and it was less efficient, because, instead of diminishing the power of the stream upon the gradual shelving of the slope, it was increased by direct accumulation against the perpendicular side of the mole; and, instead of adding any depositions of gravel, and turning the channel thereby to a greater distance from the shore, the torrent was brought to bear harder on the pile, and any gravel which had been left there before was swept bare off. The ordinary bed of the river was established along the course of this kind of pier; and it somehow not admitting easily of repair, brought the case into a worse state, almost, than it had been before.

"To render this kind of mole efficient, therefore, it would be necessary to add also the shelving slope of stone along the base of the pile, forming that gradually rising shore, which the river itself, on some occasions, exhibits, and which no power of the flood thenceforth ever injures; as if nature would thereby teach us the only secure mode of guarding against the robberies of the torrent." *

When the pier consists of masonry, it has been found prudent to throw in a number of large rough stones against the foundation, in order to prevent the stream from undermining it. Opposite to the head and outer point of the piers, piles should also be driven into the channel, to break the force of the water, and secure these important parts of the work from dilapidation.

There is another evil that piers are exposed to during floods, of which it is proper also to take notice. When the river surmounts the pier, the body of water which falls over, naturally scoops out a pit in the ground behind, and undermines the precipice over which it tumbles. This evil may be wholly removed, by raising the pier so high as to prevent any overfall; but this is a remedy too extreme to be often advisable. The most

* The author inspected these embankmets, and reported his opinion of several improvements, to the late Duke of Gordon, when making a survey for the drainage of the Huntly Estate, in 1811.

prudent plan is to endeavor to break the strength of the fall, or to shield the ground from its violence. For the former purpose, the back part of the pier may be made with a shelving or flatly inclining surface; for the latter, a strong convex floor paved with stone, may be made behind the pier, to receive the fall of the water. Of the efficacy of this last method, Mr. Marshall gives a strong example. * "Some ten or twelve years ago," he says, "finding that the foundation of a sea-wall, (or strong stone-facing against a wide open estuary), over which a large body of water, in times of floods, falls six or eight feet perpendicular, was constantly under repair, though every known expedient had been used to counteract the effect, I directed a convex floor nearly in the form of a shield, to be laid with strong rough stones, edgeway, its margins being secured with the largest stones, as butments to the arch; the broad end of the shield buts against the foundation of the wall, and receives the water on its stongest part, the point gently declining to lead off the water smoothly into the sea. It still remains perfectly firm; perhaps, indeed, firmer than when it was first put down." This is a case, where, its being a protection from the sea, it required more particular strength, and consequently would be more expensive, than what is necessary in the case of rivers.

The expedient of juttees, which has been already explained, is certainly preferable to any other mode of defending the banks of a rapid river, both in point of ease and efficacy, and deserves to be more generally adopted than it is. A strong instance of its superiority occurred in the case of the river Nith, formerly mentioned. After the piles which Mr. Miller raised had failed, he resorted to the use of juttees, and found them to succeed completely. Those which he has erected have a convexical slope on the side next the current, in order to diminish the pressure of the water, and strong planks are also firmly set on edge among the stones, their ends pointed towards the river; so that to commit the smallest injury; the stream must move the whole body of stones on the line of each plank.

Where a river flows slowly, and its banks are of a soft earthy nature, the mode of resisting encroachments should be different from, and will be less expensive than, any which has yet been mentioned. Let a large quantity of the smallest branches of trees, of broom, whins, brambles, or such-like brush-wood, be placed in the river, near the side where it threatens to encroach. If the river runs slow, they require merely to be thrown in; but, if its current is considerable, they must be stuck into the bottom, and fastened with stakes driven through them into the sides of the bank. This heap of rubbish intercepts the slime and mud of the river, which quickly accumulates towards the bank, and becomes a most effectual defence against any further encroachment in that quarter.

Such are the principal methods that have been successfully employed for protecting and securing the banks of rivers in Scotland, and which the writer has had an opportunity of observing. There may be other expedients; but these being of less efficacy, and only temporary in their duration, it is unnecessary either to describe, or recommend them to practice.

* On Landed Property.

SECTION II.

On the embankment of low ground on the side of rivers, to prevent inundation.

In those wide and extensive regions that lie under a warm climate, the rivers are generally *periodical* in their inundations, from the rains falling only at certain periods of the year; and the regularity of the floods is greater, in proportion as the rivers are extensive in their course. Thus the Nile, the Niger, the Pegu, the Ganges, the Euphrates, and the Plata, are distinguished for their regular and annual floods.

In these cases, an inundation, instead of spreading ruin in its progress, is the source of extraordinary benefit. The mud and slime which it deposits, form a regular supply of the richest manure. The soil is raised to the highest degree of fertility; and being constantly recruited, can never be exhausted. The inhabitants, too, being always aware of the precise time at which the inundation will take place, have it in their power to provide against its doing injury, and to prepare the ground for receiving the nutriment with which the water is stored.

But in countries like Britain, which are narrow in extent, overspread with mountains, and exposed to a variable and humid climate, the rivers are short in their progress, and liable to be *suddenly* swollen. A flood, then, invariably commits wide and severe ravages. Sometimes it entirely strips the land of its vegetable soil; at others, covers it with a thick bed of sand and gravel. Not unfrequently the water loses its usual course, and cuts a new channel through rich and cultivated fields; and the most disastrous scene of all, is to behold valuable crops, and sometimes herds of cattle, swept off by the flood, thus graphically described by the poet of 'The Seasons:'—

> "Wide o'er the brim, with many a torrent swell'd,
> And the mixed ruin of its banks o'erspread,
> At last the rous'd-up river pours along;
> Resistless, roaring, dreadful, down it comes,
> From the rude mountain, and the mossy wild,
> Tumbling through rocks abrupt, and sounding far;
> Then o'er the sanded valley floating spreads,
> Calm, sluggish, silent."*

The flat *haughs* (as they are called in Scotland), or low ground, lying on the sides of rivers, and particularly near their entrance into the sea, are, for the most part, composed of the richest and most fertilized particles of earth, brought down by the stream from the adjacent country, through which it flows. These, from their situation, are often exposed to devastation, by their banks being encroached upon, and carried away in time of floods, whereby a portion of valuable soil is lost, and a bank of sand or gravel lodged on the opposite side, in its stead. But, besides the gradual injury which the adjoining land sustains (which

* In a highly embellished book, published by Sir Thomas Dick Lauder, Bart. an interesting, faithful, and picturesque account is given of the *great floods* occasioned by the overflowing of the river Spey, and others, in the counties of Moray, Nairn, Banff, &c. in 1829, which, in their melancholy consequences, confirm the justness of the above poetical quotation, the author being well acquainted with the different localities which Sir Thomas so forcibly describes.

is, in many situations, of considerable extent), from this operation of the current on the edge of the banks, (as has been explained in section 1.), the surface of the whole fields, thus situated, is exposed to inundation, when the river is swollen by the rain, and the torrents which descend from the neighboring heights: often sweeping away the crop, and deteriorating the soil, by the lodging of sand and gravel at one place, and the carrying away the mould at another. A sudden and rapid flood has also the effect of changing the course of a river; making it abandon the old, and take a new channel, through part of the ground, perhaps more valuable, by its being better cultivated, and on that account more loose, and easily acted upon by the current. In this case, the loss is aggravated, by the old channel being left a useless waste, in addition to the space occupied by the new course which the water has taken.

Accounts of havoc, committed by such inundations, abound in all the county reports, and imperiously enforce the necessity of adopting measures to prevent them. From the following detail of the evils committed in one district, a judgment may be formed of the general loss sustained by the country at large:—"The haughs of Isla," says the surveyor of Perthshire, "from Ruthven bank to the mouth of that river, a distance of ten miles, are exposed to inundations which are great and destructive. In the glens lying north of the Stormont, floods do great havoc among the hay and other crops. In Athol, at Bun-rannoch, in Glendochart and Glenlochy, torrents from the mountains swell the rivers so suddenly, that they spread far and wide, in many places beyond their banks, and frequently sweep off almost the whole labors of the year. The Tay and the Earn, the Devon, the Allan, and almost every river within low banks, which takes its course through flat land, brings desolation on the finest fields, which lie on its sides."

In the northern counties of Scotland, inundations are not so frequent as in the southern. The reason is, that where a channel is rocky, which is the case with most of the highland rivers, it is generally deep, and the river seldom overflows its banks; but where the intersected strata is of a soft and gravelly kind, and the expanse of the flat or haugh-land of greater extent, as in the low country, the channel is invariably shallow, quickly filled, and soon overflowed.

The manner in which inundations proceed, deserves particular attention, because, from observing this, we will be the better able to discover the proper remedy. "When a river swells," says the learned Buffon, "its celerity uniformly increases, till it begins to overflow the banks. From that moment its rapidity is checked, which is the reason why inundations always continue several days; for, though the quantity of water should be diminished after the commencement of the inundation, it would, notwithsanding, continue to overflow; because this circumstance depends more on the celerity than the quantity of water. If it were otherwise, rivers would often overflow their banks for an hour or two, and then retire to their channels, which never does happen. An inundation, on the contrary, always lasts some days, supposing the rains have ceased; and less water runs in the river, because the overflowing of waters diminishes their celerity; and, consequently, although the same quantity of water arrives not in the same time as formerly, the effect is the same as if a larger quantity had been brought down."

Farther, it may be observed on the motion of water, that, mathematically speaking, if a river runs on a bottom having an equal descent, the velocity of the water will increase, the farther it runs. Thus, suppose the descent to be one foot per mile, after the first mile the water will have acquired a velocity of eight feet per second; after four miles, its velocity would be sixteen feet per second; and at the end of sixteen miles, it would run at the rate of thirty-two feet per second—its velocity at every point being the same proportionally, as would be acquired by a body falling the same perpendicular height. These rules, with regard to the motion of rivers, cannot however be so accurately observed, on account of the perpetual obstruction the water meets with against the sides and bottom of the channel it flows in, which counteracts the power of gravity, and reduces the water to an uniform motion, where the declivity of the bottom and sides are regular. Supposing a given quantity of water is to be carried off, the smaller the descent, the width and depth, or section of the river, must be the greater; for the water, running in a large body, and slower, meets with a less proportional obstruction from the sides and bottom. Also, supposing the same quantity to be discharged, the larger the body it runs in, and the slower the motion, the more liable its course is to be obstructed by stones, mud, weeds, &c.

Large and deep rivers run *sufficiently* swift, and discharge vast quantities of water, with a descent of one foot per mile.

Small rivers and *large burns* require about two feet per mile. *Small burns* scarcely keep a free course under four feet per mile.

When a cut or channel, therefore, is to be made for a river or stream of water, through a tract of level ground, it is preferable to make it deeper at the lower extremity, in order to give a greater descent upon the bottom all the way, than to make a broad and less deep channel all the way upon a less descent; for the former method is attended with less expense of digging, and is better calculated to keep an open course.

From this explanation, it is obvious that the leading principle of all operations, to prevent a river from overflowing, should be *to increase and preserve its celerity.*

For this purpose, it may be first observed, that it is much better to deepen than to widen a channel. A contrary advice is given by some writers,* but, it is apprehended, without a sufficient attention to circumstances. If a river were always equally full, there can be no doubt that to widen its channel would prove a most effectual method to confine it within its banks. But as the quantity of water is constantly fluctuating, the widening of the channel would produce the following bad effects:—1. That when the stream happened to be small, it would scoop out a winding bed for itself in the middle of the channel; and upon swelling, would follow the direction of this bed, and thereby strike with violence against the banks. 2. That by lessening the depth of the river, its celerity would be diminished, and its liability to overflow of course increased; for it is an established fact,

* Beatson, Marshall, &c.

that celerity depends less upon the declivity of the channel than upon the weight of water. The importance of this objection is confirmed by this remarkable fact, that when once a river acquires a great celerity, it will both preserve it while running through a level country, and even surmount heights without spreading much to a side, or, at least, without producing any inundation of any moment.* 3. That by diminishing the celerity of the river, it would be more liable to be warped and impeded, as a greater quantity of *sulliage*† would thus be deposited in the channel.

At the same time, a caution must be given against carrying the principle here laid down to an extreme. It is as ineffectual to confine a river within too narrow bounds, as it is to give it too large an expanse. The width of the channel, therefore, should be such as will admit the water to flow freely, and maintain a *proper* or *safe* velocity.

To deepen the channel of a river, all the means which have been recommended for defending banks from encroachments—the removal of obstructions, and the erection of bulwarks to prevent the stream from spreading—will be found extremely conducive. In some instances, these operations may even preclude the necessity of embanking.

Where rivers flow through a very flat country, and their current is consequently less rapid, their overflowing, instead of being destructive, often produces beneficial effects, by depositing mud and other rich sediment, which tends to fertilize the soil in a very high degree. Where this is the case, embankment has a double advantage; for by means of sluices, a portion of the water can be admitted at the upper side, and retained at pleasure, by which means the influence of its effects can be regulated as circumstances require. Those large rivers that flow through valleys of wide expanse, have always a lengthened and crooked course, occasioned by the frequent changes that take place, by floods acting against the soil of which the low ground is composed. To make new and straight channels for such rivers, would be the most effectual improvement; but this, in many cases, would be attended with an expense much greater than the advantages to be gained. In others, however, it would be advisable to straighten such parts as are *very* crooked, and where the length of cutting would be short, and the expense moderate. By this means, the length of embankment would be shortened, and kept in a straight line, which is a great desideratum. Indeed, the line of embankment should be kept as straight as possible, even if the course of the river be crooked; for it is against the bends and turns that the water has greatest weight, and is most apt to burst through the bank. The loss of this ground, by its being excluded from culture, is counterbalanced by the security which it provides, in giving the water more room, and consequently lessening its force and pressure; and though not accessible to the plough, is valuable as meadow or pasture. The annexed plan, No. III. will further explain these positions.

In all smaller streams, or *burns** (as they are called in Scotland), straightening, widening, and deepening the channel, is the first and greatest improvement; and, in many cases, these operations alone may be sufficient to confine the whole body of water in a flood, and so render any embankment or further defence unnecessary. If the capacity of the channel is not sufficiently enlarged by these means, the width between the embankments will require to be the greater, and their

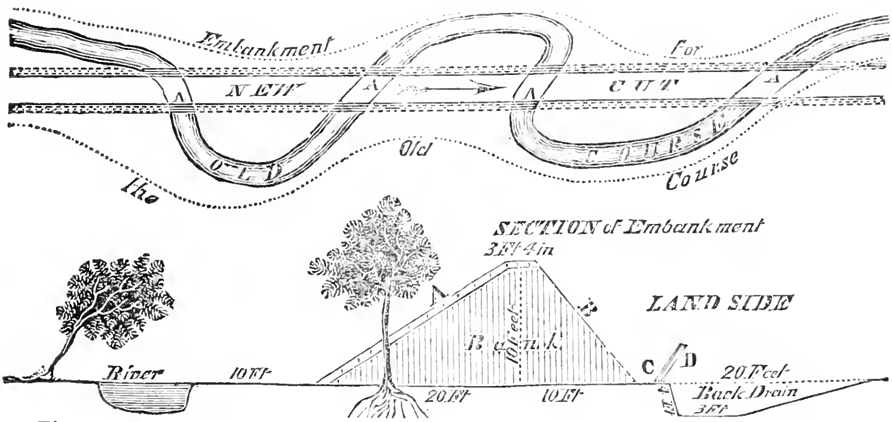
Plate III. *Plan and Section representing a New Channel and Embankment for a River.*

The Points at A should be guarded by a facing of Stones or by Piles of Wood.



The embankments for the new cut is represented by the straight double rows of dotted lines, and should be 10 feet distant from the edge of the cut. The dimensions of the new cut should be 30 feet wide at top, 10 feet at bottom, and 6 feet deep, or in these proportions, according to the size of the stream.

Section.—A, Slope faced with turf. B, Sown with grass. C, Scarcement three feet broad. D, Paling.——Trees must be removed by the roots.

height, and breadth at the base, greater also in proportion. By examining the flood-marks, and measuring their height, that of the embankment may be ascertained; but it should always be raised from one to two feet higher than the greatest flood: for the materials of which it may be formed subside considerably after it has been constructed: and that according to their height. In general, it will be found that rivers which flow freely, and have no interruption in their course, even during the greatest floods, do not rise more than five or six feet above their ordinary level; so that, in most cases, a bank of six or seven feet in elevation will be perfectly adequate for every purpose of security.

The slope of an embankment should always be greater towards the river, than to the land side, in order to avoid that lateral pressure which is so destructive when the bank is formed too upright. The sloping of the bank is of great use in rendering it firm and secure; as it makes the resistance indirect, and of course lessens the pressure of the stream. On the north side of the Tay, between Errol and Invergowrie, there are some old embankments of stone, which rise nearly in a perpendicular line from the water. From being built in this injudicious manner, they have been found so insufficient, that it has been necessary to erect piers or juttees, to protect them from the violence of the current.

The base of an embankment should be *three* times the breadth of its height; and its width at top should be *one-third* of that height, as shown by the section of plate No. III. The line of embankment should be kept at a proper distance from the edge of the river bank, and the stuff of which it is formed should *all* be taken from the land side, to prevent breaking and loosening the surface on that next the river, which would expose it to encroachment from the current. If there are any heights in the field adjoining, within a short distance, the earth may be partly taken from these, and from the cut that may be necessary at the back of the embankment, for receiving the surface-water from the fields. The earth from this cut should be removed with a gradual slope backwards, so as to give an easy descent from the surface to the bottom of the drain. All trees and brushwood should be removed from the space betwixt the embankment and the stream, to give no interruption to the current, or throw the force of the water against the mound. Any tree or bush, in the line of the bank, should be removed by the root; otherwise, it may shake and keep the mound loose at that place, and give admission to the water. A wooden frame of the exact shape and size of the bank should be made, that the workmen may execute it with accuracy; for it is of consequence to have the mound formed regularly, and as even and smooth as possible, that the water may meet with no obstruction, nor take hold of any inequality on the surface of the side next it. In constructing the bank, the earth should be well tramped, and beaten down with heavy mallets, and that part of it of the firmest consistence should be used on the side next the river. That side should also be faced with well swarded turf, as soon as the slope is finished. It may be necessary to pin down the lowermost layers of turf, and to water them (if a dry season), that they may adhere the more firmly, and prevent the grass from decay. The side next the field may be sown with grass seeds, which may also be sown upon the other side, to close the interstices between the turfs, and to thicken the sward.

In executing an embankment, it should always be begun at the upper end, and proceeded with downwards; finishing, if possible, the portion of work for the day, in case of any sudden swell of the river injuring it, if left irregular and not completed. It is not necessary to found the bank any lower than the adjoining surface; the turf only may be taken off, which will be useful in covering the slope, and the earth will unite more readily than it would do otherwise. A *scarcement*, or unbroken space, of two or three feet must be left between the edge of the embankment and the trench that is cut along the back of it. A paling should be erected along the inner side of the scarcement, to prevent cattle from going up, trampling upon, and breaking down the bank, till it be fully consolidated, and swarded with grass.

Embankments are usually executed by contract, and may cost from fourpence to sixpence the cubic yard. The contractor, for the sake of greater security in the execution of the work, should be bound to uphold them for the first two years.

All the water that may collect in the fields adjoining, should only have *one* outlet through the embankment to the river, at the *lowest* point, and that by a pipe or square box of wood, with a valve or lid, fixed to the mouth of it by hinges on the upper side. The valve will shut in floods, to exclude the river, and the pressure of the land water will open it when the flood subsides.

It is improper to sow or plant any tree, hedge, or shrub, that takes deep root, or grows to any height, on the sides or top of the embankment; for by these, the earth would be loosened, the water admitted, and the mound shaken and carried away. If the seeds of rushes, flags, tussilago, or fiorin grass, be sown, these will bind the surface, and prevent the water from making any impression upon it.

Holes made by moles or mice are also dangerous, on account of their admitting the water into the bank, and should therefore be immediately closed up. Lastly, when the smallest breach appears, it should be instantly remedied; for if the water once takes hold of a broken space, it is sometimes difficult to stop its progress. For these purposes, it is necessary to make a frequent inspection, where works of this kind are on an extensive scale.

On the river Spey in Badenoch, the meadows on the estates of Belville and Invershie,* that were formerly overflowed and inundated by every flood, are now embanked in the most complete and secure manner, according to the description that has just been given; whereby above a thousand acres of land are now rendered safe and productive. On the Gordon and Findlater estates, much might be done in the same way. On the rivers Beauly, Carron, Clyde, Dee, Don, Earn, Esk, Forth, Isla, Ken, Nith, Tay, Tiviot, Tweed, &c. a great deal of land has been also embanked in an effectual manner; and on these, as well as many other rivers in Scotland, the extent of land that

* The latter, according to a plan and specification by the author; as also, others of considerable magnitude on the rivers Dee, Don, Eden, Ken, &c.

might be preserved and improved by this means, would amount to many thousand acres.

PART III.

ON THE EMBANKMENT OF LAKES.

All lakes are subject to temporary, and sometimes to extraordinary, swells, occasioned by great falls of rain and snow descending from the mountains that surround them; consequently, they often spread beyond their usual limits, overflowing and injuring the contiguous grounds. The damage they do in these cases is not attended with such devastation as the overflowing of rivers, whose current carries every thing before it, for as the water of lakes subsides gradually, it acts with less violence, and commits less injury. The consequences, however, are always so hurtful, as to make it an object of considerable importance to prevent or lessen them, by confining the water within proper limits.

Lakes that are surrounded with mountains, such as those in the northern parts of Scotland and of England, are known to have increased considerably in height; but in the same time their depth has diminished. This is occasioned by the rapid streams from the hills that run into them, bringing down sand, gravel, and other loose matter, which being deposited in the bottom of the lake, raises its bed, and tends also to choke the outlet, and to retard the discharge. This has also the bad effect of raising the channel, and obstructing the current of such streams as flow *into* them through level ground, and causing these streams likewise to overflow the land adjoining. This is the case with many large lakes, that have stretched beyond their original bounds, particularly that of Loch Lomond, where a small island called Camstradden, which existed in the time of Camden, is now covered with water to the depth of two or three fathoms. At the upper end of the same lake, there is at present a large extent of flooded meadow, that formerly must have been a part of the lake, of no inconsiderable depth.

As lakes subside greatly in the summer season, and swell much in winter, or after heavy falls of rain and snow, it would be desirable to confine them to their lowest limits; and to cut off such creeks and bays where the water is seldom of great depth, and where an acquisition of pasture or meadow ground might be gained. In some lakes, indeed, the extent of surface overflown in winter, so much exceeds what the water covers in summer, that it would be a very desirable object to confine such lakes to their smallest extent. The first thing, then, to be attempted is to enlarge the outlet, that the water may at all times have a free and easy discharge. It would be advisable to deepen this, if the level admits: but in all cases, it will be proper to widen and enlarge it, as much as the expanse of the lake, and the body of water it contains, may require. If rock, this may be difficult and expensive; but may be compensated by the advantages to be acquired, and the certainty of its always remaining open and entire.

The form and construction of the embankment that is to surround the lake, may be similar to that for the sides of rivers, as already described; but as the water, in the former case, presses more directly upon the bank, the slope next it should be greater on that account. The exact degree of slope will depend upon the stillness, or agitation, which the waters of the lake are known to exhibit. In those subject to high waves, from their extent, situation, and exposure to winds, the slope will require to be *twice* as much as that which is necessary for river embankments, where the water presses only in a lateral direction, and where the current glides gently. The embankment should not be confined to the verge of the lake only, but should extend along the sides, both of the stream that flows into it, and that by which it is discharged, as far as the level requires: or must be carried to the higher ground on both sides, above reach of the flood, as shown by the dotted lines marked *bank* in the plan. There must be a back trench or drain to intercept the land-water, and discharge it at the lowest point: and also one, under the high ground, for the same purpose, as represented in the annexed Plate, No. IV.

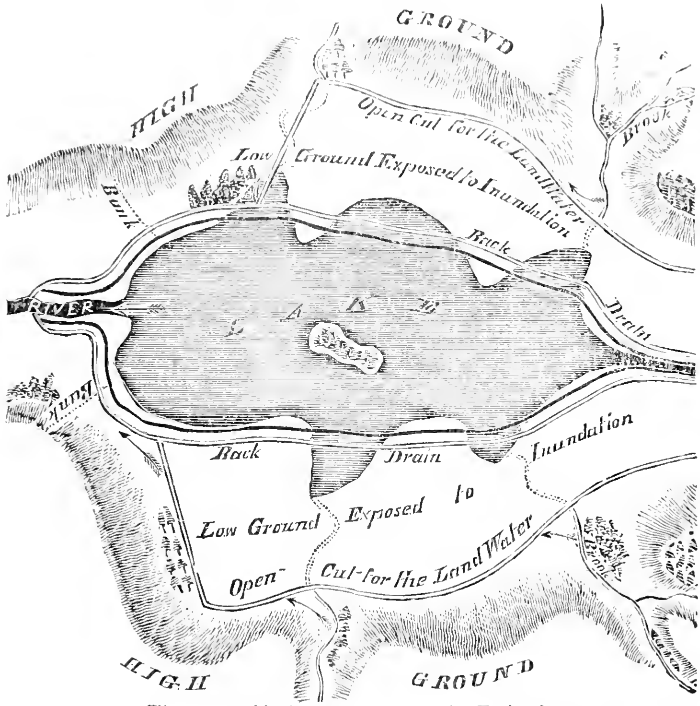
It may be proper to observe, that where a lake is encompassed on all sides by the lands of one proprietor, he may perform such operations upon it as he thinks expedient; but, if the adjacent lands are the property of several individuals, and they have also a mutual share of the lake, every operation on it must be regulated by an attention to their respective interests. Or, if the lake is situated at the head of the river or brook, it may be considered the source of the stream, and no alteration can be made upon it, which may in any degree prove injurious to the proprietors below. It may, however, be remarked, that it is only by such alterations upon the area of the lake, by which an undue portion of water may be taken from, or thrown upon an opposite proprietor, or the general supply of the stream diminished, that a legal cause of complaint can arise: for it is the right of every proprietor to defend and improve his own land, provided it is not done with the evident intention of injuring his neighbors.

PART IV.

ON THE CONSTRUCTION OF WEARS AND DAMS ACROSS RIVERS, FOR THE USE OF MILLS; AND ON THE FORMATION OF BANKS OR HEADS, FOR ARTIFICIAL PONDS AND PIECES OF WATER, &C.

This is a branch of the subject which requires considerable attention; for there is no species of embankment or fence, upon which more money is expended, or where more failures take place. Dams or wears across rivers, for the purpose of raising the water to such a level that it may be conveyed in a lead for the use of mills, &c. are often expensively executed at first; and, for want of being properly constructed, are in constant need of repair, and are sometimes swept away altogether in time of floods. It has hitherto been the custom to erect them in a straight or oblique line across the stream, and to construct the dike in a triangular form, wide at the base, and coming gradually narrower towards the top, where it ends in a point, as represented by Fig. I. in Plate No. V. A dike of this form and structure must be very insufficient, and liable to be disarranged and thrown down by the force of running water pressing upon and falling over it. The upper stones

PLATE IV. *Embankment of a Lake.*



The strong black line represents the Embankment.

PLATE V. *Plan and Sections of Wear and Head for Artificial watea.*

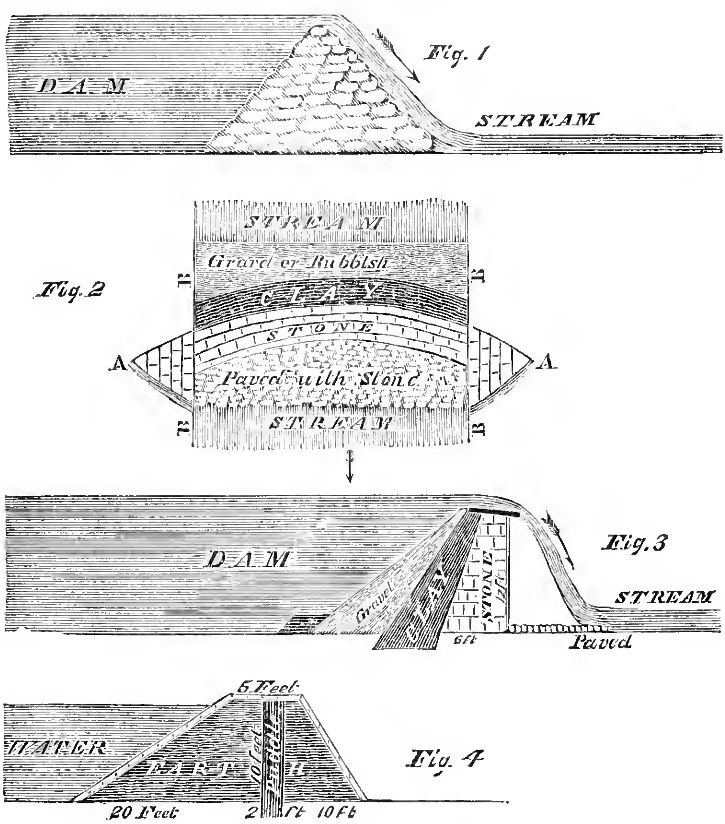


Fig. 2.—A A, Abutment of stone. B B B B, Bank of the river.

are first loosened and carried down, and the water striking with velocity on the whole face of the dike, precipitates itself with violence against those at the bottom, and displacing them, the whole structure is soon demolished.

Dams, that are erected at a still greater expense, of hewn stone, but of a similar construction, are also liable to be destroyed (although in a lesser degree), if the lower side is formed with a slope, or inclined plane. The water, in this case, does not insinuate itself in such a body among the stones that are joined, as it does when they are loosely laid together, as in the first mentioned case; but still, the force of the falling water has such effect upon the undermost layers of stone, that in time it cannot fail to undermine and displace them. The first error in all these kinds of stone-wears, is the carrying them in a *straight line* across the river or stream. They should be constructed so as to form an arch across the bed of the stream, with the convex side upwards, the ends resting on strong abutments placed in the bank on both sides. By this means the force of any body of water, however great, will be effectually resisted, and the structure be perfectly firm and secure. The greater the slope towards the upper side, the better, but the lower side should be nearly perpendicular, that the water may fall over it like a cascade, without coming in contact with the face of the building. Figs. 2 and 3, of Plate V. are a plan and section of this. Dam-dikes, of the construction first mentioned, are sometimes secured by beams of wood, forming a kind of frame-work, in which the stones are placed. But this is liable to accidents, by the wood rotting and giving way; consequently the stones lose their hold, and are soon separated and displaced.

In building the dike or wall, as represented by Fig. 3 in the Plate, it is necessary to dig till a firm foundation be found. The height will be regulated as circumstances direct, and the breadth of the foundation must be according to that height. If the height be twelve feet, the breadth at the foundation may be six, and at top, two feet. The stones should be bedded with as much care as possible, and the joints closely cemented with mortar or *tarras*, that no water may escape, and that the building may be firm and durable. When the wall reaches the requisite height, it should be exactly level across the whole length of the stream, that the water may spread over the whole, of an equal thickness, and so moderate its force in time of a flood; and upon the top, there should be a coping of flat stones, neatly cut and jointed, projecting nearly a foot over the perpendicular wall on the under side, with a rise of a few inches towards the upper side. The length of these stones will require to be three feet; but, if such are difficult to be got, planks of oak, or larch wood, may be used in their stead. That no water may leak through the building, it will be proper to have a bed of clay, three or four feet in thickness, along the upper side of it, well beaten down, and that to the whole height of the wall. The section of clay should be founded lower than the breast-work of stone, to prevent the water escaping under it. The coping stones should be laid on clay or tarras, so that the upper part of the building may be perfectly water-tight, which is a material object in operations of this kind. Gravel, or any loose rubbish, should be tumbled over into the dam, above the clay, shelving gradually from the dike into the water, so as to make the slope as long and easy as possible.

The use of the projection in the coping is to throw the water clear over, so as it may fall at a distance from the bottom of the building. The pavement there will prevent the water making an impression, or opening a cavity in the bed of the river, whereby the wall might be undermined: and it is necessary that this pavement should extend so far as to be beyond reach of the fall when the stream is in flood.

Heads, or banks of earth, for the confinement of water in artificial lakes or ponds, are often constructed at great expense, and not being properly formed, often break out, and occasion considerable damage. The error in their construction is commonly owing to the want of breadth at the base, in proportion to their height; and to their not having a sufficient slope towards the water, nor a proper section of *puddle* in the centre.

Fig. 4, in the Plate No. V. is a representation of what an embankment of this kind should be, according to the supposed depth of water it may have to support. As this bank is acted upon by the water, in a similar manner as that for the confining of lakes, as has been already described, its degrees of slope should be the same, more or less, according to the depth or shallowness of the water. If in a park, or pleasure-ground, the outward slope should also be greater than that of any other embankment, that it may connect more naturally with the adjoining surface, and have as little appearance of art as possible: and shrubs, or clumps of low trees, may be planted on it, to lessen that appearance. Mounds for this purpose are commonly constructed across dens or hollows, where that part of the water immediately above them is of considerable depth. Where this is the case, and the depth exceeds ten feet, the breadth at the base of the embankment will require to be greater in proportion than the section represented in the plate; that is, if the depth is fifteen feet (which it will seldom exceed), the breadth at bottom should be sixty feet; and at top, fifteen. The puddle will require to be equally thick in proportion, and must be sunk several feet deeper than the surface on which the bank is founded, or till a stratum of clay or other safe foundation is got. The mound should be formed of as solid materials as can be got from the space to be occupied by the water; and to render it the more compact, it should be well beaten down, and consolidated in the course of its being formed.

Both sides should be lined with turf, and the water should not be admitted for some months after the bank is completed. For want of attending to this, many heads have given way, by letting in the water, and filling the pond, before the earth was sufficiently consolidated; and it is very difficult to make up a breach in the bank afterwards. Where the artificial mound joins the natural banks, a space should be dug out, to insert, as it were the one into the other, to prevent the constant pressure and agitation of the water at these points from making a breach, and forcing an outlet there. A sluice, strongly secured by mason-work, should be placed in the most convenient part of the bank, to let out the water when necessary; and an overfall, for the waste water, will also be requisite, which ought to be particularly attended to. This should be placed in the solid, or natural bank, at either side, as situation and other circumstances direct, and must be strongly paved with stone, founded on clay; or it may be formed by a sloping tunnel of stone and lime, through the bank, if it rises to a considerable height. This last may, in many cases, be the most advisable, although it is a plan seldom adopted. Sometimes the fall, or outlet for the waste water is constructed of wood; but this is liable to many objections; such as, its alternate exposure to wet and dry, by which means it becomes *warped*, and its joints burst asunder; and its being subject to quick decay, and apt to be undermined and lifted up by a sudden swell of water. If the head is to be erected across a considerable stream, to be widened and formed so as to contain a greater body of water, that it may have the appearance of a river or lake, it may be constructed according to fig 2. in the plate.

In these last embankments of earth (for lakes and artificial ponds), it is particularly necessary to attend to any holes or openings that may be made by moles or mice; for where the water is always pressing against the bank, and ready to ooze out through the smallest aperture, any outlet of that kind should be immediately closed up. A thin coating of hard gravel, immediately below the turf, well beaten down, would tend effectually to prevent the working of vermin of that kind.

CONCLUSION.

In arranging the subject of this 'Treatise on Embankments, &c.' into its proper *heads* and *sections*, that order has been followed which naturally presented itself, according to the degrees of importance which the different branches seem to merit.

Embankments from the sea, are no doubt the first in point of importance, and have a strong claim to the consideration and attention of those active, public-spirited, and wealthy proprietors, whose estates lie continguous to the coast. Where a great stretch of the shore, capable of being recovered from the sea, bounds the property of various individuals, the undertaking should be a joint concern; for, in many cases, it would be easier, and more effectually accomplished in that way, than in separate and detached portions. The expense, too, would be infinitely less, by saving the cross banks that would otherwise be necessary, were only part of a bay of the sea to be embanked at one time.

The ideas of some ingenious and enterprising projectors upon this subject have surmounted the bounds of common understanding so far, as, by their speculations, to have deterred those from entering seriously upon undertakings of this nature, who otherwise might have been willing to execute such plans, on a more moderate and less expensive scale. Persons of this speculative turn of mind, however, are useful in society, so far as they are the means of setting others to think of enterprises that some time or other may be carried into effect. Many great works have, in time, been executed, that were originally suggested by projectors of this description, whose speculations were then looked upon as the mere chimera of a distempered imagination, and absolutely beyond the power of human exertion to accomplish.

England has already shown the practicabilty of these improvements in the art of embanking, in all its various degrees; and it is hoped, that this part of the kingdom will profit by her example.

The second branch of this subject is less open to these objections. That the *improving the channels of rivers, and embanking the land liable to be injured by their overflowing*, is an operation of more practicability, must be generally acknowledged. The benefits to be derived from it are equally certain, and are more easily attainable.

That of lakes, of the nature and description that has been given, has likewise its claim to attention. There are many in Scotland, where a great addition of useful land might be acquired, and that in parts of the country where an acquisition of this kind would be doubly prized. Such would the case in those highland districts, where low-lying ground is of the greatest value, for the purposes of culture and the produce of hay for the winter maintenance of stock.

Lastly, the works that are erected, both for use and for pleasure, in the *construction of dam-dikes and formation of artificial ponds of water*, are often faulty in the design, and expensive in the execution. The rules and directions for these have been suggested from observation in different parts of the kingdom, where the writer has had the opportunity of viewing and examining them, as well as from his own experience in planning and directing works of the same kind. *Of sea-dikes and river embankments*, he has also, in the course of his profession, had the designing and direction. He has, therefore, with some degree of confidence, treated that part of the subject; and can safely recommend to the notice of those who may be desirous of undertaking such works, the various modes of execution that have been explained. At the same time, in submitting these observations to the public, he deems it proper to add, that they are, in a great measure, corroborated by the opinion of others who have written *partly* on the same subject, and whose communications he has consulted. He has avoided entering into a lengthened detail; but has endeavored to explain the whole system of embankment, in as concise and perspicuous a manner as the nature of the subject would admit.

If this short treatise, therefore, shall be the means of promoting the knowledge, and extending the practice of these useful undertakings, he will feel the satisfaction of having, in some degree, contributed to that effect.

APPENDIX.

HINTS AND DIRECTIONS FOR THE CULTURE AND IMPROVEMENT OF BOGS, MOSSES, MOORS, AND OTHER UNPRODUCTIVE GROUND, AFTER BEING DRAINED.

It has been wisely remarked by the late excellent Bishop of Llandaff, in his 'Preliminary remarks to the Agricultural Report of Westmoreland,' that "the *waste* lands of the kingdom are a *public* treasure in the hands of *private* individuals."

It is from waste lands, not hitherto *completely cultivated*, that the greatest profit can be made (when once brought into culture), rather than from land which has been long under the plough; not merely from the rent of such land being comparatively low, but, from all *new land, when improved*, yielding, when properly managed, more *profitable* returns, than can be obtained from those soils that have been long under cultivation. No object in nature can appear more unpropitious, than an *undrained, uninclosed,* waste tract of ground, overrun with heath, rushes, and other useless plants, producing the most stinted herbage, and giving an appearance of sterility, even to the cultivated parts that may adjoin or surround it. Notwithstanding these unfavorable appearances, however, such land is, in a greater or lesser degree, according to situation and climate, capable of improvement; and, *when improved,* rewards the cultivator in a tenfold degree.

The next thing to be considered, after a bog, moss, or other kind of marshy ground, has been *completely* drained, is, the means most easily accomplished, and best adapted for its further improvement.

If such ground is overrun with rushes and other coarse aquatics (which is almost always the case), nothing will tend more to the *first part* of its improvement, than *over-stocking* it with cattle, so soon as it acquires a sufficient degree of solidity to bear them with safety. But care must be taken not to put them on it till it be *sufficiently* firm; otherwise the surface will be poached, and the coarse herbage not closely eaten down. By this means, the strength of the *rank* grasses will be nearly exhausted, and the roots will decay for want of their *accustomed* moisture. The trampling and pressure of the cattle will also help to consolidate the surface. By this first process alone, a wonderful change soon takes place; all the aquatics soon decline, and give way to better grasses, which spring up in abundance.

Lime or marl, spread on the surface, will greatly increase the growth of white clover, and other kinds of fine natural herbage, after the rushes and coarse plants have been closely cut, and eaten down by the cattle.* The first thing, however, to be done, whether the field is to remain in the natural state of pasture, or to be cultivated by tillage, is to level the surface; the natural irregularity of which is, in most cases, an obstruction that ought first to be removed. The earth that composes the highest parts should be removed, and mixed into a compound with lime, to be used either as a manure for a crop, or spread on the surface as a *top-dressing* for grass. Earth of inferior quality may be substituted for filling up the deepest hollows. Where the nature and situation answers, no improvement is so cheap, so sure, or so profitable, as converting a certain class of bogs into water-meadow.†

If it lies along the side of a river or stream, of which, by means of proper dams, trenches and sluices, a command can be obtained; and if the process of irrigation is managed with skill and attention, it never fails to produce luxuriant crops of grass. This crop is in every respect best adapted to the nature of such ground, being less affected by the inclemency of a cold or moist climate, and giving a more sure return, without the labor and expense of annual culture, than any crop of grain that might be produced. As a proof of this, the water-meadows on the estate of Odstone-Hall, in Leicestershire (already alluded to), from being mere bogs, before they were drained by Mr. Elkington, now produce as abundant crops of grass as any of the kind in that part of the kingdom. As a further instance of the good effects produced by watering this kind of land, Mr. Boswell, in his treatise on that subject, says:—"Lands that are very boggy, require more and longer watering than any sandy or gravelly soil. The larger the body of water that can be brought upon them the better: its weight and strength will greatly assist in compressing the soil, and destroying the roots of the weeds that grow upon it; neither can the water be kept too long upon it, particularly in the winter season, immediately after the *after-meat*† is eaten; *and the closer it is fed the better.* This species of soil, after being *well drained* and watered, will equal the wishes of the most sanguine, by its improvement."

No general system of irrigation can be properly laid down, applicable to every particular case, farther than some general directions, that hold good in every situation: but, in other parts of the process, different modes must be adopted, according as the situation and form of surface require. In those where the command of a river or stream can be obtained, the general rule is, to collect a sufficient quantity of water, nearly on a level, in a main carrier, which can, by means of sluices, constructed at proper places in the sides of it, be let out into floating trenches, cut along the surface of the field, or sides of the declivity, one below another. These floating trenches will collect the water from above, after passing over the spaces of ground betwixt each, and distribute it equally over the surface of each space lying between them, alternately. Proper attention must be paid, at the proper seasons, to open and close the sluices, in regular rotation, so as to flood different portions of the land successively; and the floating gutters should frequently be cleaned and scoured out, to prevent their choking up, and to destroy the growth of rushes, or other grass that may grow up in them. From the very absorbent quality of the peat, the water would require to have a more rapid motion on bogs, than on soils less porous or spongy. The saving of manure is another circumstance in favor of water-meadows, as the application of it would appear to be of no material consequence, being very seldom used by some of the best flooders in England.* Still, however,

---

* The best time to cut rushes, &c. is when the shoots are weak, and before the seed comes to maturity. If left till the seed is ripe, it is shaken out, and, falling on the ground, multiplies their growth. They should be *frequently* cut before this season, which will soon extirpate them.

† It must be understood, that the surface of the bog has been properly levelled, well rolled, and a good sward of grass on it, before the operation of floating can be attempted. It is a fact well ascertained, that in Merionethshire there is land that was formerly not worth 6*d.* per acre; but being now *drained and flooded,* besides affording excellent pasture till the 1st of June, produces two tons of good hay, cut in the beginning of August.—*Agricultural Report of Merionethshire.*

† Or *latter-math,* as it is commonly called; that is, the pasture or after-grass, when the hay has been cut.

* The late celebrated Bakewell, who was a great advocate for watering, used no manure on his water-meadows. It was a favorite idea of his, that water made to float over the greatest bog or swamp, *without being drained,* would not only have the effect of producing a finer herbage on it, but that the pressure of water artificially brought upon it, would force back that with which it was already overcharged, into the

lime or shell-marl dissolved in the water of the upper carrier, would be attended with the most beneficial effects. Its finer particles would thus be intimately diffused over the surface, would be lodged in closer contact with the roots of the grass and afford them additional nourishment to what they receive from the fertilizing qualities of the water. The operation would be simple, and the expense trifling, from the small quantity of lime sufficient for the purpose. The lime should be laid down along the side of the uppermost trench or carrier, and, after being *slacked*, put, in small quantities, among the water in the cut, and, being stirred about, would be carried down by the stream, and equally diffused over the surface. It is to be observed, that the lime, or shell-marl, is only to be used in this manner, the last days of the watering for that season. The refuse of salt, used in this manner, would be a valuable improvement; its fertilizing qualities being equally beneficial on pasture, as well as on arable land.* These experiments the author has not seen practised, though he here recommends them; but it is obvious to every one who is in the least acquainted with the object of flooding, and with the qualities of these manures, that it must prove beneficial, beyond a doubt.†

As it is only in certain situations where this mode of improvement, by means of water, can be adopted and practised with advantage, it is necessary to take notice of the other means that may be used, and that are best calculated for the improvement of bogs, by converting them into a state of cultivation so soon after draining as they become accessible to the spade or the plough.

If the bog is of considerable extent, the first thing to be done after draining, or which may be done at the same time, is dividing it into proper inclosures, by open ditches.

These will assist in carrying off the surface-water, which the covered drains do not effect; and part of the earth thrown out of them may be mixed in a compound with dung and lime, or made use of in filling up some adjacent hollows. If the ground is to be pared and burnt, part of it may be burned along with the turf; but this is supposing that no thorns or quick-fence is planted along the ditches; in which case, no bank of earth is requisite on either side. In ploughing, regard must be paid to the proper direction and inclination of the ridges and furrows towards the open ditches, in order to discharge the rain-water as it falls. The great object is, to get the ground brought into such a state as to be fit for being laid down with grass-seeds, after which it may be considered in such a state of improvement, that any subsequent crops will require no more than ordinary management to cultivate. Some bogs, when *too much drained*, are apt to become parched in dry seasons. To remedy this, if the ground is very flat, or nearly level, sluices may be placed in the lower end of the division-ditches, which, in very dry seasons, may be kept shut, to *retain* the water received from the top-drains. If the ditches have a descent, so that the water cannot stand level all the way, several sluices of this kind will be necessary; or the water may be stopped, by building in turfs. The water may be allowed to stand within a foot, or a foot and a half, of the surface, and, by its stagnation, will ooze through the peat, or upper soil, and afford such a degree of moisture as will greatly relieve the crop. If in pasture, the cattle should not be allowed to feed on it while the water remains in the ditches, nor for some days after, as they would *poach* the surface too much, and the heat would induce them to go into the ditches, from which they might not easily get out.

In levelling or smoothing the surface, it will be necessary to use the spade, by which the work will be done nearly as expeditiously, and much more effectually, than with the plough at first. There are various opinions, how far paring and burning is conducive to the improvement of land. Some have condemned it, as a practice that ought to be exploded *on every soil;* yet, on a certain class of boggy ground, it may be considered as a very great improvement, not only from the excellent manure that the ashes produce, but also from its destroying the roots of every noxious plant more effectually than could be done by means of fallowing alone. The ashes of the burnt turf;

---

channel from which it sprung. That nothing can be more absurd, the following fact will prove:—At Drayton-park, near Tamworth, in Staffordshire, a considerable extent of bog was thus watered, by a cut for that purpose, conducted under the direction of Mr. Bakewell, at a very great expense, and which, after being completed, had the effect of rendering the ground much worse, and more swampy than before. This, to the surprise of Mr. Bakewell (but not entirely to his conviction), not having the effect which he argued it would, Mr. Elkington was applied to, who, by means of a drain which he made, and which did not exceed *one-third* of the expense of Mr. Bakewell's water-works, has rendered the ground worth *ten times* its former value, and it now produces crops of grain equal in value to any that is produced in that country. This is mentioned, as a proof that land of that description, without being previously drained, can never be watered with advantage.

* In a communication to the Board of Agriculture, on the nature and qualities of salt, as a manure, by Mr. Roalfe, of Sandwich, he says—"Salt is also excellent upon rushy and sour pastures, which are subject to occasion the rot in sheep: such is its effect, that it prevents that destructive evil from attacking them."

† A method nearly similar to this, seems to be practised in watering ground in Switzerland, as appears from the following remark in a treatise, entitled, "Le Socrate Rustique," 1764:—"Our cultivator considerably augments the vegetative properties of the water by *rich mould*, procured, as I have already mentioned, from green turf, cut from eminences in pasture, or from fallow land. This he throws into the principal head of water, so that the lesser channels may imbibe and communicate fertility over the meadow." In a note by the translator, alluding to this passage, he says—"This is a good thought; but the benefit on some soils, of casting *slacked lime* into the stream, would be much greater, and acquired at a much less expense."

Another method, practised by Mr. Miller of Dunstall, in Staffordshire, merits attention. On the stream which he applies to the floating of his ground, are two ponds, for the purpose of supplying mills situated below. From these ponds the floating trenches are supplied; and as there is always a quantity of fine mud deposited in the bottom of them, this he stirs about, so as to be carried along with the water, and equally distributed over the surface. The success of this practice warrants its recommendation.

Although the watering of land is now arrived at a very great degree of perfection, yet these hints seem to have escaped the attention of most practical flooders.

when mixed with the soil by a superficial ploughing, so enrich it, as to produce excellent crops, for two years at least, and if a little lime is added, it will help sooner to pulverize and stimulate the soil. If the bog is covered with long heath, or ling, and other coarse *benly grass*, it might be proper to burn it *growing*, without paring off any part of the soil. But this would yield only a small quantity of ashes; neither would it destroy entirely the roots of the plants, and, when ploughed in, would produce very little effect. So soon as the turfs are reduced to ashes,* they should be equally spread over the surface, ploughed in with a light furrow, and turnip or potatoes ought to be the first crop. If the former, they should be sown *broad-cast*, and fed off with sheep. By this the soil will receive great benefit from the dung and urine, and from the refuse of the plants, and by its being consolidated by the trampling of the sheep. It will then be in good state for a crop of oats or barley, which should be sown with grass-seeds, well rolled down. The ploughing, after the turnips are eaten off, should be very slight, not to bury the sheep's dung, &c. too deep; in which case, a crop of oats is preferable to barley, as the preparation of the ground requires less ploughing. If the soil is full of the roots of rushes, and other weeds, a course of summer fallow will be requisite, before any crop is taken; and if the ashes have been made in one corner of the field, they can be spread over the surface, before the seed-furrow is given; and the roots and tough clods may be collected into heaps, burnt, and spread along with them.

If the bog is deep of peat, and very soft, so as not to be fit to bear horses in the act of ploughing it the first year, a crop of *turnip broad-cast* may be got, by sowing the seed among the spread ashes, harrowing it in with a light harrow and roller, drawn by men. The turnip should be eaten off with sheep, and the ground will next year be so much consolidated, as to admit the plough.

If the surface is not pared and burnt at all, a course of fallow, even for two years, will be necessary, to reduce the soil to a proper mould; in the last stage of which, the lime, or other manure, may be applied. In this case, two white crops, with an intervening one of turnip, potatoes &c. may be taken, before the grass-seeds are sown.†

All boggy soil whatever, after being once broken up, and pulverized by tillage and a course of summer fallow, should not be overcropped before being laid down in grass; and when once brought into a good *sward* of grass, should not be too soon broken up, but continue so, brush-harrowing and top-dressing it, when the herbage begins to fog. Frequent rolling is also very necessary on such soft soils.

It is better to feed sheep the first and second years on the grass, than to cut it for hay, as it causes the roots of the plants to strike more horizontally through the soil, and more closely cover the surface. For this purpose, a greater proportion of white and yellow clover, and other short *grass*-seeds, should be sown. In the second breaking up of the ground, after lying some years in pasture, no particular mode of practice, or rotation of cropping, can be laid down. The state of the ground, then, must be the rule for after-management, by which time it will not only have attained a firmer texture, but also a degree of strength to produce any crops, with proper manure and cultivation. In manuring soft boggy soils, one precaution is necessary. The deeper the ploughings are, previous to the dung being laid on, the better; but the subsequent furrows should be very superficial, and the dung intimately mixed; for when it is ploughed in too deep, not equally distributed and incorporated with the soil, it is apt to subside below reach of the plough, or horizontal roots of the grain. The same is the case with lime, which always penetrates deeper into the soil; and marl, when buried too deep, loses all its effect.*

Upon soft boggy land, intended only for pasture, nothing will work a more quick improvement than covering it with a thin stratum of clay, gravel, or any other earth heavier than that of which the bog is composed. Clay-marl, where it can be got, is of all others to be preferred, both on account of its greater weight, and enriching qualities. Sea-sand, being mixed with shells, is peculiarly adapted for this purpose, if the bog is situated near the sea, where such can be easily got. The weight and pressure of these heavier bodies makes the bog soon become more solid, and likewise presses

---

* In burning the turfs, after they are properly dried, they should be set up in *large heaps*, adding to them as they burn. This confines the smoke and flame, by which so much of the essence is evaporated and lost, when the turfs are burnt in small heaps.

Paring and burning the turf, is, in some places, begun in the month of March; but it is better to delay the burning till April or May. The paring, however, may be done in March, and the turfs will be dry enough for burning in the month following.

† Rye, being a hardy grain, and thriving on very poor soils, is a very profitable crop on *drained boggy land, pared and burnt*, as appears from the following extract of a communication to the Board of Agriculture, respecting the state of husbandry in the neighborhood of Petersburgh: "Rye-bread, as every body knows, is the chief support of this district, as well as of the other northern parts of Russia; but, in order to save the rye-flour, and to make it last the longer, the inhabitants, when compelled by necessity, mix with it *fine-ground oatmeal*, the meal of buckwheat, and the husks of the field mustard seed *(sinapis arvensis)*. The produce of rye in very few places varies more than here. The poor sandy lands will hardly produce more than three times the quantity sown. The middling sorts of land produce four and six times the seed. The rich and well manured lands, and such where wood has been cleared off, will produce, in a good season, ten or twelve for one sown; but the most extraordinary produce is gathered from *boggy lands, drained*, and sown with rye; as in a favorable season it increases forty times and upwards. The reason of this extraordinary increase must be explained: it is owing to the ashes produced *by burning the bogs*, which assist the vegetation to that degree, that frequently they find one grain produce forty plants, and even more; for this reason, they generally use a much smaller quantity of seed in sowing such land. There is no need to sow clump rye *(secale multicaule)* upon such lands, as any good common seed increases very much upon so rich a soil, to which the burning of the surface has added so much of the vegetative power. The seed is sown in July or August, and is reaped about twelve months after."

* Coal ashes form an excellent manure for sour wet land, either used as a top-dressing for grass, or, if ploughed in, tend greatly to destroy the tenacity of stiff soils, and render them more productive.

out more quickly the moisture contained in the spongy peat; the thicker, therefore, it is laid on, the better. A thin sprinkling of lime over it, will add to its effect, and cause white clover, and other sweet grasses, to spring up in greater abundance. The most barren soil will have a good effect, when used in this manner; but, of all others, limestone gravel is preferable. By means of it, many extensive bogs are improved in Ireland, where it abounds; but very little of it is found either in England or Scotland, which renders that mode of improvement impracticable. After the ground has been thus treated, and lain some years in pasture, it may be broke up by tillage, and crops of grain taken, before being laid down with *grass-seeds*. By ploughing it, part of the natural soil will be turned up, and intimately mixed with the earth, &c. that has been laid upon it; and, if lime or dung is added, will altogether form a very fertile mould.

Such are the methods by which many bogs have been cultivated and improved after draining, in several parts of the kingdom, the success of which is a sufficient recommendation of the practice. But *these hints* are not to be considered as the only means whereby this improvement can be effected. There are others equally beneficial, and, in many situations, equally applicable; by means of which, there is no doubt that much *boggy ground*, however barren in its natural state, may soon be rendered highly productive; but to enumerate these, would be unnecessary; for every one who possesses ground of this description will be able to ascertain what mode of management is best calculated for its situation, what crops he wishes to raise, or what kinds of manure he has in his power to apply.

As no method yet practised for the improvement of moss has equalled, in produce and profit, that so successfully introduced by Mr. Smith, of Swinridge-Muir, in Ayrshire, a short account of the process, and result therefrom, may not be unacceptable to many readers. *

The moss is of two different kinds—the black, and the red or flow-moss. Both are are of a considerable depth, from four to twelve feet; but the first is reckoned more valuable, in several respects, than the other.

The first thing is, to mark out and cut proper drains (taking advantage of the declivity), to draw off the superfluous water, and to divide the moss into separate small enclosures. These drains, or ditches, are commonly eight feet wide at top, two feet at bottom, and four and a half feet deep, when first cut; but as the moss afterwards subsides, they become less; they cost 2*d.* per lineal yard. After these have been cut, and the moss thrown out has been spread from the sides, and the hollows filled up, the ridges are marked off, parallel to the sides of the enclosure, twenty feet in breadth. They are formed by leaving a space of twenty inches untouched in the middle of the ridge, and turning up on each side of this a furrow with the spade, which is laid over the untouched space, so as to raise it to a proper height above the sides. The whole breadth is then dug, by turning over, with the spade, furrows a foot in width, which has the appearance as if done by the plough. The division-furrows are small drains about two feet deep, and as wide, for drawing off the superfluous moisture, and conveying it into the main drains. The ridges must not be formed too high nor too narrow, nor the furrow-drains cut too deep; otherwise the moss will be left too dry, and consequently prevent the action of the lime which requires a certain degree of moisture to have a proper effect. * The next thing is *top-dressing* the ridges with *newly slacked, or powdered lime*, at the rate of 500 Winchester bushels per acre, † *i. e.* 250 bushels of shell-lime. The moss is prepared for the first crop early in the summer preceding; in which time the lime, aided by the effects of the different seasons, has so far meliorated the soil for the reception of the seed.

Potatoes planted in the *lazy-bed* way, ought always to be the first crop, when dung can be got. ‡ The potatoe-beds are formed across the ridges. A thin layer of dung is then spread over the beds, and the cuttings laid about a foot asunder, and covered (to the depth of a few inches) with the mould taken out of the trenches between the beds. When the plants appear above ground, they get another thin covering, by a second scouring of the trenches; and they require no hoeing till they are taken up. The produce is never less than forty or fifty bolls, of eight Winchester bushels, and the quality excellent. When the potatoe crop is removed, the ridges are again formed in the manner as before, and the division furrows cleared out.

In this state the ground remains till next spring, when oats are sown and harrowed in with a small harrow, drawn by men. The early oat is always preferred for seed, the late seed running too much to straw. The produce of the first two crops of oats is seldom less than ten bolls (of six Winchester bushels) per acre, and that of the succeeding crops, six or eight bolls, and often more. Five or six successive crops of oats are often taken, without receiving any additional manure, or exhausting the strength of the moss. By this time its nature has undergone a considerable change, and has now the appearance of a rich black mould, and is sown down with grass-seeds. It is not so favorable to the growth of barley, which is never sown before the first grass. When no dung can be had the first year, and oats taken with lime alone, the crop often misgives; which is a proof that, *without dung, and potatoes for the first crop*, it cannot be productive. The different kinds of marl are well adapted, and many sometimes serve as a substitute for lime; but dung is an inseparable appendage. After the process thus described

---

*The author visited Swinridge-Muir, when the moss was preparing for crop 1793; and this account of the process is from his own observation, and partly from what was communicated to him at the time. He takes this opportunity of testifying his regard for Mr. Smith, whose life, he has no doubt, has been *prolonged* by his *draining* and *improving* this large tract of moss, in the *centre* of which he has now attained the patriarchal age of *eighty!*

* In very dry weather, this may be remedied, by stopping the lower end of the drains, and retaining the water; and if there is a command of any spring, or higher water, it may be let into the main ditches; but too much moisture is likewise to be guarded against.

† Scotch; equal to one acre and one-fourth English.

‡ The quantity of dung is about eighteen or twenty single-horse cart-loads to an acre.

has been gone through, and the moss lain a few years in grass, it can be ploughed safely with horses; which lessens the annual expense of labor, without diminishing the produce. The spade is the only implement for the first years; and it is astonishing with what neatness and expedition the accustomed workmen perform the operation. It is sometimes ploughed the fourth year where the moss is not very deep.

When laid down with grass-seeds, the hay crop is often abundant, and the pasture, afterwards, worth £1 5s. per acre; which shows that the preceding oat crops have not exhausted too much of its strength. Rushes are very apt to grow up in the pasture: and the *poaching* of heavy cattle ought carefully to be avoided in *wet seasons*.

Abstract of the annual expense and profit per acre, for five years.

	Crops.	*Expense.*	*Profit.*
1st year	Potatoes,	£15 18 5	£0 11 7
2d "	Oats,	3 2 0	4 3 0
3d "	"	3 11 4	3 13 8
4th "	"	3 5 2	1 0 10
5th "	Hay,	0 12 0	3 4 8
		£26 8 11	£12 13 9

Average profit, £2 10 9 per annum, and will let for £1 5*s*. per acre, in pasture. By this, it does not seem so necessary to lay down with grass, after once manuring it, as in dry land; for the crops fail little in produce; and the great desideratum is to have plenty of straw for producing dung, so invariably requisite for the first crop. An intervening crop of turnips, however, would be an improvement in the rotation.

The different articles of expenditure making up this abstract, are stated at the highest rate, and the articles of produce equally low; so that, on the whole, it may be reckoned a fair average; but the distance from lime, in many places (which is here at hand), must alter the calculation, and increase the expense.

A great deal of moss has now been improved, by cultivating it in the same manner, in the counties of Ayr, Renfrew, and West-Lothian; and, indeed, these examples have been the means of inciting others to follow the same practice in different parts of Scotland, and which is every day becoming more general.

So far, these *hints* and *directions* were given in the editions of 1797 and 1801, and apply more particularly to *spring bogs, marshes*, and *peat-moss*. The following further observations and directions were communicated by the author to the Board of Agriculture in 1801, in a separate form; but were not then published. They are now added, as being connected with the subject. As there was a general scarcity in the country at that time, the Board recommended bringing into tillage all land that was capable of being drained and brought into cultivation, at a remunerating expense; and accordingly the substance of what follows was then communicated.

There is certainly no other means by which a sufficiency of grain for the maintenance of the people, and of improved pasture for that of live stock, can be accomplished, than by that under consideration.

A great portion of the land under this description, is, in its present state, altogether unproductive: but when drained and cultivated in the manner recommended, would become valuable, either under a regular rotation of cropping, or, after being properly laid down, kept in permanent pasture.

There are various circumstances which must guide the possessors of such land in the mode of treating it, which cannot be fully adverted to; but the general hints and directions here given, relative to the different soils, &c. it is presumed will apply to most cases.

I. *Very old pastures, over-run with rushes, fog, or moss, that have been long out of cultivation, but where the soil is strong, and the climate is good.*

In regard to *ploughing* ground of this description for the *first* crop *it* ought to be *deep*, in order more effectually to bury the moss,* and bring up a *fresh* mould, which, besides, will render the crop less luxuriant in straw, and consequently not so apt to *lodge*: and next year's ploughing in the same way (deep) will expose, in a more mature state, the surface that has been turned down the year previous.

In soils of this description and quality, the great object is to obtain *two* valuable crops in the two *first* years, without the aid of manure, or the intervention of a green crop or summer fallow, when such management does not tend to deteriorate, or exhaust the productive powers of the soil. Therefore, in this case, the first and second crops may be oats. If the ground has been in tillage before, though long neglected, and has been limed before being last laid down in grass, or has been top-dressed with lime in the course of its being in pasture, there will be no need for giving it more lime during these two crops. If it has not been limed, or at so early a period that its effects may now be exhausted, it will not be advisable to put on the lime till the *third* year, as will afterwards be noticed. It will be necessary to attend, in the first place to the proper ploughing and harrowing; as by that, a material saving of seed will be gained. When the furrows are laid over unequally, too thick, or too broad, openings are left between, and in these interstices an unnecessary quantity of seed is swallowed up, which either never vegetates, or if it does, is so weak as to be good for nothing. To remedy this, the simple plan is, to give the ground a slight harrowing *up and down* (not across) the ridges, by which the openings between the furrows will be so much filled up as not to endanger the seed. Indeed this will be attended with another advantage, that of encouraging the whole to come up more early and regular, than would otherwise be the case. All the harrowings should be given in the same way, as there is a risk of reverting the furrows when done cross-ways. Rolling, too, is useful in this case, to destroy slugs and worms which infest ground of this kind in the first crop, and which are often very destructive. As to the form of the ridges, none can be prescribed for the first two years, but to plough the land in the same shape

* Moss, here means, what in Scotland is called fog, of so thick and close a texture as to destroy, in a great measure, the growth of any nutritive grasses.

as it may have been before, even though the ridges should be broad, crooked, and unequal. Improving the ridges, by levelling and straightening, will be better performed during the third year.

The whole of this soil, the third year, should be under green crop, with the usual preparation and manure. It would be needless to say what manure is best adapted, or how it should be applied, as these circumstances depend entirely upon the various situations in which such land may be placed. The lime necessary should be spread on and ploughed in with the last furrow only, if the ridges require any levelling or new forming; but if not, this rule need not be adhered to, and the lime may be laid on after the first ploughing, by which means it will be more intimately mixed with the soil. If there is not a command of dung for the whole of the soil that may have been broken up, and it may not be convenient to have the whole under potatoes or turnips, the remainder cannot be better occupied than in tares or vetches, which, cut green in the end of summer, will afford excellent feeding for the working horses. By the consumption of these in the house, a sufficient portion of dung may be made for manuring this part of the ground for next crop.

The application of the turnip to stall-feeding, or eating off with sheep, either on the turnip-ground in hurdles, or by the same kind of shifting inclosure, in an adjoining field, will depend on circumstances. Where the ground has been sufficiently manured, it would be preposterous to feed them off in the field where they grow; and in this case, they should be carted off, either to the house-feeding, if that is wanted; or to be eaten with sheep on some grass inclosure that is to be broken up, and is in need of manure, or perhaps, as a top-dressing to some stinted pasture; or, part of them may be eaten off with sheep on that portion of ground which had got no dung, and had been under tares.

It is found to answer well, and prove very beneficial, to take up part of the turnips early in the season, when they are in the most nutritive state, and by cutting off the *shaws* (leaves), to pile them up in small stacks or heaps, securely covered with straw within a house or shed; and in this state, if the frost be excluded, they will keep sound for several months. * It is of consequence to clear the ground in this way, when the succeeding crop is to be wheat, and when the consumpt cannot be so immediate as to clear it otherwise. When barley or oats is to be the next crop, it is not so material; but at all events, the saving from frost is a great desideratum, and therefore, worth attending to; and having them always at hand when the ground may be covered with snow, and thereby a difficulty in collecting and carting them off. In this class of soils, and where the climate and other circumstances favor it, wheat should be the fourth and last crop sown down with grass-seeds. As the chief object may be, to get this land soon again into pasture, only one cutting for hay should be taken, and the after-grass not too closely eaten down.

By the management and rotation here specified, it is evident, that a very great additional supply of grain will be produced, without deteriorating the soil so much as to render its future produce in grass less valuable; but on the contrary, it will be so much refreshed and renewed, as afterwards to yield an abundance of good pasture, in place of remaining in its former unproductive and unprofitable state.

II. *Old pastures, wet and over-run with rushes and coarse grasses; the soil clay, or clay-loam.*

So soon as the draining is finished, which ought to be in October (or before, if it can be accomplished), the rushes should be closely cut by a strong, short, and broad scythe, made for the purpose; and the ground ploughed with a deep furrow, so as to bury the stools, and expose the roots and seed-bed to the winter's frost. What part of this soil may not be so wet and rushy, should not be ploughed with a deep furrow, but with one of eight inches broad and six inches deep. This ground should be limed on the sward (surface) with newly slacked lime, and immediately ploughed in. The first crop invariably should be oats, and the second may be beans and peas broadcast; or drilled, if the soil be sufficiently pulverized by cross-ploughing and harrowing. No ground, unless it be very foul, and absolutely unfit for green crop, should be put under fallow, as thereby a crop is lost; but neither of these (over-foulness, or too tenacious a soil,) can be the case with the ground here alluded to, after the previous treatment it has undergone. Indeed, the nature of the soil is not adapted to such green crops as turnip and potatoes; but a profitable crop of drilled beans, or of cabbage, may be raised, while the ground is undergoing (by the necessary operations of hoeing and cleaning) a state of preparation nearly equal to that of a fallow.

The fourth and last year, this ground should be sown with barley and grass-seeds. Barley in this case is preferable to oats, because the soil being close and retentive, there is more time to prepare and pulverize it by frequent ploughings, &c. for the reception of the seed. As it should only be cut one year for hay, the quantity of pasture grass seeds should be in a fuller proportion.

III. *Light soil inclining to sand.*

This should be broke up with a crop of oats the first year, and with a very light furrow. Next year's crop should be turnip, manured with a compound of lime and strong earth, such as scourings of ditches, cleanings of ponds, &c., or clay marl where it can be had; and the turnips should be fed off on the same ground, either with sheep or black cattle, in hurdles. The turnip, in this case, may be sown in broad cast, with a less proportion of manure, as that from the sheep or cattle, while eating them off, will add a store of matter to enrich the soil, and the trampling and treading, &c. will help to consolidate the looseness of it. Barley, with grass-seeds, next year (the third), will not fail to be a good crop; and it will be pre-

* There is an excellent method of preserving turnips, by cutting off the *shaws* and *tap-root*, and setting them in regular layers on old pasture. The bottom part immediately sends out fibres through the grass, and preserves the bulb or body of the the turnip *entire* for several months. Straw or grass laid over them, excludes the frost, and so prolongs their nutritive qualities.

ferable to sow only for pasture; in which case, less red clover, and a larger proportion of white and yellow, will be proper.

In this light and loose soil, the grass-seeds should be sown after the barley has got *one* harrowing; and it will be necessary to roll it well when the other course of harrowing has been completed. There may be other rotations for this kind of soil, but none better adapted to it; nor any that will return a profit so easily, and leave it again in an *improved* state of pasture.

IV. *Another class of light soils, wet, the pasture stinted and unproductive.*

Here, the surface being less rugged and uneven, it may be manured on the sward with a compound of lime, earth, and farm-yard dung, at the rate of 100 cart-loads per acre. This should be ploughed down in the months of October and November, and sown with oats early in spring. The second crop should be peas with two furrows; and the third and last crop, oats, with grass-seeds, for pasture only. The compound should be made up some months previous to its being used as manure; and should be once turned over, to accelerate its decomposition, and render it more easily incorporated with the soil.

V. *Another class of similar soil, having the surface over-run with coarse grass, heath, &c.*

If this soil is of sufficient depth, it will be advisable to pare and burn it before the first crop.* When this is done, 150 bushels of well slacked lime to the acre should be spread on it, along with the ashes, which will ensure a good crop of oats. The second year, potatoes or turnip; and for the third and last crop, barley or oats, with grass-seeds, for pasture only.

There are the different classes of soil, with the mode of management, that were proposed to be treated of in this part of the Appendix, as being those which most generally occur. Modifications of culture may be judged of and applied by the occupiers; but the leading object, after draining, is to overcome the barren and unproductive state in which they lie; but not, by *over-cropping*, to exhaust or deteriorate them; and after being managed in the manner described, to let them remain *at rest* for some years, when they will be better able to undergo a more extended course of cropping, and become still more fertile and productive.

GENERAL CONCLUSION.

In the preceding pages, I have endeavored to explain, in as precise and explicit a manner as the subjects admit, the various circumstances, principles, and data on which the 'Art of Draining Land' is founded; as also, the manner of its application in every practicable case; with such directions to guide the execution, as, I hope, will enable every practical farmer to profit by the discovery of the late Mr. Elkington, in the drainage of those more *intricate* cases to which *his system* applies: and also, to apply the more usual modes of hollow and surface draining, which are still very much practised in both parts of the kingdom; and which, in many cases, are the only kind applicable.

Of embankments, I have given a pretty full detail, with practical directions applicable to their various situations, and forms of construction. And lastly, in the preceding Appendix, I have given such hints and directions as may be useful, not to the experienced and more practical farmer, but to those who are not *yet* so fully acquainted with the culture and improvement of *wet* and *unproductive* land, *after* it has been drained.

I have treated these subjects, *in all their various branches*, with that degree of confidence, which the experience of a long and successful practice has enabled me to do; and it will afford me peculiar satisfaction, if this *work* shall contribute, in any degree, to the extension of the knowledge and practical application of these important objects, so likely to promote the interest of the landed proprietor, the farmer and the public in general.

JOHN JOHNSTONE.

Lauriston Lodge, Edinburgh,
December, 1834.

* Though this, in practice, is now almost exploded, it is the best method of subduing such herbage.

From the Cultivator.

EGYPTIAN WHEAT.

This was spoken of, with the other varieties of spring wheat, in our September number, volume iv. Since that time, our attention has been particularly turned to this grain, by the receipt of several parcels kindly sent us, and by repeated inquiries where the seed could be purchased, and at what price. It has also been highly commended in the news journals.

This wheat is known under the various names of *Egyptian, Syrian, Smyrna, many spiked, reed, and wild-goose* wheat. It derives its latter name from a story, which is current in the north, that four or five kernels, from which the American stock has proceeded, was found in the crop of a wild goose, which was shot about four years ago, on the west shore of Lake Champlain. It is called *reed* wheat from the great strength of its straw, which serves to prevent its being prostrated in the field.

The first notice we have of this species of wheat in the United States, is in the 'Memoirs of the Philadelphia Society for Promoting Agriculture.' A parcel of it was received in 1807, by the society, from Gen. Armstrong, then our minister at Paris. This grain was grown five or six years by Judge Peters, and proved to be very productive; a pint of seed, sown in drills and hoed, giving one bushel and a peck of grain. But we find the judge saying, after three or four years' trial, that it had not "thriven so as to encourage extensive culture." In a more *southern* latitude, he expresses a belief that it would do well. It was extensively distributed; but from our not having heard more about it in the last twenty-six years, we believed it had not proven a valuable accession to our husbandry.

We have seen beautiful fields of this wheat. We sowed a sample specimen two years ago, but on being assured by a friend that it was inferior for flour, we gave it up. In the Philadelphia edition of the 'Domestic Encyclopedia,' printed in 1821, we find it stated, that this kind of grain does not yield so much flour or meal as any of the other kinds of wheat, and that "the flour is scarcely superior to that obtained from the finest barley."

Having said thus much, which we felt bound to say in the line of duty, as to the character and introduction of this grain into our country—it remains only for us to add, that the seed may be procured of *our* friend Mr. Thorburn, at *five* dollars a bushel.

REMARKS ON AGRICULTURAL HOBBIES AND HUMBUGS.

We had designed, long ago, to submit, more at length than heretofore, remarks on a class of subjects which may be comprised under the general designation of "agricultural hobbies and humbugs;" to which might be added, "agricultural frauds," if it were not improper and offensive to place in juxta-position the designing deceivers, and the deceived; that is, some of the most knavish of the agricultural profession, with many of the most disinterested, honorable, and public-spirited. But so it is—by the united operations of the cheats and their dupes, (who, being deceived themselves, innocently aid in deceiving others,) there is a perpetual succession, in the agricultural and other papers, of agricultural humbugs and deceptions, by which a few make large profits, and many find disappointment and loss. We have heretofore, though concisely, and as incidental to particular subjects, expressed opinions designed to oppose the progress of this evil; and similar views were more generally expressed by our friend, James M. Garnett, esq. in his last 'Address,' published in this work. Still, there remains an ample field of humbug to treat of, and to expose.

There are various modes of practice, in this branch of business; but the most usual is the following: Some new variety of corn, wheat, or other crop, is announced, and recommended as being superior in production and value, to any thing known before. This statement may be partially true, or altogether mistaken—and in either case, the publication may have been made with honest and praiseworthy intentions. On the other hand, the first motive of the publication, as well as the final effect, may have been to make dupes, and to get hold of their money. According to these, or other circumstances, the early publication either contains, or is afterwards followed by, a notification that Mr. Such-a-one offers to sell seed or plants of this rare and valuable variety, at a price three or four times, or it may be ten times, as high as is usual, or as would be a sufficient remuneration for the raising. The enthusiastic and credulous, among the readers of these highly-wrought panegyrics, are put all agog to obtain seeds which, as represented, alone will add 30 per cent. to their crops. The regular seedsmen hasten to give their orders, that they may profit by the new demand, just as milliners would for bonnets of the latest fashion, and knowing well that the fashion will be as likely to be transient in the one case as the other. The editors and publishers of agricultural journals, who are not themselves seedsmen, find that articles on these wonderful new products are interesting to many of their readers, and very convenient to fill their columns; and therefore, they help on its way every successive humbug, and the more wonderful the account, the more sure it is of being selected for republication. But if the publisher is himself engaged, directly or indirectly, in the selling of seeds, &c. (which is a usual, because a very convenient and profitable combination of trades,) then he can best profit by his readers' appetite for novelties and wonders; for he can not only start and direct the puffs, but such recommendations are, beyond comparison, the most effective of advertisements, because not suspected to be such, nor to be otherwise than the honest and disinterested opinions of the writers. *We*, who have no such connexion with seedsmen or others, and have no such private interest to forward—and who have treated with distrust, scorn and contempt, all efforts to buy of us editorial puffs—yet even *we* can scarcely avoid giving some help to the progress of this widely-spread puffing system; for so many articles in agricultural and other publications partake of this character, without its being apparent, that it is impossible to know all such, and thereby to exclude them from our pages, or to mark them with deserved reprobation, when published. We have always been very scrupulous and cautious on this head; and certainly have never aided, knowingly, any such plan of deception. Still, in selecting for republication the current articles of the day, from other journals, such as notices of particular heavy products, new and valuable seeds, plants, live-stock, and farming implements, we may have been, unconsciously, helping to extend the circulation and effect of a salesman's disguised puff. If we were to discard our scruples, and, instead of neglecting or opposing, were fully to sustain the puffing system, our publication would have many more articles of temporary interest to readers, and in more ways than one, would be productive of much more profit to the publisher.

But this is not all that we suffer from the great and ever-changing demand created and maintained for new seeds, &c. Our remote readers, believing (and very correctly) that we are always pleased to serve them individually, as well as to forward the improvement of agriculture in every department, frequently write to request our aid in procuring for them seed of spring wheat, twin corn, Baden corn, &c. or others of the highly-praised varieties which are successively *elbowing* each other out of notice. We have done our best in such cases, and sometimes at as much gratuitous trouble and expense, as the article in question was worth; even when we had little hope of being successful in the safe transmission; for owing to the difficulties which any one who is not practically engaged in, or acquainted with, commercial business, finds in transmitting articles through circuitous routes, and various conveyances, and by sundry agents, it is probable that not one such venture, in three, reaches its destination safely, after all the trouble and care taken. The regular seedsmen and traders can do better in this respect; and they can not only send any new hobby to any destination, (for price enough,) but moreover, they will generally have a *better* one ready for sale, before the first will have reached its distant buyer.

Since the first commencement of agricultural journals in the United States, there have been many articles announced as new and valuable, puffed into notoriety, thence eagerly sought after by purchasers, tried, and found wanting—and finally abandoned and forgotten. And it is so much more pleasing to mankind to be flattered by vain hopes, and be deceived, than to be warned of the danger of, and guarded against deception, that editors will always advance the popularity of their publications, by floating with the general current, and falling in with every such fashionable error, while it lasts. By thus flattering and ministering to the fancies of the ardent and sanguine, (who are also generally the most zealous and active,) among their readers, *at least to them* they will render the publications most interesting. And though almost every new hobby may, in its turn, be found worthless, yet but few readers will find fault of the favor previously shown. All that the editor has to do, is to dismount, silently and quietly, from the exposed and disgraced hobby, and mount the next one that seems most likely to engage attention and interest.

With such aid, and by such recommendations, the public attention has been at different times solicited to not only various new varieties of the more important grain crops, but also to such minor articles of cultivation, as millet, (of various kinds,) the bene plant, Cobbett's "Russian turnips," (which, as *Swedish turnips*, had been long known, and valued for their real advantages, in England, and treated of in English books, but which it required humbug and false appreciation to bring it into use here—); and as great expectations of profit were thereon built, as are now on spring wheat and the several new kinds of prolific corn; and as probably soon will be, on the Egyptian, or many-headed wheat.

Do not let us be understood as denying all value to these over-rated novelties—nor as wishing to discourage trials of new plants, or new (supposed) improvements of any kind. On the contrary, we would encourage trials, if made carefully and accurately, as being calculated not only to amuse and gratify all cultivators of inquiring minds, but also as sometimes leading to results which, if correctly appreciated, will be of important value to agriculture. But we *do* mean to avow a very general distrust of these many newly discovered values in particular varieties of seeds, &c. and especially when it is manifest that he who makes or sustains the recommendation of the article, has a private and pecuniary interest in raising its reputation, or maintaining for it a high selling price. Let all the attendant and connected circumstances be borne in mind, and the trials be economically, as well as cautiously and accurately made, and we would urge the trial of every new thing that was even plausibly recommended.

In addition to all the supposed more productive kinds of grain, which have been made generally known to the agricultural public, there are hundreds of individual farmers who, silently and privately, cherish their own particular fancies as to the superiority of their own selections. One aims, by selection of seed, to get the *deepest grained* corn, because an ear of such must have much more grain than one of equal size, but shallow-grained; and thence he erroneously infers that the former kind will be much the most productive to the acre. Many, not content with deep grains, seek for the smallest sized cobs—that the larger proportion of each ear may be of grain rather than of cob. On the contrary, John Taylor, our great and distinguished agriculturist, preferred ears with the largest cobs, for seed, because, as is evidently and mathematically true, if the grains are of equal size, there will be more of them encircling a large than a small cob. Some seek for *large* ears; others for *many* ears upon one stalk. Many farmers are as curious and particular in selecting seed-wheat, either for the large size of the grains, the large number of grains in the head, the large number of stalks and quantity of grain from a single seed; and all confide equally in thereby securing more product in general, from the land. Now we have no faith in any of these modes of reasoning, and therefore none in the supposed results. Without denying that particular varieties of plants may be somewhat more productive than others which are equally suitable to the same soil and climate—and admitting that the smallest well ascertained advantage of superiority is worth securing—yet, in general, and in the absence of all positive proofs of exceptions, we maintain that corn, or wheat, or other grains, will produce according to the degree of fertility and mode of cultivation of the soil, and according to the adaptation of the kinds of grain to the soil, climate and season. Perhaps every variety of grain may be the most productive in some particular situation and season; for all varieties are produced by nature, in the never-ceasing effort to accommodate a misplaced plant to its new, and comparatively, inhospitable location or circumstances. It is highly important to adapt the kind of seed to the soil, climate, and usual seasons; and the want of such adaptation may reduce a crop to less than half of what might have been obtained from other seed. But we have not the slightest faith in any of the many prevailing opinions, that larger crops are to be obtained by choosing seed on account of the form, size, or number of grains, or the size or number of ears, &c. Indeed, (as we stated in a former volume, when touching incidentally on this subject,) when ears of corn, wheat, or other grain, are remarkably large, for the particular variety grown, or a single root is remarkably productive, either in number or size of ears, or quantity of grain, it furnishes sufficient evidence of insufficient product from the land; or in other words, that there was too little seed to the acre; and that a greater number of stalks would have yielded a better crop, though by reducing the product of every individual stalk.

These views are not opposed to the fact, that the Maryland twin corn, the Baden corn, or the Dutton corn, (for example) in certain situations, may be more productive than our ordinary kinds. But they are utterly opposed to the belief of either of these varieties, or any other, being more productive in *all*, or in *most* situations—or of being more productive *in a very great degree*, in *any* situation. Mr. Carmichael, who was among the first to recommend the Maryland twin corn, through the pages of the Farmers' Register—and whom we still deem among the best authorities, on account of having full experience and means for observation and comparison—confined his recommendation within the following limits: "My experience" (he says, at p. 605, vol. 2.) "induces me to think that no great advantage is derived if this corn is planted on lands naturally poor, or exhausted by cultivation; but where in a state of fertility, either naturally or by improvements, I think the [increase of] product from this kind of corn will be more than fifteen per cent." Now this amount of increase, if accurately estimated, is sufficiently great to induce the trial of this corn, on the soils recommended as suitable, and in a latitude not very different from that of Queen Ann's county, Md. But this increase is far short of what the sanguine expect, or what would have induced so many to require this kind of grain; and the writer entirely objects to planting it on any but the very small proportion of *rich lands*. This corn is a *forward* kind, even in Maryland; of course it is too forward for our location; and in southern Alabama, and lower South Carolina, it will lose the benefit of near or quite two months of the growing season, which the longer summers there offer to vegetation. This corn will there become, under Nature's correcting training, more and more late in ripening, and the ears larger and fewer; and we believe that Nature knows best how to adapt particular grains to particular soils and climates, and that the more the Maryland twin-corn shall be changed by her efforts, from its present and most highly prized peculiarities, the more productive it will be in southern regions.

Neither do these views contradict others which we have advocated, deduced from the valuable article of Dr. Bronn, in vol. 1, (at page 257) of this journal. Our deductions then made, and still adhered to, were, that northern and moist climates, and clay and cold soils, tended to increase the vegetable (or the stem and leaf) parts of a crop, at the expense of the perfection of the seed; and that southern and dry climates, and hot or sandy soils, made the seed more perfect, but diminished the succulence and size of the plant in general. And, as the first progeny would partake largely of the peculiar qualities of the parent stock, it was therefore proper to bring our grass seeds from the most cold and moist situations, and the seeds of crops, valued mostly for the grain, from the warmest and dryest. We may gain, in this manner, in the particular product most wanting, though at the cost of some general reduction of the product of the entire plant or crop. But, to have a tenth, only, added to the bulk of the stalk and leaf of a clover or other grass crop, wanted for hay, pasture, or green manure, we might well afford that it should be incapable of bringing the half of a usual crop of seed; and we would be very unwilling (by change of seed, or otherwise,) to double our growth of wheat-straw, by lessening the grain only one-tenth. Both these effects, or something like them in degree, we believe might be produced by bringing grass and grain seed, from far northern regions, to be sown in the south; and in a less degree, by changes of seed from cold and moist, to hot and dry soils, on the same farm.

But this is a digression from humbugs and hobbies—or perhaps, as may be charged, from those of other people, to some of our own. We do not claim exemption from the liability of being deceived in such matters, nor, in consequence, of thence aiding to deceive our readers. But we claim *this* at least, that we do not *sell* our humbugs, nor make any pecuniary gain in the humbug market. If we aid in forwarding deception, it is done disinterestedly and honestly. To return then to the subject.

The Baden corn seems now to be the most fashionable and popular variety. The following extracts will show the claims made for it to public favor. The first is a letter from the commissioner of the Patent Office, who exhibits a laudable, though in this respect an ill-directed, zeal for the improvement of agriculture; and the second is the material part of the letter to him from Mr. T. N. Baden, the producer and seller of the corn.

"To the Editor of the Farmer and Gardener.

Patent Office, Dec. 12, 1837.

"Dear Sir—I have received many inquiries respecting the culture of "Baden corn," and addressed a letter to Mr. Baden on the subject. I take the liberty of enclosing his letter for publication in your valuable paper.

"Mr. Baden's experiments this season, show that his own is earlier than many other kinds. I have distributed the last year a great number of parcels of the Baden corn; that which has been planted in latitude not exceeding 40 or 45 north, has succeeded admirably. It will soon be acclimated in the higher latitudes. Over 100 bushels has been raised per acre on the rich lands of the west and south, without any manure.

Yours, respectfully,

H. L. Ellsworth."

"To the Hon. Henry L. Ellsworth,

Washington City.

Prince George's County, Md., Nov. 4th, 1837.

"Dear Sir,—Agreeably to promise, I now write you a few lines to inform you, that within the last two years (and never before) there has been a report in circulation that my corn was a latter kind. However, for the satisfaction of my friends, I have made an experiment this year, which I hope will satisfy every one upon that point. I planted a lot of six acres and a half, as near as I could judge, (by stepping) of this kind of corn, the 20th day of May last—my book is now before me. I cannot be mistaken in the date, which is more than a month later than the common time of many persons planting in this neighborhood. I gave no extra management to hurry its growth, and determined to give it only the common routine of work that I generally give my corn. It is now perfectly ripe and hard, and has been for some time, and no frost could do it any injury in any way; and I believe it will yield as much good sound corn to the acre as any that was planted in the neighborhood any time in April upon land of the same quality. This evidently shows that my corn is a forward kind, and will come to maturity as soon as any other. By the first opportunity, I will send you a few stalks of this corn that was planted the 1st day of May, with the corn on them, as it grew in both the lot and field, and none with less than *four*, and some with *seven and eight good ears on a stalk*—then I will leave you to judge which of them is the better. As soon as it is sufficiently dry to shell and put up, I shall send you twenty or thirty bushels of as good seed corn as you have ever seen. I have not long since discovered something in this corn, which convinces me that I can still make a great improvement on it, by adding much to the quantity and quality of the grain on each stalk. I am now persevering in my efforts, and intend to raise a large crop every year in its purity, to supply all who may apply for it for seed.

* * * * *

"P. S. I can ship any seed that may be ordered each week to Baltimore, if a few days are excepted when navigation is interrupted by the ice."

The grossest, and yet the most profitable fraud that has been practiced, was by an Irishman named Hall, who went through the country (in or about the year 1815,) selling patent rights (as he pretended) for a discovery of his in cultivating corn; by means of which, two laborers only, without horse or plough, and on ordinary land, could make a crop of 2500 bushels of corn, annually. His plan was to lay off a field regularly into squares of nine feet; and one of these squares in each contiguous nine, was to be manured and cultivated, and to bear as many stalks, and (as he promised) was to yield as much product, as the whole space of nine squares, if the whole had been ploughed and planted over equally, as in the usual mode; and each square was to be thus cropped in succession, so as to make a nine-years rotation on the same field. According to his reasoning, the thickly standing corn on each planted chequer, would be benefited by the surrounding vacant eight squares; and yet these eight would be resting and improving, until the turn of each came, in succession, to bear the crop. This impudent impostor did not even exhibit his patent right which he claimed to possess—nor had he any valid testimonials of the worth either of his plan. or his character. His whole means of success consisted in the enormous profits which he promised. It was as if an agricultural Aladdin's lamp had been offered to every farmer. His terms too were very moderate; he asked only $10 in hand, to permit the exercise of his right; and $10 more were to be paid after the first crop had been gathered, and the plan found to be entirely satisfactory. It is true that Hall did not make many converts; but, so far as we heard of his movements, in lower Virginia, he succeeded in making sales to some five to ten farmers in almost every county which he visited during his rapid progress. With these advanced payments he was content; at least he never returned to ask for the much larger balance remaining due. It was still more remarkable, that most of the persons who paid for Hall's plan, were not experimenters, but such as were called "solid, practical farmers." who had been previously eschewers and despisers of all theory and book-farming; and many were old men, who had never before varied from the time-honored usages of their neighborhood. But few of them even tried this dearly bought privilege; for they became heartily ashamed of their bargain before the planting time arrived. Those who *did* try it, made scarcely any crop, and never repeated the experiment.

The merino sheep humbug was of a still earlier date. When the invasion and devastation of Spain by the French served to break up the great merino flocks in that country, and to remove the previous prohibitions to the exportation of sheep of the best breeds, the opportunity was judiciously availed of to supply this country with a truly valuable stock. But the high prices obtained for them generated and nourished a spirit of speculation, such as has been exhibited in sundry other commodities, in various regions and times; as in tulip roots in Holland—lots and lands in and about Richmond, formerly—and lands and sites for future towns in many parts of the western wilderness, recently. The source and the progress of all such bubbles may be stated in a few words. The increased price has no relation to the intrinsic value (or productive use) of the commodity. But whether it be a tulip root or a merino sheep—a vacant and useless lot in a city, or the site of a prospective town in a marsh or a wilderness—the process is the same. The article in question rises in market price (whether by accident, by depreciation of money caused by excessive bank issues, or some other delusion, or by the art of the holders,) say 50 per cent. in a few months. and is sold by A. to B. at that rate of profit. C. buys of B. at a proportional advance, simply because of the rise in price which had taken place, and therefore still expected to advance. Probably he is not disappointed in that expectation; and whether he embarked in the speculation as knave or as dupe, *he* also makes a large profit by selling to D. who is still more eager to buy, that he may not lose his chance for such great profit, the regular advance of which has established confidence in a still continued enhancement of price. Thus the game goes on. The greater and the more rapid the rise in price, the more eager are the buyers; and every one concerned is making large profits—or is made rich, if operating on a scale large enough—until the bubble of speculation can be no more distended, and of course bursts; and the price then is adjusted to *intrinsic*, instead of speculative value. In this way, merino sheep at one time sold in some cases for more than $1000 each. We have before touched slightly on this subject; and expressed the opinion that a like mania was now growing as to race horses, and the improved breeds of cattle.

Another humbug was Mr. Whitmarsh's seed of the Chinese mulberry—which has been fully exposed in the past volume of this journal. The circumstances afford a strong exemplification of the fact, that the public are better pleased to be deceived than to be undeceived; and that if both false promises and means for their correction are presented to readers, that most will grasp at the falsehood, and pass the truth either unnoticed or unbelieved. Before any seed (real or supposed) of the *morus multicaulis* had been offered for sale in this country, we published in this journal, and upon high authority, that these seeds would not produce the parent kind, and therefore were not worth planting. This fact we repeated, and endeavored to enforce, from time to time—but without the notification seeming to have the least effect in preventing error, or staying the frauds of sellers, or the losses of buyers of the seed. The humbug had its course—the sellers made their profit—and now all are content to acknowledge the truth that might have been known as well at first.

The last prevailing humbug is *spring wheat*. Of the value of this newly introduced, or rather re-introduced old variety—for spring wheat is no novelty to well informed agriculturists—we have before intimated our distrust. Nevertheless, hundreds are eagerly seeking seed of spring wheat at $4 and $5 the bushel—and as long as such prices can be obtained, the humbug will live—and no longer. It has already been settled, that *some* kind of this wonderful spring wheat is not worth sowing; but then, it is affirmed that *that kind* was not the "real Simon Pure"—and half a dozen other kinds will be successively offered as the best, paid for at enormous prices, and found alike wanting. Some of the sellers of spring wheat seed are already quarrelling with each other, as to the merits or demerits of their respective kinds, as is shown by the following extracts from late publications.

"*Italian and Siberian Spring Wheat.*—We published in our paper of the 16th instant, a communication from Dr. Goodsell, of Utica, New York, comparing the relative virtues of these grains, and decrying those of the former in no measured terms. Desiring to exercise the strictest impartiality, and at the same time to lay every thing touching agricultural subjects before our readers which in the least interests them, we have published in this day's paper two letters in reply, from Mr. Jay Hathaway, the gentleman who introduced the Italian spring wheat into the culture of this country. Without making ourself at all a party to this controversy, we must express our regret that topics of the kind should be so conducted as to call forth any thing which can be tortured into motives of a sinister character. It is but natural that men should be partial to products of their own; self-love inclines us to the adoption of such opinion; but we can see no reason why one man, who may be satisfied with his own commodity, should step out of his way to attack that belonging to his neighbor."—*Farmer & Gardener.*

The tone of the champion of the Siberian spring wheat, may be inferred from the comments. One of the replies of him who sustains (and is sustained by) the Italian spring wheat, is copied below in full.

"Dr. Goodsell of Utica, has come out in the "Cultivator," (Judge Buel's paper,) strongly recommending his Siberian Wheat, and running down or trying to depreciate the Italian. His letter may possibly hurt the sale of the Italian, where it has not been proven; but in this county, the experience of our whole farming population is against him, and his letter here is quite harmless. Mr. Jos. Wright, a first-rate farmer of this town, has sowed the Siberian three years in succession His first crop was fair—his second was poor—and his third was miserable. I do not certainly know of any other person in this place who has raised it, and it must have very rich land, whereas the Italian does not require it, and will do *well* where the Siberian will not grow at all. The Italian is not liable to rust, let Goodsell say what he will. He is jealous of the fame of the Italian.

Yours, &c. J. HATHAWAY.

The above valuable wheat for seed, may be had (direct from Jay Hathaway, Rome, N. Y.) by applying to John L. Peirce, Bull's Head, North Third-street, Philadelphia, at $4 50 per bushel, by the single barrel. A barrel contains about 3½ bushels.

Philada., Penn., Jan. 23, 1838."

A previous and longer reply in the 'Cultivator,' from Mr. Hathaway, contains the following comparative estimate. The Italian spring wheat is declared to have been raised in "numerous cases, from impoverished lands, that would not yield a crop of oats. *This property alone* should give the Italian spring wheat a name above every other, as no other in this country possesses one so valuable, except such as are in common; none other will grow well, and *produce a good crop upon a poor and worn-out soil,* It has been grown for five seasons in this county, and has not failed in any; it rarely ever rusts, although winter wheat is ruined all around it; it has justly obtained an enviable popularity, as the doctor knows, as a sure crop, a good crop, and a larger;—it is the only article about which there was scarce a difference of opinion, until the letter in question: here it will effect little—abroad it may prevent a million from enjoying a certain good, which unlike the other, has not yet to *establish* a reputation. A "single swallow does not make summer"—nor the yield of a single field fix unqualified by a character. Many folks make wild *guesses:* the doctor says his Quaker friend "*thinks*" that he shall thresh nearly or quite 40 bushels Siberian from one bushel sown. Now this is great, if he has *guessed* truly; yet I can tell him of a man who says he sowed but half a bushel of Italian wheat on an acre of land, and that it yielded him 30 bushels after being threshed, and his account is not *guess* work."

Our inference from this correspondence is, that Mr. Hathaway has already made a pretty penny by *his* spring wheat; and that it is time he should make way for some other public benefactor.

A late occurrence, which will he described as an illustration of some of the foregoing remarks, presented to us, both forcibly and ludicrously, the manner in which humbugs operate.

A highly esteemed and intimate friend, who is a member of one of the learned professions, and no farmer, had lately thrown upon his hands the general direction of a landed estate. Our friend is a regular though cursory reader of the Farmer's Register; and he had been forcibly struck with some of the statements published of the product and great value of spring wheat, which he had seen there, and the far more seducing accounts in other publications; and had not paid so much, if indeed any attention, to our expressed doubts of its value, and warnings against confiding in it as a crop. Under the impressions thus formed, he came to consult us as to a matter of practical farming; and the following was precisely the substance of his statement and inquiry. "There is a piece of ground, of 10 acres on the M——— farm, which was reserved and prepared for oats. It is but of moderate strength, and as I am told, would probably have brought 10 bushels of wheat to the acre, if sown last fall. Now the question is, would it not be the best thing I could do with it, to sow *spring wheat*, instead of oats? I see by advertisements that that grain is selling for seed at $5 the bushel. Now, if I were to buy and sow only 5 bushels on the 10 acres—(so as to make the most of the seed—) and reap only 60 bushels of product—which surely is a *very* moderate calculation—and supposing that my crop would sell for *no more* than $4 the bushel (—for I wish to be sure to be within reasonable bounds—) and still I shall get $22 50 an acre, after paying for the seed."—It did not require much trouble to persuade our friend that his scheme was nought, in regard to his own interest. But perhaps it may not be so, as to the public interest; for the account of it which we take the liberty here to give, may possibly serve to save to some others of our readers fully as much money as he had expected to make by spring wheat. He will be not a little surprised, however, to find himself made use of to oppose the progress of humbugging.

The description, on a previous page, of the Egyptian wheat, however cautiously or correctly stated, is very likely, without any such design, to produce a very general anxiety to possess so curious, and apparently so productive a grain. Indeed, as it is there stated that this seed is already offered for sale, at $5 a bushel, it may be considered that this kind of wheat is already elevated in character to the dignity of a regular humbug; and as such, is launched on its voyage of experiment on the credulity of the agricultural public.

We happened to have known this kind of wheat, having witnessed its growth for two successive years, fully thirty years ago—and its subsequent abandonment, as worthless, by the cultivator. He was not sharp enough to think of such a scheme as offering for sale his last crop at $1 the quart; or perhaps he might have spread the kind through the United States as far as has been done with spring wheat—or as may yet be done with Egyptian wheat itself, notwithstanding this attempt to prevent that result.

The Egyptian wheat (as it was called) which we saw, and observed the after-product of, had several short heads standing out from the bottom of the principal and upright head, which grew as usual with other kinds; the stalk was of strength proportioned to bear so heavy a burthen of grain. According to the usual mode of calculating, in advance, the productiveness of such things, it was supposed that there must be a prodigious increase found in a wheat which bore on each stalk three or four small heads, in addition to one large one. In the earliest sowing, the usual care was taken of the small quantity of seed first obtained; and which care, of itself, serves generally to cause delusion, by showing a very large first product. This seed was drilled, very thin, (so as to make the most of the few seed;) in a garden, on a rich and excellent clay loam. It made two rows, several feet apart, and of some 20 yards in length. The plants were cultivated well, by the hand-hoe, and the growth and product, from so few seed, were considered remarkably fine. The first crop showed *generally* (if our memory is correct,) the valued peculiarities of the kind, in each stalk having several heads. The whole product was sown *broadcast* the next autumn, on a rich part of the field for wheat. The The next crop had none but *single heads*—and exhibited no superiority over the common wheat, so as to induce its being sown again.

The mere novelty of any culture, or, in other words, its being not yet fully tested by experiment, however exciting to curiosity and interest, is but a dubious claim to its being of more worth than other things better known, and already in general use. But even the character of novelty, of many of these humbugs, though forming their principal, if not sole claim to notice, is itself false; for instead of being *new*, they are *old* things which have been tried, and found wanting, long ago, and are again brought forward, because of the general ignorance of any former trial having been made. This applies to both the kinds of wheat spoken of above. Thus, since writing the last paragraph, we found in an old agricultural work, Duhamel's, an account of "Smyrna wheat," which is evidently the "Egyptian;" and making due allowance for the credulity and sanguine expectations of the experimenter, as to its rate of product, it does not differ materially from our own early and almost forgotten experience, as stated above. Having read the whole of this volume some twenty years ago, of course this account did not then escape notice; but it had been entirely forgotten. The volume was printed in 1762; and the experiments made, commenced in 1751. The passage is as follows:

"Smyrna wheat has a very large ear, with several less or collateral ears, growing out of, or round this large one. It requires a great deal more nourishment than the common husbandry will afford; for there its ears grows very little bigger, and produce little, if any, more grain than those of common wheat*. In all probability, it will do much better when cultivated according to the new method [i. e. of being sown in drills, and cultivated]: but the experiments which have hitherto come to our knowledge are very few. The following is the chief, and indeed the only one worth mentioning.

M. Le Vayer, one of the masters of the court of requests, sowed some of this wheat in 1751, in a small part of his estate at Duviere, in the province of Maine, and had a very good crop. He sowed it again in 1752, in the common way; and though it did not answer near so well this time, it yielded him a third more than common wheat would have done."

As to *spring wheat* in general, (which is so entirely new to nearly all who are believers in its superior value,) it is spoken of in numerous European works on agriculture; but by no such authority, that we have met with, is it deemed superior to winter wheat. It is valuable as a substitute, though admitted to be of less value, when the winter wheat has been killed, or could not be sown before winter; and especially in countries, like England, where wheat furnishes most of the bread of the population. Where a so much better spring grain can be raised as Indian corn, we doubt whether any ground remains for using spring wheat, even thus as a substitute. One of the main grounds of the value of ordinary wheat, is, that it can stand the cold of winter, and will produce the more heavily by remaining on the ground through the winter. Oats are not so hardy, and will not generally live through our winters; and therefore we are obliged to sow that grain in the spring. But it is well known, that when autumn-sown oats, *do* withstand the winter's cold, that the crop is far more abundant than any that could be obtained from the same land from spring sowing. It follows, that a kind of oats that could be safely sown in the fall, would be a very valuable acquisition. Winter wheat possesses that hardiness which would cause so much more productiveness in oats; and yet, many are willing to give up that quality, and expect greatly increased products from a wheat which is sown in the spring, because it is too feeble and tender to stand through the winter.

Some wheat of peculiar qualities was introduced from Chili about seventeen years ago, and became a subject of considerable interest to many: but it was found to be a *spring wheat*; and on that account was neglected by all who tried it. *Now*, according to the prevailing views, if again offered, it would be preferred for the very reason for which it was then rejected.

We have referred above generally to English opin-

*Count de la Galissoniere, says M. Duhamel, sowed some of it for several years: it produced a little more grain than common wheat; but the bread that was made of it, was not so good.

sons of spring wheat, and we have just looked for the received opinions of French agriculturists on the same subject. Rozier's '*Cours Complet d'Agriculture*,' &c., it may be presumed, presents a fair exposition of general opinion. In his article on wheat, there are but a few passages on this variety, which, however, show sufficiently that it was valued but little. A version of them will be here given.

"In 1784, I made the trial of sowing spring wheat *(blé de mars)* in autumn; it grew without beard. I have also sown autumn wheat in the month of March, and it became bearded. *May not then this spring wheat be but a degenerate product* (dégénérescence) *of the autumn wheat?* It is known that in 1709, all the wheat in France was entirely killed by freezing; and Louis XIV caused to be purchased in Egypt, wheat which arrived at Marseilles in the beginning of March. It was distributed throughout all the northern provinces of France, to re-sow the land in spring. Much was sown; it grew superbly, and it is from that time known as wheat of March." * * * * *

"Spring wheat has a yellow grain, very short and slender. It also is of two kinds; the one is bearded, the other not; which makes the straw of the latter preferable for food for cattle. This wheat also gives a bread that is too dry; it is necessary to mix rye with it to render it more sweet and palatable." * * *

"As to spring wheat, it is very valuable for lands exposed to the inundations of rivers, during winter, since that kind is not sown but in March."—It is evident that the author would have much preferred autumn wheat, if the peculiar disasters to which the lands were subject, did not render it impossible to sow in autumn with success.

The article of Rozier, quoted from, above, also refers, but in still fewer words, to our other *new-old* acquaintance, Egyptian wheat. This is described as a "yellow wheat, bearing many heads upon the same stalk;" and it is named the "miraculous wheat, or wheat of abundance," which designations are both admirably suited for a humbug; though not its character, as there given; which is, that it is "hard to thrash out, and its flour, very dry and rough, is not good alone, and must be mixed with rye."

We close with the opinions of the excellent practical farmers of Belgium, as to what spring wheat is to be valued for, and the contrary. Radcliffe's 'Report of the Agriculture of Flanders,' furnishes the following passage:

"The heavy rains of the latter season, having made it impossible to sow the wheat till December, and the bad weather which succeeded having injured the clay soil considerably, the growing crop made but a poor appearance.

Upon the defective crops of wheat, the farmer in the month of March was sowing, and covering with the hand-hoe, the *triticum æstivum*, or spring wheat, by which means, notwithstanding the unfavorable weather, he expected to reap a full crop in August.

It seems an important advantage in this species of grain, that, though sown even so late as April, it will ripen at the same time with the winter wheat sown the preceding October. For which purpose, or as a crop in itself, when from bad weather, or any other interruption, the winter sowing has not been accomplished, the spring wheat is esteemed of great value, but is not considered to produce as much, or of as good quality, as the winter grain."

PLAN AND DESCRIPTION OF AN EXCELLENT GATE, AND A COULTER.

To the Editor of the Farmers' Register.

Essex, February 10th, 1838.

Dear Sir—Being always desirous of contributing something (even if it be no more in amount, than "the poor widow's mite,") towards the promotion of our good cause, and of your paper, which is constantly rendering such essential services to it, I now send you two drawings, which I confidently hope, will prove highly useful to our agricultural brethren, in every part of our country. The first drawing represents *a gate*, in the structure of which, I have endeavored to combine all the peculiar advantages that I have noticed in a great variety of gates, which I have carefully examined to ascertain which was best. The second drawing represents a single coulter; for the use of which the season is now rapidly advancing. I hasten, therefore, to send it to you, as I deem it far superior to any, out of five or six kinds of which I have made trial; and indeed, to all of which I have ever seen any description; for it unites strength, durability, cheapness, and simplicity in a greater degree than any of those; while its efficiency is equal to that of the best. All this I may safely say; for it is not my own invention.

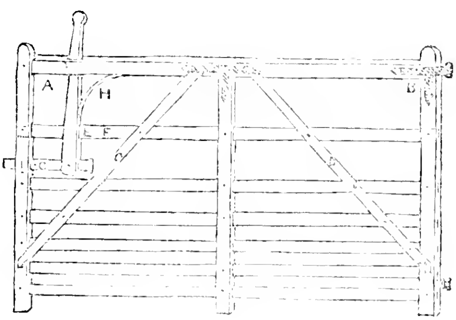
But, before I proceed to my description, permit me to indulge my constitutional infirmity of *digressing*, by inditing you a brief homily, upon what I will take the liberty to call—*The Morals of Gates;* in humble imitation of the illustrous Franklin's "*Morals of Chess;*" a theme, by the way, not comparable, in importance, to mine; for *his* was nothing but a mere game contrived to kill time, whereas *mine* is an invention which has been of the greatest use in rural affairs from time immemorial.

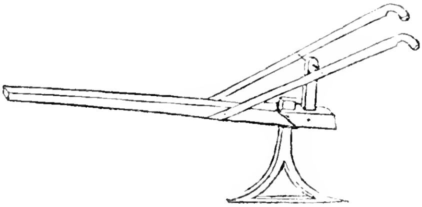
First then, considering the antiquity and universal utility of gates, the rarity of *good* and the frequency of *bad ones*, would hardly be credible, were it not for our daily experience of the fact; although all persons are aware of the numerous evils, that may arise from the latter cause. Among these, it is not one of the least, that even *our characters* often suffer from it, with strangers; for whenever they pass a bad gate, no remark is more frequently made by them than—"*this must be a bad, careless farmer—a lazy, slovenly fellow.*" On the contrary, the sight of a good gate inspires them, at once, with a belief that the owner is a good manager, although, possibly *that* may be the only good thing about his whole establishment. Here the gain is obvious; the means of attaining it so cheap, and the advantage to the proprietor so great, in other respects, that he is inexcusable to neglect them. Again, good gates contribute much to preserve good understanding among neighbors, by preventing the depredations of each other's stock; than which, nothing, in the long catalogue of neighborhood grievances, is more apt to produce bitter and lasting quarrels between those who are bound, both by duty and interest, to live in peace and good will towards each other. Those quarrels are almost inevitable; for the *injurers* and the *injured* rarely ever measure their losses by the same standard, or take the same views of their provocation. Hence, the wrathful indignation becomes mutual—virulent abuse is often reciprocated; until, at last, by such alternate aggravations, this most ridiculous neighbor warfare—originating in no better cause, than a bad gate! is waged with quite as much animosity, as ever inspired two nations to attempt each others' destruction. Let a short recital of one such quarrel, of which I have known several, not materially different, suffice for the rest; and let us suppose, that, on a certain occasion, A's hogs, both seniors and juniors, finding B's gate most invitingly out of order, did, incontinently make a forcible entry through the same, into B's corn-field; and not having the fear, either of God or man, before their eyes, did there most feloniously break down, and wantonly destroy sundry ears of corn, to the great detriment of the proprietor; whereupon, the said B, forthwith issues his mandate to his overseer and negroes, (nothing loth,) to dog, shoot, or otherwise destroy the said marauding porkers. A report of the killed and wounded is speedily made to A, by his people also; made too, with a thousand embellishments and aggravating circumstances, to screen themselves from blame. Then comes A's mandate, as a retaliatory measure, to murder B's dogs; or should *they* not be "come-at-able," to wreak the vengeance, at the first opportunity, upon B's famous high-bred bull, with some great appropriate name, such as Bonaparte, or Jackson. This order being executed, imparts such additional dignity to the quarrel, that it not unfrequently descends to the children, as a valuable part of the family inheritance; and thus may whole families, to the second generation, be kept at variance, for many years—all owing, in the first instance, to a *bad gate!!*

The foregoing arguments and suggestions in favor of good gates, ought, alone to cause every body to make them, who use them at all. But they are susceptible of more important application. They may teach *even politicians*, (high as they generally hold their wise heads above all agricultural matters,) a most useful lesson, thus. When they notice, *as they might*, their perfect adaptation to all the purposes for which they were designed, and plainly perceive that these purposes could not properly be accomplished, unless all their bars and bolts, and braces—their tenons, mortices, dovetails, and hinges—were carefully maintained in their original and relative combinations and positions; might not the said wise-headed politicians apply these manifest facts to our state and federal constitutions? Compared to *a gate*—they are machines of vastly greater importance and complication; although the arguments to prove the necessity of maintaining the relative position of all the different parts of *the gate*, are precisely the same, as serve to demonstrate a like necessity to maintain, unimpaired, the relation of all the parts of our political constitutions; if, indeed, we sincerely desire to preserve them. *Good gates, carefully kept up*, according to the plan of the contrivers, greatly contribute to the neighborly amity, and all its delightful accompaniments of good offices. But *their* sphere of influence is limited to the walks of private life: whereas, *good political constitutions, carefully maintained*, secure peace, prosperity, and happiness, to millions upon millions of human beings, who, *without such restraint*, would have a chance, not much better than that of so many tygers and hyænas, of living together in peace and harmony. If, therefore, any considerations or arguments can possibly be drawn from the former, in favor of the latter, I hope to be excused for making the attempt; especially, when the worst that can happen, will be to condemn *me* as somewhat too fanciful in forcing my premises and conclusions to suit each other.

There is a little story related by Mr. Say, in his excellent work on political economy, so applicable to this subject of *bad gates*, that I cannot forbear to repeat it, in his own words.

"I remember" (says Mr. Say,) "being once in the country, a witness of the numberless minute losses, that neglectful housekeeping entails. For want of a trumpery latch, the gate of the poultry yard was forever open; there being no means of closing it externally, it was on the swing every time a person went out; and many of the poultry were lost in consequence. One day a fine young porker made his escape into the woods, and the whole family, gardener, cook, milk-maid, &c., presently turned out in quest of the fugitive. The gardener was the first to discover the object of pursuit, and, in leaping a ditch to cut off his further escape, got a sprain that confined him to his bed, for the next fortnight; the cook found the linen burnt, that she had left hung up before the fire to dry; and the milk-maid, having forgotten, in her haste to tie up the cattle properly in the cow-house, one of the loose cows had broken the leg of a colt that happened to be kept in the same shed. The linen burnt, and the gardener's work lost, were worth full twenty crowns; and the colt about as much more—so that here was a loss, in a few minutes of forty crowns—purely for the want of a *latch*, that might have cost a few *sous*, at the utmost; and *this* in a household where the strictest





economy was necessary--to say nothing of the suffering of the poor man, or the anxiety and other troublesome incidents. The misfortune was, to be sure, not very serious, nor the loss very heavy; yet, when it is considered, that similar neglect was the occasion of repeated disasters of the same kind, and ultimately of the ruin of a worthy family, it was deserving of *some little* attention." Thus endeth my homily, and now for my descriptions.

The first drawing represents a gate nine feet wide from out to out, by five feet high. The hinder upright or stem is four inches by three. The centre and front stem, are three by two and a half inches. All the bars are three inches wide; but the upper one is square behind, tapered to two and a half inches before. The other bars are one inch thick, at the hinder ends, tapered to five-eighths at the front ends. Each tenon has a shoulder three-fourths of an inch deep; but the shoulders behind should be cut in the *lower* edge of the bars, and those before, in the *upper* edge, as indicated by the dotted lines across the front and hinder stems, where the tenons of the bar, next the top, enter them. These shoulders, thus cut, aid, both before and behind, in counteracting the tendency to *swag*; which is common to *all* gates. This tendency, if not checked, always makes the angle A *greater*, and the angle B *less* than a right angle. The brace C, therefore, acts as a *tie*, while the brace D, acts as a *stretcher*, and both co-operate with the shoulders of the tenons, at the ends of the bars, still farther to counteract the swagging. But the most effectual counteraction of the whole is the upper hinge, which is alike on both sides the gate, and which will suffice of itself, unless the half inch iron bolts, that fasten together by screws and nuts the opposite sides of this hinge, or the hinge itself, should break, which it cannot easily do, if made two inches wide and a quarter of an inch thick. A gate thus guarded cannot possibly swag, while the various guards, eighteen in number, maintain their relative positions. The shank of the lower hinge, should be made an inch or two longer than that of the upper hinge, and the hook on which it hangs should be driven in the post at the same distance beyond the perpendicular line from the upper hook. This fixture, when the gate is opened, throws the lower end of the hinder stem farther from the face of the post, than the upper, and consequently, the gate will shut of itself, if no obstacle interposes. By this simple contrivance the posts may be fixed perpendicularly; otherwise they must incline considerably *inward*, according to the common very unsightly practice. This lower hinge should be about one inch square next the shank, tapered to five-eighths at the inner end, which should have a screw and nut to fasten it. The iron in the form of a T, which fastens the centre stem, the upper bar, and the upper ends of the braces together, by half an inch iron bolts, has a corresponding iron on the opposite side of the gate, and aid in making "assurance doubly sure" against swagging.

The handle of of the latch is two inches wide by five-eigths thick, where it passes through the upper bar; and three by two and a half inches, at the lower end, through which the hinder end of the latch passes, and is fastened in a mortice, somewhat longer and wider than itself, by a wooden pin, smaller than the hole in that end of the latch through which the said pin passes. This is necessary to give it play, and the same difference, for the same purpose, must be made between the size of the hole through the upper end of the handle, and wooden pin which fastens it in the upper bar of the gate. Another mortice is cut through the handle of the latch, at E; also, somewhat longer and wider than the bar on which it plays, and a pin must be fixed in this bar at F, to prevent the latch from being drawn out of its mortice in the front stem, unless the mortice through the upper bar be cut exactly in the oblique direction indicated by the dotted lines across that bar. If this mortice be not thus cut, another wooden pin, in the latch itself will be necessary at G, to prevent it from being forced too far forward, by the spring *H*. This may be made of the thinnest hoop iron, if not bent beyond its point of elasticity; but steel is best. To relieve the latch from friction against the bottom of the mortice through the front stem, a round wooden pin marked I, is driven in, so that half of its thickness shows above the bottom of the mortice, and supports the lower edge of the latch, which should be rounded for three inches, at this part, and then the two surfaces would touch only at a single point.

The foregoing description, may perhaps appear, to some, unnecessarily minute; but, I myself, have so often been puzzled by two much brevity in such matters, that I was determined to err, if at all, on the safe side. In the gate here described I claim nothing as my own invention, but the latch and the upper hinge, which last I have not used, although previous use is not necessary to establish its value.

A very brief description will suffice for the coulter, the original contriver of which, I do not know; for I met with it about two years ago, on board the Rappahannock steam boat, in possession of a gentleman who could give me no other account of it, than that he procured it from the late Mr. George Banks of Stafford county. I was so struck with its manifest superiority to any coulter I had seen before, that I immediately made a sketch of it; had one made as soon as I could; and have been using them ever since, with a decided preference to all others. None, of which I have any knowledge, are superior to it, in any one respect, while this is superior to them all in two important particulars; you may wear out both points, by reversing them, before you send it to the blacksmith; and the point which works behind, causes the coulter to run much more steadily. A single horse will draw it easily in most of our lands, after they have been well broken up with the plough; while four, even of our miserable half-starved Virginia oxen, will break or tear up roots by it, as thick as a man's wrist, with no more "geeing" and "hawing" than they require to drag a load of wood to their master's door, or to any other coulter, that I have ever seen tried.

The lower part of the coulter is made out of inch-square iron, flattened and well steeled at the points, and is twenty-two inches long. The upright part is of bar-iron two and a half or three inches wide, by a half inch or five-eighhts thick, and should be seventeen or eighteen inches high from top to bottom, and left square both on the front and hinder edge. A half inch bolt will suffice to fasten it in the mortice through the beam, which should be at least four by three inches at that part. A band of round, half-inch iron, should also be fixed on that part of the beam, so as to rest against the front edge of the coulter above and its back edge below, which will keep it firmly fixed in the mortice.

If these two drawing, with my description of them, should contribute only half as much as I hope they will, to the benefit of our agricultural brethren, it will be deemed an ample reward, to the end of life by their friend and yours,

JAMES M. GARNETT.

To the Editor of the Farmers' Register.

BUCK-WHEAT CAKES.

By the way of contributing a little to the usefulness of the 'Register,' I will venture to send you a receipt for making buck-wheat cakes. In the room of water, mix up your batter with buttermilk; instead of leaven, yeast, or yeast powder, use a little saleratus, and one, two, or three eggs. If you do not pronounce it the best buck-wheat cake you ever eat, you and I do not agree in taste.

The same receipt is likewise as good for other batter cakes and biscuit. The theory of this is plain, which you will at once see. R.

MARLING AND LIMING IN NEW JERSEY.

To the Editor of the Farmers' Register.

Cumberland, N. J., March 8th, 1838.

Sir—I became acquainted with your 'Essay on Calcareous Manures,' between two and three years ago, by the way of an article in the 'New Jersey State Gazette', copied from the 'New York Journal of Commerce.' I was so well pleased with your theory, as there laid down, that I procured a copy of the essay of Messrs. Carey & Hart of Philadelphia, the first opportunity I had; and I can truly say I perused it with much pleasure, and I trust with some profit. I consider it a valuable work, especially for those making use of marl and lime. I put your 'Essay' into the 'Union Library,' thinking to procure one for myself. I have sent to Philadelphia several times, but could not obtain one at any price. It is perhaps not more than two years since people in these parts generally became in favor of marling and liming. Having got clear of their prejudices, many are perhaps acting in the other extreme. Many people in this county cart marl that contains only thirty or forty per cent of calcareous earth, 6, 7 and 8 miles, and pay for it at the pits from 50 to 65 cents for a load of 20 bushels.

Our practice in this part of the country, generally, is to raise from one to three crops of buckwheat, first, before we sow clover, or try to raise some other grain.

I sowed gypsum last summer on buckwheat, from one to two bushels to the acre. The season was quite wet, and I could perceive but little difference, and none between that which had but one, and that which had two bushels to the acre.

I would like to be informed in the 'Register' or some other way, of your success in using plaster; and whether you still continue to hold to your theory respecting its want of action, as laid down in your essay. I think your theory very ingenious, and far more reasonable and scientific than the old theory respecting the influence of salt water, heretofore maintained by many, without foundation.

Respectfully

CHARLES F. RANDOLPH.

[In answer to the inquiry above, we have to say that there has been nothing found, either in later experience or information, to contradict or oppose the views presented in the 'Essay on Calcareous Manures,' as to the action of gypsum on marled lands; and as to the fact, and the cause, of its not acting on all soils which most need the application of marl or lime.—ED. FAR. REG.]

From the Norfolk Herald.

DISASTERS ON RAILWAYS.

A correspondent calls our attention to a communication in the March number of the Farmers' Register, purporting to be from a correspondent on the Eastern Shore of Maryland, but suspected to have originated nearer home, in which the writer, while arguing against the construction of the Eastern Shore rail road, does injustice, we think, to Major Kearney. But what we regard as more particularly deserving our attention, and the expression of our regret at such remarks from such a quarter, are the notes by the editor of the Register, whose position towards the great body of the public, if we understand it rightly, is one of strict neutrality in regard to all questions of a local bearing. Whatever interest he may feel individually in the line of rail road from the Roanoke to Fredericksburg (and it is natural that he should feel a deep interest in it) it does not become him to make his excellent Register, which owns the whole state for the sphere of its usefulness, a vehicle for advancing one section of it at the expense of another. For instance: he says, "but if experience may be relied on to furnish evidence, it may be safely assumed, that a well managed railway is the safest mode of travelling next to well managed river (*not Atlantic or Chesapeake*) steam vessels." Now this is an assumption notoriously contradicted by fact. Without instituting a comparison between the safety of rail road and steam boat travelling, or between that of *river* steam boats (including those on the western waters) and the steam boats navigating the Chesapeake between Norfolk and Baltimore for the last 21 years, we will only state the remarkable fact, that while the public sensibility has been almost incessantly pained by recitals of "dreadful steam boat disasters" on our rivers, and "accidents and loss of life on rail roads," from all parts of the country, no accident has ever occurred on board of one of the boats running on the Chesapeake, which involved the loss of a single life, or any bodily injury whatever, from their commencement in 1817 up to the present time. Now we defy the editor of the Register, and the whole world to back him, to produce a corresponding instance of exemption from casualty and human suffering on any other line of travel, in so long a period of time. The fact here stated is too well known to travellers, for the inuendo of the Register to cause the least apprehension for their safety in committing themselves to the Chesapeake steam boats.

The editor of the Register also takes occasion in his remarks, to notice the disasters on the Ports mouth and Roanoke rail road, during the last year, in contrast with the great security which has attended the operations of the Petersburg road, which he dwells upon *con amore;* but he says not a word about the recent one on the Richmond and Fredericksburg road. We can state for his information, and that of the public, that the directors of the Portsmouth road have profited by the disasters to which he alludes, so far at least, as to place it in a condition for safety and expedition, not inferior to that which he vaunts of the Petersburg road, and certainly equal to that of the Richmond and Fredericksburg.

The growing popularity of the Chesapeake route, however, cannot be checked by any device, while travellers prefer, as they always do, steam boats to steam cars; for when they have to choose between two routes, the one entirely by rail way, and the other for two thirds of the distance by steam boat, they will assuredly incline to the latter.—[Ed. Herald.]

When it is proposed to reply to, and still more so when to condemn any publication, it is proper, both for fair dealing to the writer, and for the better understanding by the readers of the strictures, that the piece censured, itself, should be presented at the same time. This course we have always desired to pursue, as is done in the present case; and we have never availed ourselves of the customary privilege assumed by editors, of answering an offensive or disagreeable article, before, or without, copying the article itself; and thus, in advance, raising prejudice against it in the minds of readers. We regret that our highly respected brother editor should have adopted a different course; and have done us injury in both these respects, by the foregoing editorial remarks, of his paper of March 30th; and which course is the less excusable, as the entire note, which he considered so reprehensible, is but little, if any, more than half the length of his remarks copied above. Of course, the length did not forbid its insertion. As a matter of sheer justice, we request that he will supply the omission to his many readers who do not see the Farmers' Register, by copying the foot-note in question, from page 752 of the March No., and also, that he will accompany it by these remarks, which his have rendered necessary. They will be made as concise as possible.

First—in correction of mistaken impressions. The *suspicion* that the correspondent who opposed the Eastern Shore Rail Road is not what his communication purports, is as much unfounded, as the expression was uncalled for, in argument, or in courtesy. The writer is a resident landholder and cultivator of the Eastern Shore of Maryland, and one whose private interest in the prosperity of that region, as well as his standing and general intelligence, give him a right to express opinions on that subject, even though they should be mistaken. That his views do not agree exactly with ours, is sufficiently evident to the readers of the notes to his piece, and of several other articles of greater length, which have before appeared in this journal. In reasoning on general and public facts, the name of the writer is not required as authority; and there is no reason why such pieces should not be anonymous. But we assure our brother editor, that we would not knowingly permit a correspondent, were one to attempt such a deception, to *assume false colors*, to sustain private interests either opposed to those which would be inferred from his assumed locality or position, or with which he was desirous to conceal his connexion.

In the next place—we claim for this journal, and its editorial conduct, to the fullest extent, the ground which, it is justly said above, ought to be occupied; but which, it is charged, has been abandoned in the note referred to. In the five volumes of the Farmers' Register, there have been many articles relating to the rail roads from Petersburg, and from Portsmouth, to the Roanoke; and while these two great improvements stood as rival claimants, contending before the legislature, we confess it was difficult, in a journal like ours, open to both sides, and designed to favor the general cause of internal improvement, to appear so perfectly neutral as to satisfy all persons of both the rival interests. But until now, no complaint has ever reached us of having shown less than equal favor and justice to the Norfolk and Portsmouth road and interest; though we have heard of charges of the opposite character, being made by some of our nearer neighbors. These charges had no just foundation; but there is no question, but that more selections, communications, and editorial notices, have appeared in this journal, favorable to the Portsmouth route, and its designed continuations, southern and northern, than to the Petersburg route. The pages and indexes of our volumes offer ready proofs of what is here stated in general.

The views of our correspondent from Maryland, if received as correct, would have operated to lower the true estimation of the safety and convenience of rail road travelling in general, and of the value of the Eastern Shore Rail Road in particular, which route has been planned solely as a most important extension of the Portsmouth and Roanoke Road, and is expected, by the friends of the latter, to give it double value. Now, the manifest object and purport of our note was to defend what was impugned, the safety of rail road travelling; and in that defence, we conceive that Norfolk has at least as deep an interest as Petersburg, and that we were thereby upholding the general interests of the one, fully as much as those of the other.

But we limited our assertion of almost entire security to passengers, to "well-managed rail-roads." Would our brother editor, or our Norfolk friends, have desired that the claim should have been extended to, and made to include the *ill-managed* also? Such a claim would have been as impolitic in argument, as it would have been manifestly false in point of fact. The editor of the Herald does not even dissent, in the slightest degree, from our assertion that the accidents on the Portsmouth road, so fatal in their effects on passengers, were caused by gross mismanagement, and were *not* such as are "necessarily and unavoidably attendant on railway travelling." By maintaining that the causes of these disasters were *not* permanent and continuing, but temporary, avoidable, and that in fact, they *had already ceased to operate on that road*, and that the proper and safe course of management had been there adopted, surely we were *sustaining* instead of *detracting from* the present and future value of the Portsmouth and Roanoke railway.

But the odious part of this branch of our remarks was presenting the case of the Petersburg railway, as proving incontestibly, by long experience, the entire safety of travelling on railways, under proper regulation. This road was not selected for illustration because it is (or is considered as) a rival work to that of Portsmouth, but because we happened to know the facts. Any other road, presenting as strong, or stronger, and as well established facts, would have been as readily noticed. And should any highly improper and dangerous measure be hereafter be adopted on this road, we shall be as ready to denounce it, in advance of the occurrence of its expected ill effects, as to commend what has been heretofore, and is, worthy of commendation. If such reprehension should be necessary, and be ever so sharply given, we shall deem it as *friendly*, instead of *hostile*, to the interest of rail-roads in general, and even of the very road whose conduct is then condemned.

Our little note is not only censured for its sins of commission, but also of omission, in not speaking of a recent accident on the Richmond and Fredericksburg railway. It was not seen then, nor is it now, what bearing that accident, or any other circumstances of that road, had on our designed defence of the safety of railway travelling in general. We know nothing of that road, except from the newspapers, and are not prepared to say whether it furnishes most examples of good, or of bad management. But since we are thus twitted with the omission of instances of the latter, we will add, that if its conduct had been ten times worse than any charged, and the accidents to the trains ten times more numerous than they have actually been, it would only serve to strengthen our previous argument against placing the burden cars *behind* instead of *before* the passengers. For we understand, that by simply avoiding that very faulty arrangement, that all the accidents on that road have been entirely harmless to the lives and limbs of the numerous passengers.

The only remaining charge against our note, is its admitting "well-managed *river* steam vessels" to be possibly safer than even well-managed railway passenger cars; and the denying that greater degree of safety to Atlantic or Chesapeake steam navigation. The former part of the admission, whether correct or not, certainly is not obnoxious to the suspicion of local or private interest. We had especially in view the James River steamers, in which Norfolk is very deeply interested, and Petersburg, scarcely at all. But without claiming the benefit of the limitation to James River, we think that truth demands the admission, and all experience proves, that "*well-managed*" river steamboats are as safe a mode of conveyance as any in this country; and that the numerous and fatal disasters of the *badly-managed*, on the western rivers and elsewhere, afford no ground of contradiction. As to the denial of equal safety to sea steamers, it is enough to refer to the horrible fate of the steamer Home. For the Chesapeake steamers, we readily admit that no loss of life has yet occurred, and have no ground to deny that they are as well constructed, and as well navigated, as any could be. But every bay as well as sea vessel is liable (however small the chance, and remote the danger,) to destructien by water or fire, and steamers particularly to the latter most awful calamity; and if the vessel were about to sink, at only ten miles from shore, having on board, as is usual, twice or thrice, and it might be five times as many passengers as could be crowded into the few boats, the almost certain result would be the swamping of the boats, and the death of almost every passenger. Such a disaster may not occur in a century; perhaps never; but the possibility of its occurring, and the almost certainly fatal results of such an occurrence, must always put Chesapeake, as well as Atlantic steamers, on a very different footing of security from that of the James River steamers.

In concluding, we beg leave to assure the editor of the Herald, that we are not only free from every wish and feeling inimical to Norfolk and Portsmouth, and their interests, but that we should rejoice to see their noble seaport rapidly rising to the elevated station in commerce, population and wealth, for which, by its highly favorable location, and great natural advantages, it seems to have been designed.—ED. FAR. REG.

THE PERSIMMON TREE AND THE BEER DANCE.

(Continued from page 596, vol. 5.)

To the Editor of the Farmers' Register.

When I found my "Persimmon Tree," grouped with the "Persimmon Tree" of James M. Garnett, Esq. in your January No. of the Farmers' Register, I drank his health in a glass of persimmon beer. I am not only pleased with his remarks, but highly gratified that the gentleman has employed his able pen on the subject of this valuable tree. I find very little difference between his opinions and mine, and it rarely happens that two communications on the same subject, accidentally falling together, should correspond in so many particulars. We agree perfectly, as it regards the use and value of the persimmon tree. It will be seen, however, by the reader, that he has discovered an astringent acid quality, in the leaves and unripe fruit, which, when combined with iron, gives a black color for ink. To make amends for this, I have given the medicinal properties of the bark. He has discovered vinegar for table use; to meet this, I have given a good receipt for making beer. He has also informed us, that the wood of this tree makes shoe-lasts; and I have told you, the wood of the persimmon tree makes bed-posts. His molasses and sugar stand ready to sweeten my coffee and tea, and the two communications are so nicely poised and equally balanced, that it is impossible to tell which will kick the beam. I regret, however, that the learned gentleman has obtained brandy by the distillation of persimmon beer; for it may have a very demoralizing effect in eastern Virginia; the brandy drinkers will require such a demand on the product of this tree next fall and winter, that we may lose our sugar, molasses, pies and puddings. Should this be the case, there will, I suspect, be a tumultuous scuffle, and all make a simultaneous movement in order to obtain the great prize. Then, as Jim Black would say, "*the longest pole takes the simmons.*" I am of the opinion, that persimmon beer contains no alcohol, and although it is found in most fermented fluids, I have never witnessed any intoxicating effects from the use of this beverage. Our slaves make it in great perfection, and use it freely without any appearance of inebriation. An old servant in my family was remarkable for making good persimmon beer, and whenever I would pass the door of his house, he never failed to invite me in to taste his beer. "Come, master, drink some beer; simmon beer and ash-cake is equal to *cash*; but it don't make *glad* come like whiskey." Although the old man was a moveable swill-tub as long as his beer lasted, yet I never knew him to be intoxicated. I differ with Mr. Garnett, as it regards the presence of alcohol in ripe fruit. Speaking of the persimmon, he says, "it contains so much of the alcoholic principle as never to freeze." I have been educated to believe, that alcohol is never present in ripe fruit; its components, oxygen, hydrogen and carbon, are not developed or properly evolved, previous to fermentation. Alcohol forms the true characteristic of vinous liquors, and is obtained from wine and other fermented fluids by distillation.

I will call your attention again to the persimmon seed, as a substitute for coffee. It has not the genuine coffee taste, and some individuals may not like it at first; but if they will continue its use, with one-third or one-fourth West-India coffee, they must be pleased with it, and but few can distinguish the taste from genuine coffee. Much depends on parching the seed; they should be carefully stirred with a stick while parching, in order to prevent them from burning, which never fails to give the coffee a bitter taste. Twelve gallons of water, to eight gallons of persimmons, makes the beer luscious, rich and very fine; it may be too brisk and sharp for delicate palates; the beer we generally meet with, has double the quantity of water. Although I am of the opinion that persimmon beer is not intoxicating, yet I have witnessed great glee, and highly pleasurable sensation, produced in our slaves, over a jug-gourd of beer; but I ascribe this reverie or pleasurable hilarity, to the wild notes of the "banjor," which give zest to the beer. There is an indescribable something in the tones of this rude instrument, that strikes the most delicate and refined ear with pleasing emotion; the uninterrupted twang or vibration of its strings, produces a sound as it dies away, that borders on the sublime. I never could account for its wonderful effect on a well-organized ear, capable of distinguishing and appreciating agreeable sounds; unless it be admitted, that concord and discord are so completely blended as to produce perfect harmony. This opinion, however absurd it may seem at first view, is not without its supporters. Pope says, "all discord is harmony not understood."

The honorable gentleman, Mr. Garnett, has indulged in a little innocent merriment in giving us a "Munchausen story"—a "mutton machine," which would really be invaluable if reduced to practice. With all due respect for your valuable columns, I must ask the privilege of being indulged in a similar strain, in giving an account of a "beer dance" that came under my observation.

Some years ago, I rode in the night to visit a patient, and as I passed the house of Mr. Samuel Poe, in the lower end of Prince Edward, I heard the tones of a banjor, and was told by the old gentleman, (Mr. Poe,) that his servants had brewed a barrel of persimmon beer, and he gave them the privilege of having what they called a "beer dance." Curiosity induced me to ride to the door, accompanied by Mr. Poe, and the other gentlemen. And here we saw rare sport! "an unco sight!" Not, however, such a sight as Tam O'Shanter saw when he peeped into "Kirk-Alloway," for the dancers there were "*warlocks* and witches;" here they were Virginia slaves, dancing jigs and clapping "juber," over a barrel of persimmon beer. It occurred to me, that if Tam could have made his appearance about this time on his gray mare *Meg*, the scene would have frightened *Maggie* more than the "*bleeze*" of "Kirk-Alloway;" and Tam might have roared out, "weel done Catty Sark!" a thousand times, and the torch-lights would not have been extinguished.

The ball was opened with great ceremony by singing a song known to our Virginia slaves by the name of "who-zen-John, who-za."

"Old black bull come down de hollow,
He shake hi' tail, you hear him bellow;
When he bellow he jar de river,
He paw de yearth, he make it quiver.
Who-zen-John, who-za."

This was a sky rocket thrown out, as a prelude to the grand exhibition, and will give the reader some idea of what is to follow. Those who could not get seats in the house, took their stand outside, peeping in the door and through the logs, making remarks on the dancers; and here I will observe, that there was a complete Babel jargon, a confusion of tongues!

"Down the road, come show me de motion." "Set to your partner, Dolly."—"Cut him out, Gabe."—"Sal. *does* put her foot good."—"Yonder come de coal-black horse."—"The yellow roan's up! hear how he lumbers! he's a *reel* stormer, ring-clipper, snow-belcher and *drag out*."—"Congo is a *scrouger*; he's up a gum, and no bug-eater I tell you; he carries a broad row, weeds out every thing—hoes de corn, and digs de taters."—"Molly look like kildee; she move like handsaw—see how she shake herself!"—"Hello! in there, I wish you all sen' us out some simmon beer." "Lor! see how Aggy shake her foot! she *ken* pull the whip-saw down."—"Nick? come here and see Ben cross hi' bow-legs! look at hi' mouf! when he grin, hi' mouf' and teeth like hen-ness full o' eggs."—"Nick? I reckon if Tamar's cat stay in there much longer, they will mash her guts out; her skin '*ont* hold peas."—"Come here, Gabe; come, if you please; Jackson's Dick is dancing with Ellington's Nance! see how she quivers! *Now*, Nance!—*Try*, Nance!—She *does* but look pretty.—When she sets and turns, she is like a *picter* —and she is fine form, back. Dick shan't have Nance; I'll kick him high as the meat house first." [Sings.] "She *bin* to the north, she *bin* to the south, she *bin* to the east, she *bin* to the west, she *bin* so far *beyond* the sun, and she is the *gal* for me."—"Dick hadn't no business dancing with Nance; he ain't a man of *gumption*. I tried him, and he can't be made to understand the *duramatical* part of the function, the function of the fundamental, and the *imperality* of ditrimental things. Gabe? Dick's a fool, and you may tell him Sambo says so: he is knock-knee'd, and ugly enough to eat *Gumbo*." "Well, I know that; sing on Sambo."

"I went from the great-house, down to the kitchen,
To get a knot of light-wood to see to go fishing,
To treat granny Di: a;

I went to the stable, I cotch master gray horse,
I clap the saddle *pon* him and he trot like *do'nk* care.
He *do'nk* care, he *do'nk* care.

Having become tired of this out of door conversation, we concluded to view the group in the house. Here the banjor-man, was seated on the beer barrel, in an old chair. A long white cow-tail, queued with red ribbon, ornamented his head, and hung gracefully down his back; over this he wore a three-cocked hat, decorated with peacock feathers, a rose cockade, a bunch of ripe persimmons, and to cap the climax, three pods of red pepper as a top-knot. *Tumming* his banjor, grinning with ludicrous gesticulations and playing off his wild notes to the company. Before him stood two athletic blacks, with open mouth and pearl white teeth, clapping *Juber* to the notes of the banjor; the fourth black man held in his right hand a jug gourd of persimmon beer, and in his left, a dipper or water-gourd, to serve the company; while two black women were employed in filling the fire-place, six feet square, with larded persimmon dough. The rest of the company, male and female, were dancers, except a little squat wench, who held the torch light. I had never seen Juber clapped to the banjor before, and you may suppose I looked upon such a novel scene, with some degree of surprise. Indeed I contemplated the dancing group, with sensations of wonder and astonishment! The clappers rested the right foot on the heel, and its clap on the floor was in perfect unison with the notes of the banjor, and palms of the hands on the corresponding extremities; while the dancers were all jigging it away in the merriest possible gaiety of heart, having the most ludricuous twists, wry jerks, and flexile contortions of the body and limbs, that human imagination can divine.

"The whole world is a ball we find,
The water dances to the wind;
The sea itself, at night and noon,
Rises and dances to the moon.

The earth and planets round the sun,
Still dance; nor will their dance be done,
Till nature in one blast is blended:
Then may we say the ball is ended."

The rude ballad set to Juber, corresponds admirably with the music and actors in this wild fantastic dance. While the clappers were laboring in the performance of their office, they responded at the same to the notes of the banjor.

"Juber up and Juber down,
Juber all around de town,
Juber dis, and Juber dat,
And Juber roun' the simmon vat.
Hoe corn, hill tobacco,
Get over double trouble, Juber boys, Juber.

Uncle Phil, he went to mill,
He suck de sow, he starve de pig,
Eat the *simmon*, gi' me de seed,
I told him, I was not in need.
Hoe corn! hill tobacco!
Get over double trouble, Juber boys, Juber.

Aunt Kate? look on the high shelf,
Take down the husky dumplin,
I'll eat it wi' my *simmon* cake,
To cure the rotten belly-ach.
Hoe corn! hill tobacco!
Get over double trouble, Juber boy Juber.

Raccoon went to *simmon* town,
To choose the rotten from de soun,
Dare he *sot* upon a sill,
Eating of a whip-poor-will.
Hoe corn! hill tobacco!
Get over double trouble, Juber boys Juber."

When supper was announced, the banjor-man, was first served; then the clappers and beer bearer, and lastly, the beaux and their partners. Each had a huge loaf of larded persimmon bread with a gourd of beer.

Thus ended the beer dance, and as I left the house, I thought to myself, that Virginia slaves, were the happiest of the human race—and I still think so.

"The learn'd is happy, nature to explore,
The fool is happy that he knows no more."

Solomon the wisest man, says—"in much wisdom, there is much grief: and he that increaseth knowledge, increaseth sorrow."

The beer dance, I have attempted to describe, is a faint representation of what actually occurred. It requires an abler pen to it justice; I feel mortified that I cannot give a more vivid and glowing description of these black beaux, who acted so conspicuous a part with their partners in the persimmon junket. The broad grin, the smile of the little squat wench, seen through her torch-light, the humid lip, the twist of the tongue, the white teeth, the oblique look, the glance of the eye, the toss of the head, the quaint bow, the curved shin, the bandy leg, the nimble jig, the affected air of the wenches, the profuse perspiration, the cloud of dust, the lurid room, the phiz of the banjor man, the banjor's *tum, tum, tum*, and Juber's song and clap, would call forth the combined talents and lively imagination of a Wirt, an Irving, a Burns, an Addison, and Dryden. And if a northern abolitionist, with his pocket filled with inflammatory documents and resolutions, could have witnessed such a scene in Virginia, he would, in my opinion, have consigned them to the flames; his great love for the blacks, to the contrary notwithstanding.

In conclusion, I offer no apology for introducing in your columns, and bringing before your intelligent readers, such a novel, rude production, as the *beer dance*. We are to derive from such scenes in this life, much useful instruction; the poet, divine, statesman, philosopher, and all mankind, may be benefited by looking *down* in life, in order to explore the dark corners of nature.

There is this consolation to be derived from the scene I have described; the pleasing recollection that God has placed us high in the scale of human beings; and we should all appreciate its worth.

I drink you the following sentiment, in a glass of persimmon ale: May the product of the persimmon tree, substitute foreign wines, molasses, sugar, tea, and coffee, and save the "old dominion" thousands annually.

With sentiments of regard, and esteem, I am,
Your obedient servant.
WILLIAM B. SMITH.

REMARKS ON THE PUBLICATION OF 'JOHNSTONE'S TREATISE ON DRAINING, EMBANKMENTS, &c.'

In this number is completed the general 'Treatise on Draining, Embanking, &c.' It was contrary to our intention and desire that this republication should be divided between two of our volumes. Nevertheless, the subject treated in each volume is entirely distinct and independent of the other; the one being on draining in all its branches, and the portion here presented embracing all that relates to embanking low lands straightening water-courses, and constructing dams, &c. This latter portion is valuable not only in a very important degree for agricultural improvement and profit, but even more, at least in this country, and in these times, to civil engineers, and to all other persons who, without the knowledge possessed by engineers, undertake the construction of dams, making canals, straightening of rivers, and other such works. In the *improvements* (so often miscalled,) of rivers for navigation, in this country, millions of dollars might have been saved, if merely the theoretical principles, and practice, presented in this number had been known, and properly regarded, by the constructors.

The republication of this work, in the Farmers' Register, besides causing a very heavy pecuniary cost for engravings, &c. has produced delay and disorder in the heretofore very regular times of publication, and also other important difficulties in our mechanical operations. But a small part of these disadvantages (the irregularity of publication,) has fallen upon our readers; and we hope and believe, that there is not one of them, whather he be farmer, civil engineer, mill-owner or mill-constructor, or merely a general reader, who will not find ten-fold remuneration in the information and instruction afforded by some portion of the contents of this treatise, which is now, for the first time, offered to the view of American readers.

The English copy of this work, which this first American edition gives in full, cost $6 in purchase money, as imported by our special order; and which is lower than it could be sold for, even if there were any other English copies in America, which is believed not to be the case. The subscribers to the Farmers' Register get this reprint, which gives every word, and every illustration, of the original work, (though, of course, in inferior style,) for 57 cents; that being the proportion of $5, equal to that which this treatise occupies of the bulk of one volume of the Farmers' Register.

For the Farmer's Register.

COMMERCIAL REPORT.

There is less demand for every description of imported goods this spring, than there has been in any previous one for many years. Small as the importations were, they are sacrificed at less than cost in the northern markets. Merchants from the south and west cannot make collections, and consequently have no means of purchasing. But even if collections could be made, the difference of exchange is so great, even where northern funds can be procured, as to deter men of business from carrying on their accustomed transactions.

In Virginia, 5 to 6 per cent. premium is paid on New York; and in New York, western paper is 20 to 30 per cent. below par. Sterling bills on New York are at 4 to 5½ per cent. premium; or, taking specie as the standard, 4 to 5 per cent. below par. Such a state of exchanges never before existed.

The south-western banks have become the principal purchasers or shippers of cotton, so that the merchants are almost completely thrown out of the business. The price of cotton is higher in the towns on the Mississippi and Alabama, than in New York. In the latter it is 7 to 10 cents; in the former, 8 to 11. The rate of freights is higher than at any time since the termination of the last war.

In our own markets, cotton is in fair demand at 8½ to 9½ cents. Not a vessel for Europe was in port during the month of March.

Tobacco is in demand at prices nearly or quite double those of last year, for the lower qualities, and 50 per cent. higher for the better sorts. The range of quotations is $3.50 to $12. This advance is owing to the diminished stocks in every market; the crops of Virginia having been small for the last two years.

Flour commands $7.25. Indian corn 70 cents. Of wheat, there is none brought to market.

The New York and Boston banks propose to resume specie payments next month. A convention of the banks generally, is to be held in New

York a few days hence, when the time for general resumption will be proposed; but that it will be at an early date is not expected. X.

April 7.

From Loudon's (London) Gardener's Magazine.

JOYCE'S NEW MODE OF HEATING.

Mr. Joyce, a commercial gardener at Camberwell, has recently made one of the most extraordinary inventions for producing heat, which have ever been given to the public. We question if any thing so remarkable has occurred, in a practical point of view, since the *invention* of gunpowder. Whether Mr. Joyce's stove will be so economical as to be adapted for general use, is a question that can only be satisfactorily determined by experience; but in the mean time it promises to be so; and, while it may be employed to heat churches, and all kinds of public and private buildings, ships, and the inside of carriages, Mr. Joyce thinks that the poorest cottager will find more comfort and economy in its use than in the common open fire-place. The invention not being, at the time we write, fully secured by patent, the details cannot be here given; but the result is, that heat is produced by an apparatus of very limited magnitude, and that it may be raised to any temperature that can be required, short of red heat, by combustion without the production of smoke. To most of our readers this will seem impossible; but the fact was placed beyond a doubt yesterday (Dec. 5), when one of Mr. Joyce's stoves, in action, was exhibited at a meeting of the Horticultural Society, in Regent Street, and examined by a great number of persons. The form of the stove in which the heat is generated, is that of an upright cylinder, from the conical apex of which a heated current of air escapes, and which current can be regulated at pleasure, or altogether stopped: but the chief source of heat is the radiation from the sides. Of course, the heat so generated may either be allowed to escape directly into the surrounding atmosphere, or be conveyed away in air-tubes, or by means of hot-water pipes, to a distance, or to any other apartment. If this invention answer the expectations which have been formed of it, it will effect a complete revolution in the mode of heating dwelling-houses throughout the world; because it is the only mode hitherto discovered by which heat can be produced by combustion, without any heat being lost. At present, whether a room is heated by an open fire-place, a close stove, steam pipes, or hot-water pipes, or by the introduction of a current of heated air from a cockle-stove, still a large proportion of heat necessarily escapes along with the smoke produced by the consumption of the fuel; but here not one particle of heat escapes, and the only care requisite in regard to the air of a room will be, to have a quantity of fresh air admitted proportionate to what is deteriorated by the combustion of the material employed in this new mode of heating, and by the persons breathing in the room. One advantage attending this invention is, that it is perfectly free from dust, and that the stove, when once charged and lighted, requires no attention whatever for from 20 to 30 hours, according to the charge. The convenience of such a mode of applying heat to rooms, without fire-places, closets of every description, whether of books, curiosities, or plants, &c., and, in short, to all enclosed places without chimneys, must be obvious. It is also adapted beyond all other inventions, for heating, with security from fire, ships, and for warming the inside of close carriages; and it might be taken under water in a diving bell, or into the atmosphere in a balloon. It is also admirably adapted for the purposes of French cookery. We shall not, however, enlarge farther on this invention, till we can explain to our readers what it is; and this Mr. Joyce has kindly promised to enable us to do at the very earliest moment after his patent is sealed. It is no small honor to the profession of gardener, that an invention of so much importance has been made by one of their number.—*Conductor.*

From the same.

Joyce's new stove and economical fuel.—Since we noticed this stove in our former number, p. 57, Mr. Joyce has taken out a patent, and has formed a partnership with Mr. Harper, of Cornhill. The stove has been exhibiting to the private friends of Messrs. Harper and Joyce, and to some literary and scientific men, three times a week; and it has been noticed in the 'Mechanic's Magazine' and the 'Literary Gazette,' for January 13, the only public journals, as far as we have observed, that have noticed it at all, except this Magazine. The following are extracts from the notices referred to:

Joyce's new stove "is in the form of a tall urn, having a pipe running entirely through the centre, with a cap or valve at the top, to regulate the draft. The urn is of thin bronze, and about two feet high, and eight inches in diameter. By the combustion of the fuel inside, the metal continues at a dull red heat, and so gives off the caloric to the surrounding air. The fuel is stated to be a vegetable substance; and one charge, in a stove of the above described dimensions, will burn for thirty hours, and will cost 6*d*. No smoke or effluvia are produced.—*Mechanic's Magazine*, January 13, 1838.

"*New mode of heating rooms.*—The puzzle which has been shown at the Jerusalem Coffee House, has set the wits of conjecturers at work upon the nature of the particular fuel, which, at so cheap a cost as a farthing an hour, is to warm a room. Of these conjectures we have heard two. The first is, that the gardener who discoved the fuel, which enabled him to keep up the fire whilst he slept, must have used old tanner's bark, as it was the only fuel accessible in a hot-house. The other is, that charcoal is the base, and lime employed to absorb the carbonic acid gas. Gipsies are in the habit of using the ashes of their fires, raked together in a heap, and sprinkled with lime. This will burn throughout the night, and no deteriorating gas is evolved to distress the sleepers in the gipsy tent."—*Literary Gazette*, January 13, 1838.

Mr. Joyce's patent is dated December 16, 1837; and the time for giving in the specification to the patent office, is limited to six months from that date. It will not be before our July number, therefore, that we can make our readers acquainted with the secret of the kind of fuel and the mode of burning; but, in the mean time, we may state that the conjecture as to the fuel consisting of charcoal and lime, which was made by Mr. Sylvester, the engineer, in the Horticultural Society's meeting-room, when the stove was first exhibited there, is by far the most plausible.

NEW CONDITIONS OF THE FARMERS' REGISTER.

The price reduced for the current and back volumes, and a further reduction proposed for the next.

I. The Farmers' Register is published in monthly numbers, of 64 large octavo pages each, and neatly covered, at $5 a year—payable in advance. Or three NEW subscribers, by sending their names and $10 at one time to the editor, free of postage, and of every other deduction from the amount, shall receive their copies *for one year*, for that sum, or at $3.34 for each. Purchasers of any three volumes (except Vol. I.) at one time, in like manner, shall have them for $10. [This reduction of price will be made on all suitable orders dated after April 20th.]

II. The risk of loss of payments for subscriptions, which have been properly committed to the mail, or to the hands of a postmaster, is assumed by the editor. ALL MAIL PAYMENTS MUST BE MADE IN NOTES, OR CHECKS, OF PAR VALUE IN VIRGINIA; and these, and all other letters, (except such as contain articles for publication,) must be POST PAID.

III. For all copies not received by mail, at the proper post offices, duplicates will be furnished to those subscribers who have complied with their own obligations; provided that the failure shall be notified through the postmaster, and within two months after the date of the miscarried copy.

IV. If a subscription is not directed to be discontinued before the first number of the next volume has been published, it will be taken as a continuance for another year. Subscriptions must commence with the beginning of some one volume, and will not be taken for less than a year's publication.

V. The mutual obligations of the publisher and subscriber, for the year, are fully incurred as soon as the first number of the volume is issued; and after that time, no discontinuance of a subscription will be permitted. Nor will a subscription be discontinued for any earlier notice, while any thing thereon remains due, unless at the option of the editor—(or in obedience to the regulations of the Editorial Convention, copied below.)

VI. Any five *old* subscribers, by paying for any current volume $20 *directly to the editor, at any one time before the issue of its second number, and without causing any charge for postage or agency*, shall be credited for their five copies for the year so paid for—thus reducing the price to $4 for each. This privilege, of course, ceases, for each volume, as soon as its 2nd number is issued—and no subscriber can use it, *who is indebted for a previous year*, unless his arrears are paid at the same time.

New Condition, offered for the 7th volume only.

Each subscriber to the Farmers' Register, for the present (6th) volume, (or any person who may hereafter subscribe for it,) who has paid for the same when the proposed arrangement shall take place, may, *by sending the names of three new subscribers*, for volume 7, at any one time previous to January 1, 1839, accompanied by a POST-PAID *current bank note, or check for ten dollars*, shall have credit for his own payment for volume 7, in addition to that for the three new subscribers; the *four copies, of that volume only*, being thus supplied for ten dollars.*

General Regulations adopted by the Editorial Convention.

The following resolutions of the Editorial Convention of Virginia, will hereafter form part of the conditions of the Farmers' Register, and will be strictly observed.

1. "All subscriptions shall hereafter be considered as incurred and due in advance, and for a year's publication, unless specially ordered for a shorter time, and paid for in advance for that shorter time, when so ordered.

2. "No publication shall be sent to the order of any new and unknown subscriber, unless paid for in advance, or satisfactory reference be made to some known and accessible person in regard to the subscriber or his payment. But, in case of an order for a publication, without payment, from a new subscriber who is unacquainted with the conditions, a single number may be sent, containing, or accompanied by, a copy of this regulation.

3. "The names of all subscribers, whose ability to pay may be unknown to the publisher, and who may remain indebted on open account at the end of two years, from the time when the advanced payment was due, shall be erased from the list of subscribers." [*Resolutions of the Editorial Convention of Va.*

Address— EDMUND RUFFIN,

April 12th, 1838. *Editor of Farmers' Register, Petersburg, Va.*

* For reasons which will be hereafter stated, it is designed to conclude the present volume on December 31, 1838—by issuing two numbers in advance of the regular times of publication. Therefore, the next and succeeding volumes will begin with the year. This change of time will be convenient in many respects, and is especially required for an agricultural journal.

TO THE FRIENDS AND SUPPORTERS OF THE FARMERS' REGISTER.

The attention of every subscriber and friend to the Farmers' Register, is requested to the new alterations, and temporary additional article, in the general conditions of publication; and as many as can, with convenience, avail of the advantages offered by the latter, are requested to do so, not only for the benefit of the individuals concerned, but for the purpose of extending the circulation and the influence of the work, and thereby greatly increasing its useful operation. It is believed that almost every subscriber now on the list, might, with the inducements thus offered, obtain at least three new subscribers among his neighbors; and those who deem and declare the present and previous operation of the Farmer's Register to be highly beneficial to the improvement of agriculture, have still stronger motives to urge to the effort; and they can well estimate the increased benefit to the public, thus to be obtained by a quadrupled publication and distribution of the work. We should rejoice at reaching such a general result, even though the nett profits were not to be increased in the least thereby.

The expenses of printing, however, decrease still more rapidly than the amount of sales of a publication increases by a greater demand; and therefore, we shall not lose any thing by any extent of the use of the privilege now offered. And if this abatement of price should finally serve to give a list of subscribers increased four-fold, then that which is now offered as an experiment of a temporary measure, of special and limited application, may safely be made permanent and general, by reducing the price of the Farmers' Register to a lower rate than any publication, of worth or character, has ever yet been offered in the southern states.

If by the legislative action of any state, or of any public spirited association of individuals, a sufficiently large sale of this work was guarantied to the publisher, the price might be reduced, for that state, to but a little more than double that of as much blank paper; and when the sales were once made equal to so large a supply, of this or any really useful agricultural journal, the demand would doubtless continue, at so low a price; and the sustaining aid of public patronage, as security against loss, would no longer be required. It is doubtful whether any other mode of extending the knowledge, and the improvement, of agriculture, would be so effectual and so cheap. But this, or any other legislative aid to agricultural instruction and improvement, is out of the question, at least in Virginia; and therefore the experiment now proposed, appeals to individual interests, and has regard to the action and patriotism of individuals only.

It is indispensable for those who mean to benefit the publication and themselves, as well as the agricultural interest in general, by making use of this offered privilege, that they should do so before the close of volume 6; as the increase of number of the copies of volume 7 must be then determined on, and cannot afterwards be altered. It is to allow full time for the usual slow movements of subscribers that this early notification is made.

Should this offer prove acceptable to a large number of our present subscribers, it will have other very beneficial results, in causing payments to be made prompt and certain, and relieving the publication of the present heavy expenses of commissions paid to collectors, postage on remittances, and most of the many and total losses of debts for subscriptions. These several items, in distant places, and where the subscribers are few and widely dispersed, consume nearly the whole profit of those subscribers, similarly located, who are both punctual and generous patrons.

It is hoped that no person who may choose to avail himself of the proposed reduction of price, will forget that the very foundation on which it rests, and by which alone it can be afforded, is that, in relation to all such subscriptions, the publication is to be entirely relieved of all expenses and losses of postage, exchange of uncurrent money, and every other charge, save the furnishing the work according to the 'General Conditions' of the publication. According to those conditions, the loss of money remitted by mail, in these as in other cases, is still at the risk of the publisher, and all numbers of the work, lost by mail, are to be re-supplied—both losses being duly authenticated, as required in the general conditions annexed.

Any subscriber who may have paid in advance for volume 7, may still have the benefit offered above, of four subscriptions for $10, except that his second payment, so included, will be placed to his credit either for another copy of volume 7, for some other named new subscriber, or for any other back volume (except vol. 1,) for himself, as he may choose and direct, at the time of sending the order.

Vol. VI. MAY 1, 1838. No. 2.

EDMUND RUFFIN, EDITOR AND PROPRIETOR.

NEW DISCOVERY IN MAKING MANURE.

To the Editor of Bell's (London) Weekly Messenger.

Corner of Half-Moon Street, Picadilly, London, December 30, 1837.

Sir—I beg to hand you a copy of a prospectus relative to a new manure, which I drew up in the course of last spring, by the request of the Earls of Leven and Melville, from the Report of the Committee of the Academy of Agriculture at Paris, and from the certificates given to the inventor by thirty-eight large landed proprietors in France, testifying the value of his invention.

Lord Leven considered, and in which opinion I had the honor to concur, that the best mode of giving the benefit of the discovery to the British farmer would be, for a committee to be formed for the purpose of collecting a subscription sufficient to defray M. Jauffret's expenses to this country, for the purpose of his making experiments before some person appointed for the occasion.

That an agreement should be entered into with M. Jauffret, that should his invention answer the description given of it, that he should communicate the secret by which he effected the operation, for a sum of money previously agreed upon, and that experiments should be made with the manure under different circumstances, as to soil, &c. to ascertain its relative value with regard to other manures, taking all things into consideration. I have the honor to be, sir, your very obedient servant,

HUMPHREY GIBBS,
Honorary Secretary of the Smithfield Club.

Prospectus of a process for obtaining cheap and valuable Manure, without the aid of Cattle, invented by M. Jauffret, of Aix.

A method has been discovered in France, of making manure as it may be wanted, without cattle, in twelve days, and with great economy, as appears from a report made to the committee of the Academy of Agriculture at Paris, by M. Chatelain, its secretary, who, with M. Cailleau, president of that committee, M. de la Gerandiere, president of the Academy of Agriculture of Blois, and the Marquis de Saint Croix, were appointed to examine into the merits of M. Jauffret's invention.

These gentlemen report "that by a cheap wash or lye, the ingredients of which are to be found in all places, and which every cultivator can make on his own land, all sorts of herbaceous and ligneous substances, such as heather, furze, brambles, and even the living dogstooth, can be put into a state of rapid fermentation, and not only these substances, but even earth itself, be its nature what it may, can be converted into a valuable manure.

"That the manure produced by this new system, is quite as valuable as the best horse-litter; its effects are visible upon several successive crops, and it can be obtained with perfect facility, at pleasure.

"That M. Jauffret supplied the committee with numerous and undeniable proofs of experiments, ranging over a period of nine years, in five communes of the department of the Bouches-du-Rhone, in which trials were made upon an extensive scale, on different kinds of soils, and on various seeds, plants, and trees. The success of those trials surpassed the most sanguine expectations, as has been attested, 1st, by the Academy of Aix, (annual public session 1835, at 38 and following pages of the 'Report'); 2d, by the circular of the prefect of the Bouches-du-Rhone; 3d, by 38 certificates* from most respectable inhabitants and farmers of that department, founded upon repeated experiments made by themselves; and 4th, by the declaration of well-informed proprietors of the department of Vaucluse, who for years have attentively watched the trials of the Jauffret manure.

"That in order to convince themselves more thoroughly on the subject, the committee wrote, unknown to M. Jauffret, to some individuals who were most distinguished by their agricultural science, and who had given certificates to the inventor, and that their replies, which are annexed to the report, are of so satisfactory a nature, as to leave no doubt on the minds of the committee of the importance of the discovery.†

* A printed copy of these certificates may be seen at Messrs. Thomas Gibbs & Co., seedsmen and nurserymen to the Hon. Board of Agriculture of England, and to the Board of Agriculture of Sweden, corner of Half-Moon street, Picadilly, London.

† Mons. Gauthier de Vancluse, who is about to publish a new Atlas of Agriculture, says, (in print at Marseilles, 1832) "M. Jauffret, an intelligent farmer and acquaintance of mine, possesses exclusively the valuable power of converting, in less than a week, all vegetable substances, whether dry or not, into dung of good quality, without spreading them as litter, or even submitting them to the tread of cattle. The change is effected, as if by enchantment, by means of a lye, with which he sprinkles the straw, herbs, leaves, plants of all kinds, even woody stalks of a finger's thickness, previously dividing them to a certain extent by a very ingenious operation. Such is the action of the lye, that forty-eight hours after the matters are heaped, their fermentation becomes, as it were volcanic; volumes of smoke announce the decomposition at a considerable distance; and a poor and spent soil may, without delay, receive, in the form of an excellent manure, that which a week before could have done nothing towards rescuing it from a state of exhaustion."

Like all other interesting discoveries, this has been the subject of fierce attack; but experience has vindicated the inventor. Following the example of many landed proprietors, I determined upon making trial of this important manure, and I declare it equal to that of well-fed horses. M. Jauffret asserts that he can at pleasure increase the dose, and even confer all properties required by the nature of the soil on which he uses it.

One single horse-cart load of straw, or other dry material, produces more than two of good dung. The inventor charges 5 francs (2s. 6d.) for each cart load; probably, to those who should effect the operation themselves, the expense would be diminished by one-half.

The advantages of such a process are incalculable.

"The committee enter into the following details of the process:

"By means of a cutting machine, the cost of which is about 600 francs (£15), and which, after a careful examination, appeared well adapted for the purpose, three men and a horse can prepare 180 quintals, or 7,200 kilograms (about seven tons English) of manure per day, and the machine is easily erected. Ten quintals of straw produced 40 quintals of manure; this is effected either by the addition of the lye, or by the fermentation dilating the material operated on.

"The Jauffret process admits of greater economy as to labor; for the wooden cistern, and the ingredients of which the lye is made, may be carried to the field which is to be manured, and the compost prepared on the spot; and thus the carriage of the vegetable matter from the field to the yard, and back again from the yard to the field, is saved; the escape also of carbonic acid gas, one of the most valuable component parts of manure, which takes place during removal, is thus prevented. The inventor asserts, moreover, that he can vary the degree of fermentation, to suit the defects or qualities of different soils; and as he can raise the heat caused by the fermentation as high as 60 Reaumer (167 deg. Farenheit) his process has the additional advantage of destroying the germ of all noxious herbs, which might foul the land.

"That in considering this process, the committee were struck with the advantage that might arise from establishing manufactories, not only on large farms, but near towns and villages, to which every cultivator might bring his refuse vegetable matter to be converted into manure. The cutting machine might be worked either by horse, water, or steam power.

"The Jauffret process will be advantageous not only to large proprietors, (by whom an expense of 600 francs (£15) will scarcely be felt,) but it will be more important and useful to small farmers, who can cut their weeds by hand, and prepare a quantity as perfect as any made by the machine.* As to the conversion of earth into manure, any one can make it without the help of the machine invented by M. Jauffret, and the manure made from earth by this new process, is not less valuable than the compost. Thus, those who have no cattle to feed may employ all their fodder for manure; others can render available weeds, briers, dogstooth, thistles, &c.; and those who have neither straw, fodder, nor weeds, can convert earth into manure; so that no discovery was ever more capable of easy or general application. The Jauffret process tends to supply agriculturists with new and powerful means of increasing their wealth, especially in the case of poor-land farmers, who usually find it difficult to obtain a sufficiency of manure."

* Mons. Jauffret states, the machine necessary for a small farmer is only a barrel and a pail, and which can be carried with ease from one part of the farm to the other. It is set to work in the open air, wherever materials happen to be; thus the fields that are so distant as to be seldom manured, may by this manure be rendered highly productive. The mixture is made without fire, and every thing concurs to render it economical.

From the British Farmer's Magazine.

MODE AND EFFECT OF EMPLOYING BONE MANURE.

By C. W. Johnson. Esq.

I proceed to notice the effects and modes of applying bones as a fertilizer, either whole, broken, or in the state of powder.

The Doncaster Agricultural Association long since paid considerable attention to the use of bones as a manure, and they have made a very valuable report, to which I have before alluded, of the result of their enquiries, in which they say :—

"The returns received by the association, satisfactorily establish the great value of bones as a manure; our correspondents, with only two exceptions, all concur in stating them to be a highly valuable manure, and on light soils, superior to farm-yard dung, and other manures.

"In copying the language of one of them, in reference to dry sandy soils, we express the opinions repeated in a far greater number.

"I consider bone tillage one of the most useful manures, which has ever been discovered for the farmer's benefit. The lightness of carriage—its suitableness for the drill, and its general fertilizing properties, render it peculialy valuable in those parts where distance from towns renders it impossible to procure manures of a heavier and more bulky description." For, as stated by another farmer, "the carting of six, eight, or ten loads per acre, is no trifling expense. The use of bones diminishes labor at a season of the year when time is of the first importance; for one wagon load, or one hundred and twenty bushels of small drill bone dust, is equal to forty or fifty loads of fold manure. Upon very thin sandy land, its value is not to be estimated; it not only is found to benefit the particular crop to which it is applied, but extends through the whole course of crops."

The report adds, that bones have been found highly beneficial on the limestone soils near Doncaster; on peaty soils, and on light loams; but on heavy soils, and on clay, they produce no benefit.

The mode of applying them is, either sowing by broad-cast, or by the drill, either by themselves, or previously mixed with earth and fermented. Bones which have been thus fermented, are decidedly superior to those which have not done so.

The quantity applied per acre is about twenty-five bushels of bone dust, and forty bushels of large broken bones. The dust is best for immediate profit; the broken half-inch bones for more continued improvement. Mr. Birk, says, "if I were to till for early profit, I would use bones powdered as small as saw-dust. If I wished to keep my land in good heart, I would use principally half-inch bones; and in breaking these I should prefer some remaining considerably larger."

The reason for this is very obvious; the larger the pieces of bone, the more gradually will a given bulk dissolve in the soil.

Such is the result of the application of bones in Yorkshire. In Middlesex, the practice is scarcely different, as will be seen by the answers to some questions I received from a very intelligent correspondent, Mr. John Rayner, of Uxbridge, in November, 1833.

I. On what description of soil is bone-dust employed with the greatest advantage? On light dry soils.

II. The quantity per acre? From twenty to twenty-five bushels.

III. How long has its effects been observed to last? This question requires a more lengthened reply. The good effects of bones as a manure, have been acknowledged by many agriculturists for a number of years: but as farmers, generally speaking, are men who are not fond of trouble, and as there was great difficulty in breaking bones in sufficiently small pieces, to prevent dogs, &c. from running away with them, we can only in a few instance trace out their good effect. There is a farmer in the neighborhood of Watford, who dressed his land with *whole bones*, some twenty years since, (at a period when you could obtain them from London for fetching) and he declares that to this day, to use his own expression, "the land has never forgotten them." Although the first season or so he found but little benefit; this I attribute to the bones being so large, the ground could not so soon act upon them. The *bone dust* is supposed to last but one season; the larger sizes of half-inch and inch, are supposed two or three years, and are always seen to most advantage after the first season.

IV. What is the expense? The dust is 2*s*. 3*d*. per bushel—the half-inch 2*s*.—the inch 1*s*. 9*d*.

V. What is the season, and on what crops is it generally applied? The turnip season. Bone manure shows itself to more advantage on this crop than on any other. It is drilled with a drill made on purpose, with the turnip seed: the period is from May to July. Bone dust is also used with great advantage on grass lands sown broad-cast.

In the valuable and long-continued experiments of Mr. Robert Turner, of Tring, in Hertfordshire, the use of bone manure has been most decidedly successful.

The soil on which these experiments were made, hitherto a common, producing only furze, is sandy, with a substratum of clay, and then chalk. He began the use of bone manure in 1831, *on this land*, and has continued its employment for the last four years on a very bold scale, and with unvaried success. The quantity generally applied was from twenty-four to thirty bushels per acre, of the description of half-inch and dust, and the bones were invariably applied to the turnip crop.

The bones are drilled with the seed at the distance of eighteen inches, and the turnips are always horse-hoed.

The year 1831 was a very good season for this crop generally. The turnips manured with bone dust, like most others in the district, were very luxuriant. About 2,000 bushels of bone manure being this year employed by Mr. Turner.

In 1832, the turnips were in general a very bad plant, the fly committing general devastation. Many cultivators in the neighborhood of Tring, unsuccessfully sowed four or five times.

On the turnip land of Mr. Turner, seventy-four acres were manured with bones. The effect, with the exception of the very last sown four acres, was again most excellent; the crop being very heavy, and that two on land now first cultivated: and there was in no case any necessity to repeat the sowing. The turnips were a much better crop than in 1831.

In 1833, the turnip crops in the neighborhood of Tring, were a very partial crop.

On the farm of Mr. Turner, about fifty acres were manured with bones. The effect, with the exception of some of the last sown turnips, was very satisfactory; the crop very heavy.

These experiments the cultivator will deem of the very first importance; the soil was not manured with any other fertilizer, except bones; and in drilling every now and then, for the drill's breadth, the bones were omitted.

On these breadths of land not boned, the failure of the turnips was general and complete; they vegetated it is true, and came up; but they were wretchedly small, and of no use whatever.

The turnips being fed off, and the sheep folded on the soil, without any distinction being made between boned and unboned land, the comparative experiments upon the succeeding crop were rendered uncertain.

In 1834, Mr. Turner boned about eighty acres of turnips with the best success, and with the exception of some destroyed by the wire worm, had a very excellent crop.

In 1835, on nearly an equal extent of land, notwithstanding the extreme dryness of the season, Mr. Turner had again on his turnips manured with bones, a very excellent plant, and never did this crop promise better than this season, on the lands of Tring.

The caterpillars which devastated the chalk districts of England, did not, however, omit this parish; their ravages were dreadful and complete.

And had not Mr. Turner made a most successful attack upon them by a detachment of six hundred and fifty ducks, procured especially for this purpose, who devoured the black caterpillars with great voracity, his turnip crop would have been utterly destroyed. By their industry, however, twenty-five acres of turnips were cleared of the vermin, and saved from destruction.

At another farm held by the same gentleman, at Ellesborough, by the assistance of the same ducks, who were transported there in carts for that express purpose, saved about eight or nine acres of turnips from the caterpillars; so that there is no doubt of the importance of the services rendered by these birds. He informs me that he found it necessary to give them a quantity of corn while they were thus employed in cleaning the turnips.

The soil of the Ellesborough farm, on which the bones were tried for the first time in 1835, with complete success, is called white land, and was in a very poor state of cultivation. The experiment was entirely successful, and the turnips promised to be very good indeed: those that were saved from the caterpillars, being for the season very excellent.

This soil, called white by the farmars, is probably a mixture of clay and sand; it becomes very dry and loose in dry weather, but is described as "sticky" in wet periods.

Mr. Turner possesses a capital bone mill, worked by four horses, in which he crushes all the bones employed in his farm. He pays for the coarse 2*l*. 15*s*. per ton, and fetches them fifteen miles; a ton of bones producing of half-inch and dust about thirty to thirty-four bushels of bone manure.

The cost of the mill, with the substantial shed which covers the machinery, horse-path, &c. was about £300, and it has been rendered available by Mr. Turner for several other purposes, such as chaff-cutting, thrashing, &c., by which the aggregate expense is materially lessened, and a very considerable annual saving effected.

For the last two years Mr. Turner has drilled with his crushed bones, an equal quantity per acre, of sheep-dung, collected for the express purpose, at an expense of $2\frac{1}{2}d.$ per bushel, paid to the collectors; this he prepares in the winter, by laying the bone dust in alternate layers with the sheep dung, and suffering them to remain fermenting some months until the turnip sowing. By this plan, by the fermentation of the mass, the two manures are thoroughly incorporated, and he considers that thirty-five bushels of the mxture, are fully equal in effect to twenty-five bushels of the bones. So that, allowing 3*s.* 6*d.* per acre for the expense of collecting the sheep dung, there will be a clear saving of 12*s.* 6*d.* per acre in bones, valuing these at 2*s.* per bushel.

The mixed bones and sheep dung is invariably drilled in with the turnip seed.

The practical farmer will hardly need any better testimony of the important value of crushed bones, than these extensive and long continued experiments of Mr. Turner.

They are not open to the common objection to experimental attempts, that they are carried on in far too limited a manner, and for much too short a period, to enable the cultivator to form from them a satisfactory conclusion; for he has annually manured with them scores of acres of turnip land, and that too in seasons which have afforded him, from the adverse price of agricultural produce; but little encouragement to lay out money on any fertilizer of a doubtful value.

I earnestly, therefore, commend these important experiments to the attention of the practical farmer, as being fraught with information of the most interesting nature, especially to those who have to contend with the poor, light, upland soils; lands which are now with difficulty retained in cultivation.

In the year 1831, on a thin chalky soil, in the neighborhood of Amesbury, in Wiltshire, Mr. Devenish employed bone manure of the quality called "fine," drilled at the rate of twenty-four bushels per acre, with the turnip seed, on a portion of a field of about ten acres.

Part of the same field was manured with spit dung, at the rate of about twenty tons per acre, and another portion of the same field remained without any manure.

The Swedish turnips produced on the boned soil, were of four times the value of those grown upon the land manured with spit manure. Those grown on the soil without any manure, were deemed scarcely worth hoeing.

Bone manure presents to the cottager or cultivator of small plots of poor ground, as under the allotment system, a ready and cheap mode of permanently improving his land.

It would be well perhaps, in some instances, if the managers under such an excellent system, were to apply the manure for the holder, and that too, if they even thought it necessary in consequence, to add to the amount of the rent.

As a manure for plantations of trees, I am not aware of any experiments with bones; I should however, strongly recommend their use for ornamental plots; but in a roughly broken state. A considerable quantity of phosphate of lime is contained in all timber trees. There is no manure of a mixed animal and vegetable nature, which remains so long in the soil as bones.

As a manure for flower roots, the turning and clippings of bones, the refuse of the Birmingham cutlers, have long been employed with the best results by my friend Maund of Bromsgrove, the talented author of 'The Botanic Garden.'

Not only does he find their use increase the luxuriance of the plant, and the beauty of its colors, but there is in the application of this powder an elegance and cleanliness which cannot fail of recommending its introduction into the flower garden, and the conservatory.

Such have been some of the successful uses to which bones have been employed. The turnip crop has been the more generally experimented upon from the general difficulty of finding for this invaluable crop a sufficient supply of manure.

And with regard to other crops, the care and labor required for trying with sufficient accuracy a *comparative* agricultural experiment, must account for many discordant statements. Upon grass land, however, it has been employed with very general success; but for the turnip, on poor light soils, it seems of the greatest and most undoubted value. It not only promotes the luxuriance of the plant; but there is a very great probability that the gaseous matters evolved by the crushed and putrifying bone, and the vigor it imparts to the crop, afford the young turnip plants very considerable protection from the ravages of the fly; at least many farmers consider this as one of its valuable properties.

The complete manner in which the roots of the young turnips envelope the pieces of crushed bone with which they are drilled, shows the attractive nature of this manure, and how nourishing it is to the turnip.

I cannot conclude these observations without professing my readiness to assist in any experiments, and answer any questions which may promote a cause now proceeding so successfully. The consumption of bones has already rendered it necessary to import them from foreign countries; and it yet remains to be proved, whether the fossil phosphate of lime will not be nearly as powerful a fertilizer as the crushed or powdered bones usually employed.

General directions.—The crushed bones have been invariably found more immediately beneficial as a fertilizer, when suffered to remain previously for some weeks, mixed with earth in heaps, exposed to the action of the atmosphere. By being thus fermented and dissolved, they are necessarily more speedily serviceable as food to the plants to which they are applied; and this observation more especially relates to the oat, barley, and other spring corn, since these do not remain on the ground for so long a period as other agricultural crops. The proportion is fifty bushels of bones, with five loads of earth or clay; or forty bushels to five loads of common dung.

For wheat and pasture lands, the previous fermentation of the bones is, for this season, not so essential to the production of immediate benefit.

It is impossible to give any general directions for the quantity of bones to be applied per acre, since soil, situation, and climate, must all be taken into the farmer's consideration.

The following facts, however, have been ascertained by numerous experiments, at some of which I have personally assisted.

I. That crushed bones remain in the soil, for a length of time proportionate to the size of the pieces; the dust producing the most immediate effect, the larger pieces continuing to show the longest advantage. On arable land their good effects continue for four years; on pasture land for eight.

II. On turnips, oats, barley, and wheat, the quantity has been from twenty-five to thirty bushels, per acre; on pasture land, from twenty-five to forty bushels of bone *dust*, early in the spring.

III. The best mode of application is by the drill, with the seed corn.

IV. The bones should, when first used, be always applied, for the sake of correct information, in varying quantities per acre; and on no account, should the farmer omit to leave, by comparison, a fair portion of the field, without any manure.

AGRICULTURE, &C. IN FRANCE.

[The following extracts are from a letter received by Dr. Joseph Johnson of this city, from our late fellow-citizen, J. H. Mey, esq., and furnished for publication in the 'Southern Agriculturist.'—*Ed. So. Agr.*]

"*Paris, (France) 15th Sept.* 1837.

My Dear Sir—The "*Academie de Sciences*" amuses me much in their sittings. A subject which may interest you I will state: Dr. Arago asserts, they have dug an Artesian well 1050 feet here without finding water; a thick clay (coat of) prevented them from perforating deeper, but he hopes to overcome the difficulty, and to come to water hot enough to heat apartments, baths, &c.; that heat increases as we descend, and at a certain depth, every thing is in fusion.

Silk worms.—This is a subject of deep concern to our country. Prince and others have propagated and recommended the "morus multicaulis" as the best subject for that purpose—do all you can to destroy this opinion. Noisette, who has studied the "morus" more than others, tells me there is none equal to the common white (morus alba) that the morus multicaulis, after four or five years, dies or vegetates badly. This is experience—profit by it.

In Paris, the culture of the mulberry is progressing rapidly. France consumes and exports 81 millions of silk. 36 to 40 thousand millions are imported from Italy, and they are pretty certain it will succeed here.

M. Beauvais, who has studied the silk worm for ten years, asserts that he is certain of his method being the best, which is to keep them at a higher temperature than 18° (Reaumur), multiply by $2\frac{1}{4}$ and add 32, to make Fahrenheit's=$72\frac{1}{2}$°. His process is reduced to this:—1st, to the employment of a pure and fresh air constantly; 2nd, to a constant dampness of 90° of Desaussure's Hygrometer; 3d, to slight repasts, as many as 48 the 1st, 36 the 2nd, 24 the 3d, and 12 repasts the rest of their education, that is 18 days, making in all 324 repasts; in this way they consume less leaves than at 18 to 20° with 180.* At the last temperature, the worms have less vitality than those kept 4 or 5° higher, they have a different sensibility from the others. B. says he has drawn the source of his information from "Du Halde," and recommends translating all Chinese works on the silkworm.

In England, I observe they have invented a machine to work by steam for making silk, whereby a girl can do as much work as two men formerly, and the space occupied by the machine not as great as before.

A medicinal spring has been discovered near Vicenza, the use of which alone dissolves the stone in the bladder. A man of 70 years old has been cured by drinking it, the stone passing off in small particles. As you keep leeches (I believe) for your information, it is found out that two or three ounces of "animal charcoal," powdered, in water, kept a dozen leaches a year. The powder must be washed two or three times in boiling water previously to being added to the water, in order to disengage it of the sulphuric acid the coal contains. By disgorging them in a little marine salt, and put again into water, in two or three days they are equal to those never used before.

M. Vilmoren has made trial of a species of wheat from New Trinity, which is said to ripen in 70 days, and to give several crops. V—thinks unfavorably of it. I will obtain some seed for our friend Benjamin, if he is in the land of the living.

The *beet root* occupies France very much. I shall myself engage in its culture. A hectare (2,632 toises square of 6 feet) yields from 2100 to 6000 lbs. more than the same lands in the West Indies, and as much as the lands in the East Indies. The cost at present is 50 francs to work it, and it may be made for 30 francs the 100 lbs. In retail, at present, we pay 20 cts. a pound for the best. The government wishes to encourage the West India sugars by laying a duty on their industry at home (taxing it two cents the pound.) I hope this will not succeed, for since the introduction of the cultivation of *beet root*, lands have risen 40, 60, 80 and 100 francs the hectare*—200,-000 men employed in its culture, &c., 18,000 hectares planted, and a capital of 100 millions of francs engaged in it!! This speaks volumes. I recollect in 1815, when Napoleon introduced its culture, a caricature was shown of the young king of Rome, with a beet root in his mouth, crying out, "*Papa dit que c'est du sucre!*" (Papa says 'tis sugar!)

It is worthy of remark, that provisions and property generally on the continent have risen 50 per cent.!! My friend Steinmetz at Mannheim, says, money cannot command more than 3 per cent., and with difficulty 4 per cent. on mortgages.

I recollect seeing at the bank a sample of "*Phormium Tenax*," manufactured. Michaux persists in saying we ought to encourage the planting of this plant. At "Pont St.' Remy" a manufactory is established. Its virtues are, the quality is better than flax, and it may be immersed in water 5 to 7 months without injury; for cables, nets, &c.; of course it is valuable. The "*Laurus Camphora*" will no doubt succeed with us.

"* This idea is no doubt good. Like children—often and little at a time is better for them than heavy meals. The same as in drinking—drink slowly and little at a time, and often, satisfies the thirst, as you know, better than swallowing tumblers-full at a draught!"

* About 2 3-6ths acres, our measure.

M. Bonnet, of "Boulogne sarmer," produced two crops of potatoes in the year; the middle of July he dug up the roots, and planted them six inches deep, trimming the tops to 8 inches. In the day they were covered, and watered in the evening. In three days they became strong and looked fresh; by hilling them afterwards, he had by the middle of October a second crop of 10 to 15 potatoes to each plant, better in quality than the first crop.

The crop of wines generally this year, will not be better than 1835, according to present appearances. The weather has set in rainy, and already speculations are made, fearing injury may be sustained by the present crop. The "Raisin," which gives the Champagne brandy, looks well, and indicates an excellent one, and the quality also excellent.

The nut grass is a *pest* with you. May it not contain a tanning principle? It is astringent; draw the attention of some able chemist to the subject.

From the British Farmers' Magazine.

HOLKHAM ANNUAL CATTLE SALE.

Exhibitions of fat stock, be they of bullocks, sheep or swine, merely considered as so many vehicles for the manufacture of suet, tallow, or bacon, have never been greatly to our taste; and for choice, we would at any time prefer a vein of one inch of fat upon the ribs, to more. We shall doubtless be regarded as mere Goths for holding these our heretical opinions; but "such is our fate," and we must even put up with the obloquy attached to our unpopular notions of meat, meet for home consumption, rather than bolt the *bons bouches* of our worthy friends, the patrons of the new Leicester pigs, that have made beasts of themselves, or any other *precieuses morceaux* of the oleaginous, porpoise-like breeds of our acquaintance. So far do we carry this our feeling, that, fond as we are of music, we never could wholly divest ourselves of prejudice even against the first and finest of our modern vocalists, solely because she is *Grisi;* nor would any consideration tempt us to select a *rib* of the unctuous name of *Fatima.*

However, joking apart, we are not insensible to the value of specimens of early maturity in *quadrupeds*, mind; and we hold that a disposition to fatten, by cattle or sheep when young, is, and ought to be, one of the first qualifications in the eye of a farmer; nor are we by any means inconsistent in asserting, that without attention to this particular, the toil and trouble of the breeder are thrown away. It is the abuse, not the judicious use of this quality, at which we have been pointing; for though there are some animals which it is next to impossible to fatten; yet there are others, which, by dint of stuffing and cramming, may, even in the hands of an unskilful feeder, be made to *appear* better than they really are: for fat, like charity, covereth a multitude of faults. I would instance the common breed of pigs in this county. They will get as fat as most others of their species; but it is *all* fat. The bacon is very fair, to outward appearance, but what is the substratum? It is deficient in *flesh;* without a due proportion of which, the main ingredient of a perfect animal is wanting. A layer of bacon, more or less thick, is laid on to bare bones, or little better; whereas a Berkshire pig, to all appearance not half so well made up, is infinitely superior in point of quality, because it combines a full and fair quantum of meat, on which to apply any reasonable share of fat. There is a good and solid foundation to begin upon. A friend of ours once took the pains to illustrate, by experiment, the deceptive nature of this *spurious* coating of fat, for so it may not improperly be termed. We admit that this illustration of his is somewhat overstrained; still, it furnishes an useful hint as to the propriety of due attention to lean as well as fat; and, at all events, proves the truth of the old adage, "all is not gold that glitters." He fatted a pig on oil-cake alone. The animal, to all appearance, did well—in my friend's own words, "got fat in no time;" and very fat, too—but what sort of fat was it? You shall hear. On being exposed to the fire, it melted away, leaving nothing but sheer grease! And yet, when living, he was thought "a very pretty pig" by all the neighbors!

The North Devons sold on Wednesday, the 13th, at Holkham, (the particulars of which we shall now proceed briefly to detail,) were beautiful specimens of quality of meat, and symmetry of form; and exhibit a striking proof of what may be done with good blood in skilful and intelligent hands. Four bullocks of this very handsome breed, three years' old off, were justly extolled as perfect pictures, and fetched £36 each. Several others averaged £34 each.

The two-shear Down wethers (splendid specimens of that truly valuable breed of sheep) fetched as high as £4 8s.; and the shearlings of the same breed £3. 6s. Twenty pigs attracted great attention, and sold for £5 6s. 8*d.* each. On the whole, it must have been highly satisfactory to the noble and venerable Earl of Leicester,* to see his labors so well appreciated by the many excel-

---

* It may not be superfluous information to most American readers, to say that this is the title, or *nick-name* under which the illustrious name of Coke is now disguised and hidden. The Norfolk farmer. Thomas William Coke—whose great agricultural improvements, and labors, were as valuable to his country as profitable to himself, and whose well-earned fame had extended as far as agriculture was prized, and whose name belonged to the whole world—refused, when it was offered at a former time, to permit his name to be exchanged for an ea,l's title. But recently, whether from uxoriousness, or the commencing imbecility of old age, he has yielded his consent, and henceforth will be comparatively scarcely recognized as the Earl of Leicester. As he has consented to be thus degraded, and to forfeit the proud name for which he had acquired more true honor and respect, than can be justly claimed for any other now borne by living man, it would have been better than an unmeaning, though ancient title, if he had assumed one having reference to the labors of his long and useful life, and the grounds of his great public services and fame. Thus, it would have been somewhat less degrading to Mr. Coke, if, instead of the earldom of Leicester, he had received the title of "Earl of Turnips," or "Duke (Dux) of South-Down Sheep," or even the lesser dignity of "Baron of Red Clover."—ED. FAR. REG.

lent judges, some from a considerable distance, who attended the sale, as purchasers: nor could it be otherwise than gratifying in the highest degree to Mr. Bulling, the steward, that *his* exertions on the occasion were crowned with so successful a result. It was generally remarked, that seldom did the noble Earl appear in better health, or more bouyant spirits, than during the sale. He was attended by his amiable Countess, Lord Waterpark, and a numerous party of distinguished guests, who seemed thoroughly to enter into, and enjoy the novelty and bustle of the scene." * * *

From the Annual Register, of 1763

THE VELOCITY OF HORSES IN THE RACE PHILOSOPHICALLY CONSIDERED, BY MONSIEUR CONDAMINE. FROM HIS TOUR IN ITALY, IN THE YEARS 1755 AND 1756.

The spectacle which at present forms the amusement of the people of Rome, retains nothing of the barbarity of the ancient combats of gladiators. Some of the princes and Roman noblemen amuse themselves by keeping horses purely for the course; not as in England, backed by a rider; but alone, at full liberty, and entirely delivered up to their natural ardor, and that kind of emulation which the concourse of people assembled seem to inspire. Eight or ten horses, commonly barbs, of a small size, and mean figure, retained on the same line by a rope extended, about the height of their breast, set off at the instant when they let this rope fall. In the races at carnival time, which are the most solemn, the course is usually in the long street at Rome, to which this exercise has given the name of El Corso, or race street. They take care, at such times, to gravel it over. The length is 865 toises. I observed twice, by means of a watch for seconds, and the help of a signal, that this distance was run over in 141 seconds, which makes near 37 feet a second. A little reflection will make this speed appear much more considerable than at first we may imagine it to be.

It is evident that we cannot suppose more than two leaps or progressions on gallop, to one second, seeing that each of these leaps requires at least three very distinct points of time, viz: that in which the horse lifts himself from the ground; that in which we see him cleaving the air, and that in which he descends again; and that these two bounds, thus supposed to be made in every second, require six definate movements, a period scarce perceptible in so short a space of time. These horses, which are but of an inconsiderable size, and whose swiftness, every second, is equal to 37 feet, pass then, at each bound, over a space of more than 18 feet, which is very near equal to four times the length of their body, taken from the breast to the tail. It is true, indeed, that this length is more than doubled by the extension which their outstretched gallop gives their limbs before and behind. All this considered, how can the fleetness of the English horses be by a great deal, greater, as it is known to be in reality? But there are certain cases wherein the truth surpasses all the bounds of probability, and of this kind is that at present under consideration.

The late Monsieur Dufay writ in 1737, from Newmarket, that the course there, of four English miles, had been completed in less than 8 minutes, by 4 or 5 seconds. These miles are 826 of our toises, which makes more than 41⅔ feet in a second, or near 5 feet more than the barbs at Rome, and we must also remark here, that the latter run at full liberty, whereas the English horses are burthened with the weight of a rider. This fleetness, however, of 41⅔ feet, is still but an ordinary degree, of swiftness there, inasmuch as of ten horses which ran together, the very hindmost of them was no more than 12 to 15 paces from the end of the course. Besides, it is asserted that the same course had been frequently run over in 6 minutes and 6 seconds. I have this as a fact from a gentleman who has been concerned in the races at Newmarket.* And this swiftness, which would amount to more than 54 feet in a second, is to that of the barbs nearly as 3 to 2. We must also observe, that instead of one English mile, or a little more, to which the course of Rome is limited, that of Newmarket is 4 miles—a space too long for the swiftness of any horse to preserve itself through, on a sensible equality. It is evident that this swiftness cannot extend through the whole course, and consequently at the moment of the race, when it is at its maximum, the impulsion must be upwards of 54 feet in a second. We are likewise assured that a famous horse called Starling, has sometimes performed the first mile in a minute, which would make 82½ feet in a second—a degree of swiftness, which, if there be no exaggeration in the statement, is almost inconceivable. But this is a point on which I expect some further elucidations.

[The following are the elucidations I have received, since the reading of this memoir, from Dr. Maty, keeper of the library of the British Museum:—]

There are, says Dr. Maty, two courses at Newmarket—the long, and the round. The first is exactly 4 miles and 380 yards; the second is 4 miles, less 400 yards. Childers, the swiftest horse ever remembered, has run the first course in 7 minutes and 30 seconds; and the second in 6 minutes and 40 seconds, which amounts to 46 feet 9 inches French, in the second. Whereas, all other horses except the foregoing, take at least 7 minutes and 50 seconds in completing the first and longest course, and 7 minutes only in the shortest—which is 44 feet 5 or 6 inches the second. These are facts, adds Dr. Maty, which I believe to be true. I must also add, that it is commonly supposed these coursers cover, at every bound, a space of ground 24 English feet in length.

This is a little inside of my conjecture of two bounds in the second. Every bound in this case would be about 18 royal feet and a half for the fleetest barb in Rome, and 22 or 23 feet and a half for English running horses. So that the swiftest of the latter to that of the barbs, is very nearly as 4 to 3.

From the New York Farmer.

EXTRAORDINARY PRODUCTIONS ON A SMALL FARM.

[We are indebted to a distinguished member of the legal profession for the following communica-

*Mr. Faafe, then at Paris, since dead.

tion written by a friend of his, who, in addition to an extensive and profitable business carried on in this city, finds time to cultivate a miniature farm —and it may also be considered *a model* farm—in New Jersey.

This statement, which may be relied on, of the products of 3552 *square feet*, which is a fraction less than *one and a half* city lots, or a *farm* 100 feet long by 35 feet 6¼ inches broad, shows what *may* be accomplished by those who believe *in*, and have the industry to practice *upon*, "*book* farming." It teaches a lesson worthy of being studied and practised upon by thousands in, and in the vicinity of, this city and elsewhere. We shall endeavor to obtain further details in relation to these extraordinary productions, for the purpose, and with the hope, of inducing others to profit by becoming "farmers" on a similar scale, or larger if they choose. If they will manage as well in proportion as J. L. L., the writer of this communication has, and furnish us for publication their annual report, we will place the result on record without fee or reward.—Ed. N. Y. Far.]

Hoboken, Dec. 11th, 1837.

To J. Anthon, Esq.

Sir—Agreeable to promise, I enclose you the result of my last season's cultivation, ending at date; also a statement of the cost and keep of domestic animals, &c.

I uniformly look well to the result of all my undertakings; but the gain from one cow exceeds my most sanguine expectations; and it is a confirmation that whole families of the peasantry in Europe are supported chiefly on *one* cow. I will say nothing of the luxury of *pure* fresh milk and butter, as I know you have them in abundandance; but hereafter, I shall never be without one of those most useful animals. I shall take another opportunity of showing you that pure milk is not "feverish;" but that from neglect and starvation the poor cow may become fevered, and thus affect her milk.

You will perceive that the *vulgar* pig is the most profitable; this accounts for the poor man's habitation being surrounded with them. However, my pigs were penned and fed on pumpkins and corn.

The fowls, owing to the high price of corn and grain for two seasons past, are not so profitable; but they are of the Sicillian breed, as big as turkeys. Not having bought vegetables (except potatoes) for two seasons past, I do not know what price to attach to my produce. Will you put the market price to each, and strike a balance? This will enable us to estimate the value of a well cultivated farm of 20 to 50 acres.

My outlay for seeds and plants is just \$3 50. The labor is my morning and evening's exercise, with the assitance of my cow-boy in weeding and digging.

It would be an idle boast to rise with the sun, to plant cabbages and raise turnips, but if I can produce choice wholesome fruit and vegetables *out* of season, in our climate, then I may flatter myself that I have made my "blade of grass grow where none grew before."

I fattened pigs to obtain three results.

1st, Furnish to my household good wholesome food.

2nd, Save money in my expenditure.

3rd, Obtain manure, which is not to be got where I am, unless at a heavy cost.

I will here state that my vines are quite young. I did not think it prudent to allow all the fruit formed to remain, another season: I estimate my crop of grapes at three fold. As you have seen, during the past season, samples of the principal of my fruit and vegetables, I will add a few more that you have not seen. I should also send you some choice cauliflowers; but I understand that you had an abundance.

In regard to my butter-making experiment, thus far I am successful; but I will lay no claims to the "medal," until I get through the three next months; they will be the most trying.

In making comparisons with the result from my *miniature farm*, you must make due allowance, that I am a farmer of only two seasons.

The sample of butter I now send you, I think is as fine as any made during the summer.

I also send you a taste of sausages made on my *farm* from my pig: if you eat sausages, you must compare, by purchasing some in the market.

I shall try the experiment of making Westphalia hams from my pork.

Also, bacon that shall look like a cherry when you cook it.

Yours respecfully,

J. L. L.

Statement.

3552 square feet of ground under cultivation produced in one season the following in four crops:

First Crop.

Lettuce, cart loads,	2
Radishes, bushels,	1
Pepper-grass, chives, etc.	

Second Crop.

Green peas, bushels	3
French beans, do.	2
Early cabbages, heads	210
Cucumbers, bushels,	1
Cherries, do.	2¼
Pot-herbs of every kind.	

Third Crop.

Sweet corn, bushels,	2
Yellow and white flint, bushels,	1
Lima and Cranberry beans, do.	3½
Squashes,	70
Okra, bushel,	½
Onions, do.	1
Leeks, do.	½
Tomato, do.	3
Pumpkins, average 17 lbs. each,	53
Beets, bushels,	2
Carrots,	½
Nasturtium (for pickles) gallon,	1
Pears, (bad season,) bushels,	1½
Grapes, golden Chasselas, average ½ lb. each bunch, bunches,	33
Grapes, Isabella, average half pound each bunch,	80
Gooseberries, currants, etc.	

Fourth Crop. *

Cauliflowers, heads,	- - - - -	50
Celery, do.	- - - - - -	75
Scotch kale, do.	- - - - - -	50

Ruta-baga, 3500 plants expressly for the leaves.

Statement of the cost and keep of a cow, with an account of her produce:

Dr.

April 1836,	Cash paid for cow,	$20,00
to	Do. for hay,	42,00
Dec. 1837,	Do. corn-meal,	20,00
	Do. pasture,	12,00
		$94,00

Cr.

April 1836, to Dec. 1837.	By 225, lbs. butter 2s. per pound, - - - -	$56,25
	Calf sold for - -	12,00
	Milk for house estimated at two quarts per day,	45,50
	Cash received for milk sold chiefly butter milk,	147,25
		$261,00
	Deduct,	94,00
	Gain on cow,	$167,00

Statement of the cost and keep of two pigs:

Dr.

Oct. 1837.	Cash paid for two pigs,	$10,00
	Do. for corn meal,	2,00
		$12,00

Cr.

Dec. 1837.	By 160 lbs. pork, 8 cents per pound	$12,00
	By seven pigs fit for table in three weeks	14,00
	By one sow, value	12,00
		$38,80
	Deduct	12,00
	Gain on two pigs,	$26,80

Statement of the cost, keep and produce of 3 pair chickens.

Dr.

Sept. 1835, to	Cash paid for three pair chickens,	$ 2,50
Dec. 1837.	Do. for oats, corn etc.	57,25
		$58,75
Sept. 1835, to	By 2500 eggs 12d. per dozen	$26,62
Dec. 1837.	By 143 fowls,	71,50
	Carried forward	98,12

* The whole of the fourth crop is at this time growing in the open air, except the cauliflowers, which have been taken up, from time to time.

Brought over	98,12
On hand 16 do.	8,00
	$106,12
Deduct	59,72
Gain on chickens,	$46,37

From Johnson on Liquid Manure.

ON THE USE AND VALUE OF LIQUID MANURE.

The absolutely fluid portion of the London sewers consists, generally speaking, of a mixture of urine, soap-suds, street, and other washings, blood from the slaughter houses, &c. &c., an immense mass of liquid which is naturally of the most fertilizing description. Thus it has been found by those who are most deeply conversant with the admirable system of irrigation, or watering meadows, that the water taken from a river *below* even a small town, is infinitely more fertilizing, from its waters being mixed with the town drainage, than when taken from the river *above* the town, and consequently unmixed with the sewer waters. These matters can almost always be made available near large cities, and there are one or two cases with which I am acquainted, as in the fields near Musselburgh, which are traversed by the Edinburgh town drain waters, in which the use of the mass is productive of a growth of grass of the most luxuriant description, ensuring to the farmer four or five crops in each year. And it must be remembered in the cases which I have quoted from the practical observations of the talented irrigators of the south of England, that the drainage, which they have found so useful, is not employed by them as it issues from the town sewers, but is, in fact, mixed and diluted with all the waters of the river. Liquid manure has ever been gladly and zealously employed by the most able cultivators of the earth from very early periods, and is daily coming more and more into use, even with the most sluggish and indolent farmers. The knowledge of its value too is not confined to one country, nor has it been one of the many valuable modern products of vegetable chemistry. Thus we learn from Sir George Staunton, ('Embassy to China,') that the Chinese farmers ever prefer night soil mixed with water; and irrigation, which is, as usually practised, the most diluted method of applying liquid manure, was known to the Roman farmers in Virgil's days. *Georgics*, l. iv. 106—9.

It is hardly necessary to show that the urine, the blood, the soap-suds, and other fluids of the London drains, are well known fertilizers, since every farmer is aware of the fact. He gladly saves all descriptions of urine for his dunghill—carefully collects and carries, even for miles, the semi-fluid refuse of the slaughter-houses, and readily gives a considerable price for even the soap-maker's waste, since he is fully aware of the value of the small quantity of alkaline matters yet remaining even in that; and while I am writing this sentence, a paragraph has been pointed out to me in an excellently conducted paper, the 'Sussex Agricultural Express,' which details the admirable fertilizing results of using, as a watering for vegetables, a very weak solution of soda (one pound in fourteen gallons) and states, as an instance, that the vegetable marrow-plant, when growing in common mould, has been found to surpass other plants growing in a bed of dung. The London drainage waters always contain the soda in its fluid portion, the soda of some thousand tons of soap, consumed annually in London, all finding their way into the sewers.

Nature is here again our instructor. The fertile fields of Syria, and some of the most profusely luxuriant lands of the orientalists, abound in carbonate of soda. This alkali not only enters into the composition of many vegetables, but it promotes the growth of all, by preserving the moisture of the soil, and by accelerating the decomposition of the numerous organic substances found in all cultivated lands.

To the immense quantity of urine which is mixed with the drainage waters of large cities, one source of their fertilizing powers must be mainly attributed, a fact well known equally to the farmer and to the chemist. "All urine," said the late talented Davy, "contains the essential elements of vegetables in a state of solution. During the putrefaction of urine the greatest part of the soluble animal matter that it contains is destroyed; it should consequently *be used as fresh as possible;* but if not mixed with solid matter, it should be diluted with water; as when pure it contains too large a quatity of animal matter to form a proper fluid nourishment, for absorption by the roots of plants. *

Urine has been subjected to the most careful analysis by M. Berzelius, the great Swedish chemist, and its constitutents are determined by him to be as follows.

Water - - - - - - -	933 00
Nephrin (peculiar to animal matter,)	30 10
Sulphate of potash, - - -	3 71
Sulphate of soda, - - -	3 16
Muriate of soda (common salt,) -	4 45
Phosphate of ammonia, - -	1 65
Muriate of ammonia, - - -	1 50
Lactic acid, - - - - -	} 17 14
Lactate of ammonia, - - - -	
Animal matter, mixed with nephrin,	
Earthy phosphates, (earth of bones,) and fluate of lime, - - -	1 00
Uric acid, - - - - - -	1 00
Mucus, - - - - - -	0 32
Silica *(flint,)* - - - -	0 03
	10 00†

Well might Davy exclaim after such an analysis, that "all urine contains the essential ingredients of vegetables;" its magic fertilizing effects when spread upon the earth, need no longer puzzle the agriculturist, since there is hardly a single ingredient detected by the analysis of M. Berzelius, which is not either direct food for vegetation, or furnishes, by its decomposition, a supply in another form. It contains all the ammoniacal salts of the dunghill, the phosphate of lime of bones, and abundance of easily decomposable animal matters.

On the use of the liquid portion of the Edinburgh town drainage, a very able report has been made to the Thames Improvement Company, by Mr. Thomas Oliver, an excellent Scotch farmer, in which he says, "from the elevated position of Edinburgh, there is a considerable extent of ground which can be overflowed by the water from the city drains, in its progress to the sea, and of late years it has become an object of attention to the proprietors and occupiers of ground, so situated as to admit of its application; there are, I should think, not less than three hundred imperial acres to which it is regularly applied, and with great advantage."

"Such ground is annually kept in grass and yields from *three* to *six* cuttings in the season, which is let to dairy-men and others, at rents varying, according to circumstances, from twelve to twenty-four pounds per acre. You will perceive from this statement, that the chief benefit derived from the drainage of Edinburgh, arises from the fluid part; and if we reckon the increased yearly value of the land, above-mentioned, at ten pounds per acre (which I think is under the mark) it yields a clear revenue of three thousand pounds per annum to the proprietors of those grounds through which the drains pass." *

The history of the adoption of this system of town drainage irrigation at Edinburgh is very interesting, and will, therefore, abridge and insert the description given of it by Mr. Stephens. † "Edinburgh," says this intelligent land drainer, "has many advantages over the most of her sister cities; the large supply of excellent spring water is one of the greatest blessings to her numerous inhabitants, both in respect to household purposes and keeping her streets clean, as well as irrigating the extensive meadows situated below the town, where the art of man, with the common sewer-water, has made even sand hillocks produce riches far superior to any thing of the kind in the kingdom, or in any other country.

"By this sewer-water about two hundred acres of grass land, (1834) for the most part laid into catchwork meadow, are irrigated; whereof one hundred and thirty belong to W. H. Miller, Esq., of Craigintinny, and the remainder to the Earls of Haddington and Moray, and other proprietors. The meadows belonging to these noblemen, and part of the Craigintinny meadows, or what are called the old meadows, contain about fifty acres, and have been irrigated for nearly a century. They are by far the most valuable, on account of the long and continual accumulation of the rich sediment left by the water; indeed the water is so very rich, that the tenants of the meadows lying nearest the town have found it advisable to carry the common sewer water through *deep ponds*, into which the water deposites part of the superfluous manure before it runs over the ground. Although the formation of these meadows is irregular, and the management very imperfect, the effects of the water are astonishing; they produce crops o grass not to be equalled, being cut from four to six times a year, and the grass given green to milch cows.

"The grass is let every year by public sale, in small patches of a quarter of an acre and upwards, and generally brings yearly from twenty-four to thirty pounds per acre. In 1826 part of

* Agricultural Chemistry, p. 295.

‡ Annals of Philosophy, vol. ii. p. 422.

* Paper of Dr. Granville. Rep. of Committee, p. 75.

†Practical Irrigator—copied at length in the Farmers' Register, begining p. 347, vol. iii.

the Earl of Moray's meadow fetched fifty-seven pounds per acre.

"About forty acres of the Craigintinny lands were formed into catch-work water-meadow before the year 1800, which comprises, what is call Filfieside Bank old meadows, and is generally let at a rent of from twenty to thirty pounds per acre. In the spring of 1821, thirty acres of waste land called the Freegate Whins, and ten acres of poor sandy soil, were levelled and formed into irrigated meadow, at an expense of one thousand pounds. They now bring from fifteen to twenty pounds an acre per annum, and may be much improved.

"This," continues Mr. Stephens, "is one of the most beneficial agricultural improvements ever undertaken; for the whole of the Freegate Whins is composed of nothing but sand deposited from time to time by the action of the waves of the sea. Never was one thousand pounds more happily spent in agriculture; it not only required a common sewer to bring about this great change; but a resolution in the proprietor to launch out his capital on an experiment of a soil of such a nature. One hundred and ten acres of Mr. Miller's meadows in 1827 gave a clear profit of two thousand and ten pounds; the yearly expense of keeping these meadows in repair is from ten to fifteen shillings per acre, which is more than double the expense of keeping water meadows in repair in general; for the watering of them is not only through the winter season, but the water is put on them for one or two days together, immediately after every cutting of the grass, throughout the whole of the season."

It must not be forgotten in the consideration of these very important facts, the northern situation of the good city of Edinburgh; for it is in the same latitude as St. Petersburgh, and therefore the warmth of the meadows around it, and the consequent rapid growth of the grass, as compared with those of the valley of the Thames, must be under the same circumstance greatly inferior.

The forcing quality of liquid manure, as shown by the constant result of irrigating with common water, and as still more strrikingly confirmed by the use of the Edinburgh town drainage waters, is entirely confirmed by the practice of Mr. Knight in the employment of liquid manure for fruit trees, which I cannot give better than in his own words.

'I have shown in a former communication," says this able vegetable physiologist, "that a seedling plum-stock, growing in a small pot, attained the height of nine feet seven inches in a single season; which is, I believe, a much greater height than any seedling tree of that species was ever seen to attain in the open soil. But the quantity of the earth, which a small pot contains, soon becomes exhausted relatively to one kind of plant, though it may be still fertile relatively to others; and the size of the pot cannot be changed sufficiently often to remedy this loss of fertility; and if it were ever so frequently changed, the mass of mould, which each successive emission of roots would enclose, must remain the same. Manure, therefore, can probably be most beneficially given in a purely liquid state; and the quantity which trees growing in pots have thus taken, under my care, without any injury, and with the greatest good effect, has much exceded every expectation I had formed.

"I have for some years appropriated a forcing-house, at Downton to the purposes of experiment solely upon fruit trees; which as I have frequent occasion to change the subjects on which I have to operate, are confined in pots. These at first were supplied with water, in which about one-tenth by measure of the dung of pigeons, or domestic poultry, had been infused; and the quantity of these substances (generally the latter) was increased from one-tenth to one-fourth. The water, after standing forty-eight hours, acquired a color considerably deeper than that of porter, and in this state it was drawn off clear, and employed to feed trees of the vine, the mulberry, the peach, and other plants; a second quantity of water was then applied, and afterwards used in the same manner; when the manure was changed, and the same process repeated.

"The vine and mulberry tree being very gross feeders, were not likely to be soon injured by this treatment; but I expected the peach tree, which is often greatly injured by an excess of manure in a solid state, to give early indications of being over fed. Contrary, however, to my expectations, the peach tree maintained at the end of two years the most healthy and luxuriant appearance imaginable, and produced fruit in the last season in greater perfection than I had ever previously been able to obtain from it. Some seedling plants had then acquired, at eighteen months old, (though the whole of their roots had been confined to half a square foot of mould,) more than eleven feet in height, with numerous branches, and have afforded a most abundant and vigorous blossom in the present spring, which has set remarkably well; and those trees which had been most abundantly supplied with manure, have displayed the greatest degree of health and luxuriance. A single orange tree was subjected to the same mode of treatment, and grew with equal comparative vigor, and appeared to be as much benefited by abundant food, as even the vine and the mulberry tree.'

As it is, therefore, evident from the concurring practice of not only the talented agriculturists of our own country, but of those of all parts of the world, from China to Egypt, from the low lands of northern Italy to those of Holland, that the value of any liquid manure is as great as that of the more solid; is it not more desirable, even in a national point of view, that every facility should be given to its collection and disposal? And if the drainage, from a small country-town is distinctly found to render even the passing waters of a river more fertilizing to the meadows on its banks, how strongly does this fact show the immense values of the fluid matters hourly wasted in the huge drainage of London, none of which has hitherto been employed for the purposes of irrigation? and should not some plan be speedily devised by which this rich liquid portion may be made available, if only on the great marshes of Essex and Kent? Let it not be concluded that the earthy, animal, and vegetable matters brought down by flood waters of large rivers, are of a small aggregate amount, for such is not the case; all the extensive marshy country at the mouth of the Mississippi, has been formed by the deposites of that mighty river, and the same remark applies to the Ganges, and the Delta of Egypt. It has been calculated that the Mississippi carries into the sea 8.000,000 cubic feet of solid matter every hour, and it has been clearly established that at least 700.000 tons of animal and vegetable manure finds its way yearly into the Thames, through the sewers of London.

From the London Mechanics' Magazine.

CAOUTCHOUC ROOFS.

Sir—As yours is a repository for many crude (as well as perfected) inventions, which may afterwards be the groundwork for others of the greatest value and importance to the public, I beg to request you will lay before your readers the following suggestions for a new application of caoutchouc or India-rubber.

I have thought, that if the tops of house could be flat, and have reservoirs of water upon them, that water might be made available as a supply for domestic purposes to every room in the house, and also that screw-hose might be fixed thereto for the purposes of extinguishing any fire in the room where it originates on its first discovery. Hitherto, lead has appeared the most suitable material for roofs; but weight, price, and contraction by the heat of the sun, have been great objections. May not India-rubber be advantageously substituted? If prepared in large sheets, one-eighth or three-sixteenths of an inch in thickness, they might be laid on, and afterwards the joinings made perfectly secure by the solution of caoutchouc; and in case of damage from any cause, it might easily be repaired by the same means. Some of your more scientific readers can give the necessary strength of wall and timber for bearing the various depths of water which might be required. I apprehend that in large buildings, such as the new houses of parliament, it would not only be advantageous as a preventive of fire, but also more economical. Yours,

A Constant Reader.

NOVEL AND GRAND SCHEMES. BRIDGE OR TUNNEL FROM DOVER TO CALAIS.

Mr. Coppett, an English engineer, is now on his road to Paris to lay before the French government a project for constructing a passage to cross dryshod from Calais to Dover. He at Havre explained his plan to the public. Mr. Coppett asks of France only one milliard, and as much from England. With this trifling sum, he will make cones like those employed at Cherbourg, between fifty and sixty years ago. If the government does not approve of this system, he has in his pocket three or four others. For instance, he will make a tunnel under the sea from Dover to Calais introducing from one end to the other cast-iron pipes eighteen feet in diameter. This last mode of communication, according to Mr. Coppett, would cost only one milliard, to be paid in equal portions by both countries.—*English Paper.*

From the Quarterly Journal of Agriculture.

EMBANKMENTS FROM THE SEA.

There seems to be no operation connected with agriculture which promises more immediate and important results than the reclaiming of submerged lands in the estuaries of our large rivers. Till within these thirty years, the sole object contemplated in embanking submerged grounds, seems to have been the exclusion of water from the surface of soil which required only to be protected from its occasional invasions, and kept dry merely to make it eminently fit for most productive cultivation. Within the last twenty years, a system has been entered on, and is now, in the Forth and Tay in particular, being carried out to the most astonishing extent, not only of bringing into a cultivable state lands already, but for the periodical submergence, fit for cultivation, but of causing rivers to precipitate their mud in convenient localities, and so of creating fields where nothing before existed but a gravelly river bed, covered by from eight to twelve feet of water every tide, of the most unprecedented and unlooked-for productiveness.

In the Forth, 350 acres of this sort of land have been, in the last twelve years, reclaimed by Lady Keith, at a cost of about £21,000, and affording an annual return of about £1400, or nearly seven per cent. In the Tay, seventy acres have been recovered, opposite to the shores of Pitfour, 150 on those of Errol, and twenty around Mugdrum Island, making in all 240 acres, at about an outlay of £7200, yielding an annual rent of about £1680, or upwards of twenty-three per cent! On the Errol estate alone, 400 acres are just about to be embanked, in addition to the above 150, all of which may probably be in cultivation before 1847. Off the shores of Seaside, a wall just now being built, 800 yards in length, will effect the recovery of not less than 150 acres; and on Murie property, 50 acres might be taken in by seed-time 1838. The operations of the embanker, which began off Pitfour in 1826, will thus probably have brought into cultivation before 1846, on a shore of not more than seven miles in length, no less than 810 acres of land, renting at from £6 to £7 per acre, or of a gross annual value of £5670, and a gross total value, at twenty-five years' purchase, of £141,750. This is a clear creation of £117,450 of new agricultural capital, taking the reclaiming cost at £30 an acre. The junction of Mugdrum Island to the north shore, would probably afford 1000 acres at a single operation, while thrice that surface might be obtained betwixt Errol and Invergowrie.

The capabilities of the Forth, over and above what has already been effected above and below Kincardine, are not much, if at all, behind those of the Tay, though no sufficient inquiry has been made to permit details to be gone into.

The basin of Montrose affords a surface of nearly 3000 acres, all capable of embankment, and which, by being relieved of the salt water of the ocean, with which every tide at present overflows them, and keeps them submerged for twelve hours out of every twenty-four, and irrigated by the fertilizing current of the Esk, which, for at least forty days every season, bears along with it not less than $\frac{1}{300}$th part of its weight of the richest mud, might speedily be made not less productive than those of the Forth or Tay.

It is probable that between North Berwick and Montrose are to be found the most favorable localities for embanking on the east coast of Scotland, if not indeed the only ones which could be made available with a sure prospect of profit. It would be at the same time well that the debouchures of all our great rivers were examined, lest at the mouths of the Spey, the Dee, the Don, the Esk, and the Tweed, might lurk localities equally accessible to the embanker, and equally unlooked-for, or more, than in the Tay or Forth thirty years since.

If the harbors on both sides of the Forth be examined, as low down as Dunbar on the one side, and Crail on the other; and those on the Tay down to Broughty Ferry; those on the Esk to Montrose and Ferryden, large quantities of silt will be found accumulating in each of them, quite as impalpable and fine, and probably, if freed of salt, as fertile as those deposited and taken in higher up the rivers. It is probable, then, that lands might be embanked much farther out in these estuaries than seems at present to be suspected, by much the greater part of the argillaceous flocculi which the river bears along with it being actually carried out to sea.

The various embankments hitherto completed have been constructed by those manifestly little acquainted with hydraulic engineering, with little concert amongst the proprietors, and without almost any recognition of general principles, or systematic plan of procedure. Many anomalies are consequently apparent in the now finished works, and many cases of useless expense and annoying inconvenience have arisen, which it would have been most desirable and not difficult to have avoided.

On these and on many other grounds, which must be apparent, but to enter into a detail of which would be much too tedious for the present memoranda, it seems most important that something should be done in the way of a historical account of all the embanking operations of any importance in Scotland, whether for the purpose of merely defending lands previously existing, but liable to periodical inundations, from tides or river freshes, or for the purpose of obtaining and inclosing accumulations of silt, which, but for the skill and industry of man, would have been wholly swept away.

From the Quarterly Journal of Agriculture.

ON THE PROPAGATION OF THE APPLE-TREE.

In the number of this Journal for September 1837, I observe the following statement, among the Miscellaneous Notices:—

"*Propagation of apple-trees.*—A new plan for increasing plantations of apple-trees has lately been carried into extensive practice by the horticulturists of Bohemia. Neither seed nor grafting is required. The process is to take shoots from the choicest sorts, insert them into potatoes, and plunge both into the ground, leaving but an inch or two of the shoot above the surface. The potato nourishes the shoot, while it pushes out roots, and the shoot gradually grows up and becomes a beautiful tree bearing the best fruit, without requiring to be grafted. Whatever may be the success of the undertaking, its novelty at least is an inducement to give it a fair trial."

I beg leave to remark that six or eight years ago a similar statement was published. It was not then represented as a general practice, but merely as the successful operation of an individual in Bohemia. In consequence of the publication, I immediately made the experiment. I took cuttings of various apple-trees, and inserted each cutting in a potato, and planted the potato and cutting, leaving only an inch or two of the shoot above the surface. The consequence was that *the potatoes did grow*, but the *apple-tree cuttings did not grow.* It then occurred to my gardener, James Smith, who had long been employed as a nurseryman, that we should have sliced off the eyes of the potatoes. Next year this was done and the experiments repeated, but the potatoes still grew, but not the apple cuttings. The experiments were tried, not only in the country, but also in the back ground of a house in the New Town of Edinburgh, but in no instance with success.

It has since occurred to me that to complete the experiment we ought to have *boiled* the potatoes, but this was not done and had not been suggested by the publication which mentioned the practice. In the meanwhile, so far as *raw* potatoes are concerned, my opinion necessarily is, that the plan of rearing orchards by cuttings inserted in potatoes may, for aught I know, succeed in Bohemia, but it wont do for Scotland. I do not recollect whether we made a trial with turnips instead of potatoes, although I remember we at one time talked of trying turnips. Most people are no doubt aware that there is a species of apple-tree which can be reared from cuttings, like a willow or a poplar, and produces sweet apples without engrafting. I have two of these trees in bearing. I got the cuttings from Mr. John Geddes of the Verreville Works, Glasgow. They were taken from a tree that had been removed from the college garden, and that tree was said to have been propagated from a tree belonging to the Monastery of Aberbrothock.* The apples are rather small, round, and may be eaten from the tree, being quite sweet.

NOTICE OF AN EXPERIMENTAL FARM IN FRANCE.

By Col. Le Couteur.

It is situated, in a beautiful and fertile country, well wooded and watered, but cultivated by the Breton farmers just as their fathers tilled it 200 years since. The college or experimental farm appears like a garden in a smiling wilderness, so far as culture goes. I rose at four in the morning, in order to witness the whole course of labor in this interesting institution.

There were from 80 to 90 students under the superintendence and tuition of a director, a professor of agriculture and agricultural chemistry, a veterinary surgeon, and an agricultural implement maker. At half past four they took a slight repast, and as the clock struck five, all were employed; some in harnessing the horses and oxen, others in carting out and properly disposing the implements in the field, others set to hoeing, others weeding, some ploughing, some hay making, in a word to all the various labors of the season.

* The Arbroath Oslin or Original Apple, here alluded to, is a well known variety. It may be added, that all the burr-knot and codlin tribes of apple-trees grow freely from cuttings.—EDIT.

The school is divided into working parties of ten; at the head of each is a steady young man of experience, called the 'decurion,' who directs the work of his party. In all difficult operations, a regular farming laborer is at hand to perform them; but such is the ardor and perseverance of the youths, that they rarely allow any difficulty to arrest their progress. The duty of one 'decury' or ten, is to dress, litter and feed the cattle, with as much regularity as a cavalry corps dress their horses; also to keep the farm-yard in order. Thus all, in turn, are made acquainted with every thing connected with a farm, whether in regard to horses, oxen, cows, pigs, or manures. These last are made and husbanded with the greatest care, the mixons being formed of sweepings, leaves, and weeds that had not seeded, in alternate layers with stable manure.

The drainings of the stables and straw-yard, run into a tank, to be pumped out when required as liquid manure, which is in the best, most portable, but least known in this country.

The learned professor M. Donku, who is an admirable practical farmer, as polite and communicative as he is learned, complained that he had not a sufficient quantity of manure. I urged him to burn the underwood and decaying timber of the large adjacent forests, through which wide roads were cut, which would enable him to obtain an inexhaustable supply of ashes the best of all manures either for turnips or wheat; the cartage of ashes being easy, and the quantity required to dress the land not being great; in which he entirely coincided.

At nine all come into their studies, when they write remarks on the various operations of the morning. From eleven to twelve is the breakfast hour. From twelve to three is the time for recreation and study, which embraces for the first class questions of the following nature:—"His farm of 600 acres, one eighth of which is always to be in beet-root, is to be divided into the most eligible rotation of crops; show the most profitable course, and describe the nature and chemical properties of the soil in each field, the proper manures to be applied to them, the quantity of seed required for the crop, its culture by previous ploughings, by after-hoeing or weeding, the cost and labor, and the probable return?"

The plans of farming given by some of the youths, would have done credit to an experienced farmer, and demonstrated clearly that though theory alone in farming is an absurdity, the combination of the practice with scientific acquirements, will soon operate great melioration in the agricultural world. From three till seven they prosecute their labor in the fields, being eight hours work in the day. They then come in for dinner. At eight the director receives the report, from every decurion, of the day's work of his party of ten. He then orders the work for the ensuing day, giving a concise lecture on the subject when necessary to the culture of any unusual crop. A library of agricultural works is open to the students till bed time, a quarter past nine. * * * The crop that appeared to me to be most carefully cultivated, was beet-root in drills, which produced per acre about 750 pounds of sugar, selling at ten pence per lb. as fast as it could be manufactured.

REMARKS ON THE EXCEPTIONS TO DR. MUSE'S ADDRESS.

To the Editor of the Farmers' Register.

March 25, 1838.

You will allow, if you please, an earnest patron of the "Farmers' Register," to make a few remarks upon your "Exceptions to some positions in Dr. Muse's Address," including, also, others of a similar import, under the signature of 'N. L.' in your late 10th and 11th Nos.

First, as to his belief of the transmutation of wheat—besides the numerous evidences referred to by him, he has lately received from a farmer of intelligence and high standing, other conclusive testimony.

What I chiefly design in this brief communication, is to call your attention to the fact, that your 'Exceptions' to Dr. Muse's views of the deterioration of our climate, and its approaching unfitness for the profitable growth of wheat, are founded, exclusively, upon *one, only*, of the grounds which he has taken to arrive at his conclusion, to wit: the *general* lowering of the temperature of the globe; and you consequently "differ widely as to the *rate* of the progress of the change." Were he to confine himself to this *single cause*, as you have done, he might probably agree with you, that the rate of the progress should be shown.

In his address, Dr. Muse has called in the aid of co-operative causes, which, he maintains, where they exist, will greatly accelerate the *ordinary* rate of this progress. Among these auxiliaries, he names the *extensive clearing of the country, and the felling of the forests of the United States*, which, from the geographical position of this section of the globe, in relation to the northern regions of the same hemisphere, and their mode of connexion, will, he thinks, in all human probability, upon well-known philosophical principles which he explains, produce such effects as he enumerates; and which, he thinks, have already operated to the injury of the wheat plant; and, as this cause is progressive in a kind of geometric ratio with the increase of the population, and the spreading of new settlements, so he thinks, that in a short lapse of time, not to be measured by a *single rule*, the meteorological character of the United States will be so considerably altered, not only in the *degree* of cold, but in the *suddenness* and *frequency* of the *transitions*, at all seasons of the year, and in the frequent and critical *droughts*, as to compel a resort to other crops, which may be found more suitable to the *partially present* and *reasonably anticipated condition*. And the motive of Dr. Muse appears to have been, not to excite alarm, or despondency, but to warn his fellow-citizens, of the necessity of gradually introducing new crops, in place of that, which experience and reason both declare to be on the decline.

You say, "if this (the general lowering of the temperature of the globe,) were the cause of the frequent failures of our wheat crops, the effect would be more striking, as we advanced to the *colder stations;*" which, you add, "is not the case." Dr. Muse adduces authentic proof, in the records of the "Northern Farmer" of New England that fifty years ago the New England states made fine crops of *winter wheat;* and that now, they cannot produce enough of this grain to pay costs." They are, at present, trying the *spring* wheat, to avoid the effects of their modern winters; and much to the honor and sagacity of that section of country, under the encouragement of *legislative patronage.* Many of the northern and eastern states, from the same necessity, have, with legislative assistance, also introduced new crops, in place of the wheat; and, with acknowledged advantages to the public and private wealth and convenience. A similar policy has been adopted in Europe, in regard to both *new crops and spring wheat,* with good effect; and this is a point which Dr. Muse was obviously desirous to demonstrate the necessity of attaining, for the safety of Maryland agriculture, whose legislature have uniformly refused any participation or regard for the interests of this branch of industry.

Moreover, Dr. Muse in his address, admits that *other causes,* as well as *climate,* may conduce to the extensive failure of the wheat crop in the south, as well as the north; such as the migration of parasitic insects to their choice plants :and this cause should show its effects as strikingly, if not more so, in the *warmer,* than in the "*colder stations;*" because, in the former, this class of animal evils is generally the most abundant; and this may be one great cause of the frequent failure of southern wheat.

The general scope of my remarks will apply equally to some of the 'Exceptions' taken by your correspondent 'N. L.' to the same address.

He ascribes the failures of the wheat crop, to the want of a "*fit soil*" and "*good culture,*" "rather than to the want of a *suitable climate.*" The general *fitness* of the *soil,* cannot materially have differed in its constitutional character, and the "*culture,*" under the advantages of science and experience, and increased devotion to this branch of industry, for the late and long term, in which the failure has been occurring, must be obviously better than formerly. These two propositions being, it would seem, undeniable, the climate must be held largely answerable for the defect.

Indeed, it does not seem reasonable to entertain the idea, that a whole class of men, possessing *now* more knowledge of principles and practice than *formerly,* which must be conceded, as having grown out of time and experience; and, having equal, if not larger interests at stake, as well as improved implements, should execute their work with less skill, judgment, and attention, than their ancestors, who did not possess them.

Your correspondent 'N. L.,' adduces the successful growth of the Cuba tobacco by Dr. Muse, as evidence of the power of acclimation, and against his position, that plants should be brought from higher latitudes.

This very article affords good proof of the correctness of Dr. Muse's position, "that plants from the north will be more likely to continue longer with us." Gen. Hernandez and others, entitled to full confidence, assert the fact, *upon trial,* "that the Cuba tobacco, though very fine, from the imported seed, grown in the southern and middle states, will very shortly degenerate *by reproduction,* and not be recognized as the same article, differing so widely in its structure and qualities, &c. &c. it would seem to furnish an instance of transmutation, almost as considerable as that of wheat into cheat.

AGRICULTOR.

From the British Farmers' Magazine.

ON GREEN CROPS—THEIR USES AND CULTIVATION.

Most of the arts and sciences during their progress from infancy to their present state, have been greatly advanced by some single discovery which has accelerated their progress much beyond what might have been expected during a long period of years, and has introduced a new era in the history and application of the art. The invention of printing greatly facilitated the progress of all improvements; and has spread knowledge and civilization to the remotest corners of the world; the discovery of the magnetic needle, altered entirely the system of maritime intercourse; and the invention of gunpowder completely changed the whole art of war, and introduced an entirely new system of tactics, more simple and direct, bringing the strength of nations more nearly to a level, and has rendered war less bloody, and success to be more nearly a matter of calculation. In our present time, the invention and application of steam power to arts and manufactures, and the substitution of it for animate labor, will mark an epoch in the history of machinery, not less interesting or less useful than any of the great discoveries which have so much benefited the human race; and the prospects we may reasonably entertain of its future developement, lead us to indulge in the pleasing hope, that the uses of this wonderful power, in simplifying the production of the necessaries of life, are many of them still unknown, and will lead to useful and valuable applications. The introduction and cultivation of green crops, for rearing and feeding the different animals used by mankind, has constituted an era in the history of agriculture, similar in its nature and results to the many discoveries that have flowed from the labor and ingenuity of man, and which have contributed so materially to the amelioration of the different conditions of society. The introduction of these crops in districts where cultivators have had the penetration to discover their utility and value, has completely overturned the mode of farming practiced for centuries—the value of land has been much increased—immense fortunes have been realized, and a better and more regular supply of all kinds of human food, has been provided at profits amply remunerative to the cultivators and owners of the soil. Nearly two hundred years elapsed after the potato was known, before it was cultivated in the field: and notwithstanding the ravings of Cobbett, and the aversion yet shown to its growth as a scourge of the soil—it may be affirmed, that this island is not blessed with any root more valuable, or of more general use, from the table of the grandee to the feeding of pigs and poultry; or with any esculent which will more amply repay the cultivator for his pains. Upwards of sixty years have now elapsed since turnips were cultivated, their uses known and value proved; yet at this day we find many places where they are little known, the cultivation neglected on account of expense, and recommendations yet given by periodicals to farmers, of a plant of long establishment and of acknowledged value. The method of cultivating these crops, the preparation of the land, and the application of manure, and the subsequent management, have been so often described in different publications, that I need not state them in detail; and shall only observe, that the dispute betwixt the methods of drilling and broad-casting may be resolved, by simply stating that the former method has been long adopted by the most extensive cultivators, and by the Earl of Leicester* himself; and that if the additional expense incurred had not been repaid, it must have been ere now discovered and abandoned. Experience also shows that all manures applied to turnips should be heated, and in a state of decomposition, so as to afford immediate support to the plant; and that expense has often been uselessly incurred in reducing putrescent manures to a cold mass, though as good a crop may be ultimately obtained, if the season and the fly have spared the braird, and allowed time for the plant to reach the manure. Of all the inventions in shape of auxiliary manures, none yet discovered can be compared with crushed bones, both in point of cheapness and efficacy: good crops of turnips are raised for 20s. to 40s. an acre—one half, and, in some instances, one-third the cost of putrescent manure. The lightness of carriage is a great consideration, a four-horse wagon carrying a dressing for ten acres, allowing one and a half to two tons per acre. Though the value of this manure has been completely established many years ago, it is very remarkable that no use has been made of it in places most favorable for the application. Bones are sold in London at 2s. per bushel: great quantities are carried by sea to Scotland, and sold at 3s. 6d., and even 4s. 6d.; cattle are fed with turnips raised by the bones, and sent back to London at an expense of £3 a head, and the farmer pays £2 to £4 an acre for the land. This is an anomaly which I think will puzzle Mr. Cayley, with his pockets crammed with one-pound notes, to explain. The London farmer has bones at nearly half price, suitable soils, an early climate, and excellent markets; but he cannot divest himself of the idea of expense he pays in the bill for bones, small as it is: no bill is presented for farm-yard manure, and he consequently thinks it costs him nothing. Drilling at 26-inch intervals appears a waste of land; he drills at 10 or 12 inches, and gets an inferior crop. Turnips are universally applied to rearing and feeding cattle and sheep—the former in stalls and yards, both for feeding the animal and for reducing the straw to manure—the latter on the land on which the turnips are grown. On sands, as in Nottingham and Norfolk, sheep can eat turnips dry and clean; but on wet and poachy loams, on which our best crops of turnips are grown, during rains and thaws the sheep stand deep in mud, having the wet land to lie on, and the turnips dirty and unfit to be eaten. In such cases, I would always prefer to have the turnips carted to a clean lea or stubble field adjoining, where the turnips may be regularly spread, and the sheep have a dry bed and shelter at pleasure. The fields will have the same advantage in this way as in the other—each field being regularly fed on in stubble or in grass.

Notwithstanding the very general use of potatoes, an antipathy prevails against their growth, and some proprietors restrict the farmers from planting beyond a supply for their own use. This absurd prejudice has got deeply rooted; I never could see a green crop impoverish land, and persons who have made this discovery must have clearer perceptions than I can claim. On loams worth 30s. an acre, I have ever found 10 tons an acre, 5 quarters of wheat, and heavy crops of clover, equal, if not superior, to those after turnips; in some places the better crop is always expected after potatoes. Of all green crops they are the most valuable: of surer growth than turnips or beet, and capable of being raised on a greater variety of soils. A part of the crop being sold, the other must be consumed by stock pigs, and poultry, now rendered more economical by steaming. On many soils, turnips are a precarious crop; an indifferent crop of potatoes is equal to a heavy crop of turnips; the same quantity of putrescent manure, with less preparation, will raise the potato crop, and when consumed on the farm, it will produce the same quantity of manure. Comparing quality with quantity, we find that potatoes (Hortus Gramineus Woburnensis, page 388,) yield much more nutritive matter per acre, than any other esculent; one-third more than carrots, twice as much as ruta-baga, and nearly three times as much as white turnips and mangel wurzel. If an ox eat a bushel of potatoes a day, at 1s. 6*d*., and an equal value of Swedes, it will follow that the ox fed on potatoes will eat double the quantity of nutritive matter, and ought to make double progress in the process of fattening; and that an acre of potatoes should feed nearly three times as much stock as an acre of turnips. But experience has not been found to support these refined calculations of Sinclair, however chemically correct they may be; but it may be taken as a fair statement, that a crop of potatoes of 400 bushels is double the value of the best crop of Swedes; affords twice as much nutritive matter; and, consequently, should keep twice as much stock. In the Quarterly Journal of Agriculture, June, 1834, we find statements of the results of trials in feeding on raw and steamed food, which are conclusive in favor of the former in feeding cattle, and of the latter for pigs; and we find 140 lbs. of turnips and 84 lbs. of potatoes, yielding nearly the same increase of beef, keeping the relative value as 2 to 1. These trials proved also that raw potatoes alone will feed cattle, which has been much doubted by many eminent farmers, and seem decisive in favor of raw food for feeding, exclusive of the expense of steaming. In the vicinity of towns and villages, there is always opportunity to carry back manure for the quantity sold; in inland situations they must be wholly or nearly consumed by stock. A turf of weeds is, however, much preferred to such crops; and if a proprietor be at any time induced to plant potatoes, he is soon warned of the destruction of his property; and generally such foolish prejudices weighed against the best crops in the kingdom make the latter kick the beam. Nothing in connexion with agriculture ever adpeared so amusing as to hear prejudice discussing the state of cropping and the relative merits of plants; when just as ignorant of the facts as the quill with which it wrote; and forbidding the culture of potatoes as a scourge.

On stiff soils, not adapted for turnips, mangel wurzel has been cultivated with considerable success. Sinclair states, that an acre of potatoes of 10 tons is equal to 25 tons of beet in nutritive mat-

* Lately the great *commoner* Coke of Holkham.
ED. FAR. REG.

ter, and that an acre of beet affords double the weight per acre of rutabaga, and the nutritive matter in the same weight being nearly equal, an acre of beet should feed twice as much stock as an acre of Swedes, and as much as an acre of potatoes of ten tons. On loamy clays, great quantities of winter food may be produced from beet and cabbages; and experience has shown that fair crops may be obtained on more indifferent soils, and with less manure than general opinion understands. White turnips and cabbages will feed through November and December, then beet and Swedes will serve till the end of June. I have been some time of opinion that cabbages, beet, and potatoes are often too late in being planted in the spring; and that the crops are much hurt by being exposed to the hot suns of summer before they have attained sufficient strength, and before they have produced a shade by their leaves to retain moisture and protect the roots against the influence of that scorching element. The objection is, that these stiff lands cannot be got ready sooner in the spring; but this might be remedied by preparing the land the previous autumn, and laying it dry during the winter. When I visited the Duke of Portland's farm at Welbeck, in 1834, I much admired a field of heavy loam prepared and drilled up to be planted with cabbages in the following spring. This must be a great advantage; the dung may be applied during the first dry weather; the drills reversed: a fresh tilth is thus produced for immediately planting the crops. The cabbages might be planted in autumn, but would certainly be destroyed if near a preserve of game; and if the manure were applied in autumn, it might be wasted before the roots of the plants come in contact with it. Winter and spring vetches rank high in the scale of green crops, and are either eaten on the ground by sheep, or cut for stall feeding. As to eating on the ground, I am of the same opinion as in the case of turnips, and would always prefer to have the tares cut and eaten in the racks. As tares can be grown on damp soils, the sheep trample and waste a quantity, which will amply pay the expense of cutting and racking, and the animals will be more comfortable. Tares are invaluable as green food for horses in well-littered yards: manure may be obtained in great quantities, if proper yards be provided and litter amply supplied. But if all green crops were raised in profusion, the full value never can be obtained, until farm buildings undergo a complete revolution; for we must call it farming when we see one or two large yards and the straw blown about by the wind, the moisture of the whole farmery running on the road, or forming a useless stench-pool behind the yards. Even in the most complete plans of farmeries, furnished by our best modern publications on the subject, we find little or no attention paid to the accommodation of swine, those excellent manufacturers of manure. They run about at pleasure, and lie where they can find a corner; and on farms of 500 acres only one or two sties are found. In place of such neglect, I would have a large square or circular yard, with sheds appropriated for store pigs sunk at least two feet below the adjoining level, and regularly and deeply littered with straw, firm, and alternate layers of any vegetable substances that can be got; the yard being first bottomed with a thick stratum of loamy soil from old fences, head-lands, and ditches. Around this yard, and with back doors opening into it, may be ranged a number of sties for breeding and feeding; the store pigs in the yard to be amply supplied with clover and tares during summer, and during winter with beet and cabbages, turnips and potatoes. Abundance of litter is indispensable; and if it be objected, as usual, that it is expensive and will not pay, it is difficult to know what will pay; for by increasing manure produce is increased, and without produce profits cannot be got. Rye and rape are much sown as catch crops, in the southern counties, for sheep feed, and on suitable soils they supply a bite when most wanted, from a deficiency of the heavier crops. But being usually sown from want of manure, and for feeding on the land before a regular crop, they do not enter into the number of the cultivated green crops.

In order to extend the cultivation of green crops, draining is a primary and indispensable requisite. From want of this operation much of the value of the dung and lime now applied on retentive soils is lost; and were it effectually performed, the number of acres capable of producing green crops would be greatly increased. But we see hundreds of acres very suitable for such crops that have never been employed in that way, and it may be very justly observed, that the cultivation of these soils might be expected to precede the improvements by draining wet lands at a very considerable expense. This neglect shows the most culpable negligence: the production of such crops on drained lands might tend to rouse from their apathy the owners and cultivators of these neglected soils. The system of tile draining was introduced some years ago by the Duke of Portland, on his estates in Ayrshire, in Scotland, where it has been attended with very beneficial results. The climate of Ayrshire is one of the wettest in the kingdom; the soil is mostly loam, or loamy clays, on a bottom of the most obdurate and impenetrable clays anywhere to be found. The drains are in the furrows, or at regular distances, and the land flat, twenty-four inches deep, and covered above the tiles with straw and porous earth. The tenant performs all carriages, and the draining is executed by the proprietor, at an expense of about £5 or £6 per acre, according to the breadth of the ridges, for which the tenant pays 5 per cent. or 6s. an acre, nearly. At the end of a lease of twenty years, the capital is repaid, and the land much improved in value; for it is confessed by the farmers themselves, that they have now four crops for three before, in three years, wholly owing to the cultivation of green crops after draining. Here is a great and lasting improvement effected without the aid of the Chancellor of the Exchequer, and forms a valuable contrast with the vapid declamations of dinner orators about the currency and one-pound notes. The produce is increased to pay the tenant's outlay; the proprietor has a regularly paid interest—a sure investment for his capital—and the land to be let at a highly improved value. The enabling a farmer to grow heavy crops of potatoes and cabbages on clays where no attempt could be reasonably made previously on such soils, is the true way to benefit the farmer, and not to delude him with glittering oratory and visionary projects, which never advance beyond the speaker's lips. This system of draining is extending in East Lothian, and in many cases is performed by the farmers themselves; and some similar system has been adopted by Sir James Graham and a few others. To follow this mode of draining, a subsoil plough has been invented, to move the soil a foot below the ordinary furrow, in order to deepen the mould by the gradual mixture of the soil and subsoil. This is in direct opposition to customary practice, which fixes wheels on the beam of the plough to prevent going too deep; so contradictory are the opinions of men. But reason tells that whatever tends to deepen and increase the quantity of soil, will increase its fertility; and that in order to afford food to plants, the soil must be moved and brought in contact with the roots. In order to promote this object, complete pulverization is essentially necessary, and a minute mixture of the soil with the manure applied; for we know enough of the nature of the food of plants, to conclude that it must be in a state of solution and most minute subdivision. The reducing putrescent manures to a cold mass has been doubted, and is now partly discontinued; but it may still be doubted, if straw and excrementitious matter, though heated and in a decomposing state, lying in a body along a drill, be in the best state capable of affording nourishment to the tender roots of plants. This idea occurred to me in 1827, when, in order to complete the dunging of a fallow field in Northumberland, I applied some very rough manure, almost dry straw, on two acres on a side of the field. The ploughs could not cover it, and the appearance was very unsightly. The field being clear of weeds, the dung was applied in July, and was much pulled about by the ploughing, one extra furrow being given to the two acres, to cover the dung, if possible. When seed-furrowed in October, the soil and manure appeared finely blended, the braird matted flat and thick, a sure sign of prosperity; and to the day of reaping maintained a very visible superiority over the rest of the field. It is now generally understood to apply rough dung evenly over grass lands; to bush harrow, roll, and rake the refuse—great part of the benefit to the grass arising from the temperature produced by the covering of dung. To apply rough dung from the yards to fallows clear of weeds and early in the season, so as to admit of repeated ploughings and harrowings, seems practicable in many cases; but to apply it to Swedes and early sown crops, when the land may require repeated cleanings, and when the season affords fewer opportunities of mixing, admits of more doubt. To settle this point, and to determine if dung so applied and blended, on land prepared in autumn or in spring, would afford equal crops of turnips, beet, or potatoes, with a mass of dung lying in drills, would be a curious and a most valuable experiment. To apply rough dung from yards and sheds to raise turnips, on which so much labor is bestowed in preparation, will seem a most startling doctrine; but let not conceit and ignorance condemn such suggestions, for every improvement has had a similar origin: and if experience confirms it, it will be an improvement of the right kind—to produce a result at less cost. Experience has convinced me that a farmer may plough and sow and reap for his lifetime, and derive no advantage—very probably impoverish himself and his farm; and that the first and most essential requisite is to fill the land with manure, by every possible means; and if the land be then kept in that state by judicious and improving rotations, return and profits may be confidently expected. A farmer may hire a farm, stock it with seed and a few implements, sow and reap and get little; but unless every exertion be used to increase the means whence the produce flows, he will only resemble a manufacturer who erects machinery, and then refuses to buy the raw material to employ it. A miller must buy a quarter of wheat before he can expect the profits of manufacturing it: the cotton spinner must buy the raw material before he can reap the profits of his machinery: in like manner the farmer must buy the basis of production, or he will drudge and puddle on as he has done, in confusion worse confounded.

In the Quarterly Journal of Agriculture, Dec., 1836, we find a review of Mr. S. Lefevre's letter, on the result of the labors of the agricultural committee, passing over much of the inquiries about the foreign and domestic prices of corn, and other matters of little use. I shall make a few remarks on the expenses of cultivation, as connected with my present purpose. The relative expense of cultivation is stated as differing 45s. per acre on land rented at 39s., being more than the rent of the land. In the review we find the following passage:—"If the expenses are not calculated on similar data, there can be no analogy in the results; and even if they had been so calculated, the comparative industry in the application of labor should not be overlooked. Calculating corn consumed by men and horses, and in seed at market price, and the price of labor as if paid by the day or job, can give none but fallacious results. A farmer has no right to estimate the cost of these items of expense at more than they really cost him." This comparative industry, in the application of labor, constitutes the difference of expense, and it seems in this case we must put down 45s. as that difference. The industry used in any art, will show itself in the superiority of the execution; and, by here allowing 45s. in superiority, a balance will be struck. It is a general complaint of farmers, that all crops cost more in cultivation than they receive for the produce: if, therefore, the farmer cultivates these items at the market prices, he estimates at less than they really cost him, and not at more, as stated in the review. The grand objection always found against the convertible system, is the expense. Here is an open uncontradicted statement in an open committee, of less expense in support of private statements, which are always disregarded, and proprietors asserting they cannot support a system that pays most rent. And it seems as if no statement, even Mr. Lefevre's, will be convincing; for an Athanasian creed has obtained in the field as in the temple: Do as we do, say farmers, and you will be right;—if you do not, you are wrong. Many ludicrous opinions have been advanced to account for the superiority of the alternate system. Mr. Poulett Scrope says it is the freedom from tithes and rates; and then reckons them all as rent. One sentence, here, being a flat contradiction to the other, does not require any further confutation. Mr. Cayley is certain it is the possession of one-pound notes, as they make capital more plentiful for undertaking improvements; and, from analogy, they will also make money more plentiful for prices of produce. Now, in this case, produce of every kind is grown in a country abounding in capital, and sent to another, where it is scarce, and finds higher prices. An ox is fed on a depreciated currency, say for £15; he is sent to London, and fetches £20 for expenses and profits, and in gold, and more than can be got in one-pound notes at home. If capital be wanting to raise the ox, whence comes the capital to buy him? Would not the price raise him at home? Gold has reared the ox, and gold has bought him. When one-pound notes were in circulation till 1819, cultivation was no better, and complaints were as loud. The truth is, if Mr. Cayley and others will hear the truth, it is merely an application of capital and labor to the increase of produce under a different system. How one-pound notes can make a good ploughman or mechanic, is certainly difficult to conceive. Manufacturers reckon profits by the quantity of goods they can produce, and commercial dealers by the amount of their transactions, and every corner of the world is explored to find an opening for the increase of trade in farming; prejudice and monopoly restrict the quantity, to a certain amount, arising from an established system that must not be disturbed, and then prohibitions and restrictions are enacted to impose a factitious value on that quantity.

On the much-disputed point of preference betwixt wagons, and single horse-carts, the writer of 'British Husbandry' prefers Mr. Parkinson's single opinion to the practice of half the kingdom. Where the drill system prevails, these carts must be used to suit the drills, and wagons are useless. Abroad, the carts will carry more than wagons; and, judging by a majority of similar results, the usual criterion in such cases, the superiority is incontestable. I remember seeing a farmer, in Surrey, ploughing a sandy loam with a turnwrist plough, four horses, a man and boy, at 15s. a day, and ploughed three roods. Two horses, with an iron plough, would surely have ploughed an acre in nine hours: here are 10s. against 20s.; or, if the four horses had ploughed an acre, there are 10s. against 15s. The answer would be, that labor is diminished by dispensing with the boy; this is just what is wanted, the value of his labor not being required to produce the result of ploughing an acre in a day, remains to be applied to another point. We have lately had a description of a grass yielding 30 tons an acre, by the Central Society of Agriculture; of a newly invented machine to do away with the malt tax; and with a universal remedy for agricultural distress, in the shape of manure, to be gathered in tanks from the water of the common sewers in London. Laying prime cost aside, the expense of carriage to a distance must be considerable; and how it is to be got in quantity and conveyed at a rate to remedy the whole complaints, is a question not so easily answered. The circumstance of proprietors and cultivators forming a society to advance the state of agriculture, and at the same time neglecting all improvements, leaving lands undrained and totally neglected, and actually forbidding any alteration, is certainly an anomaly not often surpassed in the anomalous history of mankind. It might be curious to inquire, if there be shown by the Society as an improvement, a piece of old turf, covered with weeds, with the veto attached—"This must not be ploughed or ————*, but remain as it is." Drilling is reckoned unnecessary labor—thrashing by machinery is not customary—breeding and feeding young stock is fancy farming—and ploughing old turf is complete madness; —draining is too expensive, and perennial grasses, though constituting the best pastures growing naturally, become an absurdity, and little better than weeds, when sown to make a sward. All known improvements being rejected and hunted down, it is difficult to see by what means the art is now to be benefited. Many improvements have been long known, and lie dormant from want of execution: the proficiency of any art, and the superiority attained in it, must depend on the skill and assiduity of the practitioners; a good article always brings a higher price, and consequently its own reward; and, provided each branch of business have fair scope, and be not unduly fettered, the different methods of practice must sink or swim by their own merit.

GOVERNMENT BOUNTIES TO AGRICULTURE, AND TO PRINTERS.

We have just received from Washington a pamphlet of 99 closely printed octavo pages, consisting of a report of the Committee of Agriculture, and various accompanying documents, all serving to detail, and to recommend to the favorable notice and patronage of congress, the plans and labors of Dr. H. Perrine, for introducing the cultivation of valuable tropical plants into the southern part of Florida. It may well be doubted whether any profit will accrue to any person from this publication, except to the public printer, for printing the usual number, and also 5000 extra copies of this large pamphlet. But we wish it may be otherwise Dr. Perrine has no doubt made great efforts to introduce tropical plants into Florida, and not less, nor long, to induce congress to assist and reward his labors; and, as yet, his efforts in both respects seem to have been nearly fruitless. His scheme, if carried into effect, may or may not be productive of great improvement to southern agriculture. But, doubtful as may be the direct benefit, we should rejoice to see some portion of the enormous squanderings of public treasure by the government of the United States, directed, even though but in design, or but nominally, to the object of agricultural improvement; as merely the principle being adopted, and its application commenced, might lead, finally, to a beneficial system. Dr. Perrine asks for a township, 23,000 acres, of public land, on the southern extremity of Florida, to repay his expenditures, and enable him to effect his objects of introducing and acclimating tropical plants. For this, or for any object likely to forward national improvement, congress would make a good bargain to give away not only the 23,000 acres, but the whole of southern Florida; provided the receiver would take its troublesome inhabitants, the Seminole Indians, as part of the grant. The present market value of a tract of

* The original being written with a lead pencil, and having been rubbed at this place, we are unable to make out the word.—Ed.

the size asked for by Dr. Perrine, is probably not more than the cost of public printing already wasted (if leading to no further action than merely paying the printer,) in publishing the documents sustaining the petition. Indeed, it would be a provision for Dr. Perrine, with which he might well remain content. if congress would merely pay to him as much money as has been, and will, without scruple, and as a mere matter of course, be paid for printing and circulating his memorials and documents. The printing of this single pamphlet must have cost more than congress probably would grant directly to aid the true improvement of agriculture. A less sum, for establishing a Board of Agriculture, the legislature of Virginia refused, and with so much slight and contempt, as to leave no ground for any advocates for agricultural improvement to ask again for legislative aid or bounty.

After the foregoing paragraph was in type, we received from Dr. Perrine a second pamphlet, of the same purport and substance, though not in precisely the same form, being the "Report of the Committee of Agriculture" to the Senate of the United States on his petition, with accompanying documents. This publication, though in pamphlet form, would be a bookseller's volume, of 142 pages letter press, and 24 more pages of well executed and handsome copperplate engravings of various tropical plants referred to by the petitioner; and of this, also, 5000 copies were printed, in addition to the "usual number" of congressional documents. This is not only, probably, of double the cost of the other publication spoken of above, but both of them are but second editions, revised, corrected, and enlarged, of prior publications, made in like manner by order of congress—and which course of annual publication will continue so long as Dr. Perrine shall continue to present his claims, even though he may fail to obtain one dollar for the benefit of himself, or his plans. What we before supposed to be probable, is now placed beyond doubt, viz.: that the mere cost of printing his documents, if paid directly to Dr. Perrine, would be certainly equal to the value of the township of land in Florida for which he asks. And, if he could even get half as much as the clear profit of the printers of his documents, he would find the business of petitioning annually more profitable than we fear he will in other respects; and the amount gained greater than any legitimate and honest appropriation that will be made in aid of the objects of his petition.

Some novices in the knowledge of congressional economy, may wonder why *two* such voluminous publications of the same character, and form so nearly similar, and in editions of like size, should be published at the same session of congress; inasmuch as nearly half the expense might have been saved by printing the whole number even of the larger work. But if this cheaper course had been pursued, *one* only of the two public printers would have had a fat job, whereas now one has been given to each of them: and this is an object more cared for, and far more cherished, than either the emoluments of Dr. Perrine, or the diffusion of agricultural information, and the consequent improvement of agriculture.

We copy below the 'Report' of the Committee of Agriculture of the Senate; and heartily wish that its general recommendations and objects may receive from both houses of congress as much favor, and public bounty, as the subject has already served to furnish of profitable jobbing to public printers, and of expenditure of public money, useless except to these government pensioners.

REPORT TO THE SENATE OF THE UNITED STATES ON DR. PERRINE'S PLAN OF INTRODUCING TROPICAL PLANTS.

The Committee on Agriculture, to whom was referred the memorial of Dr. Henry Perrine, late American Consul at Campeachy, praying for a conditional grant of land in southern Florida, to encourage the introduction and promote the cultivation of tropical plants in the United States, have had the same under consideration, and beg leave to submit, to the consideration of the Senate, the following report.

At the express desire of the memorialist, your committee has long delayed its action for the purpose of making a rigid investigation of his suggestions, his services, and his plans, in relation to the immediate domestication of tropical plants in southern Florida, and of their gradual acclimation throughout all the southern and southwestern states; and hence your committee has arrived at the conclusion that his services have been great; that his suggestions are important; and that his plans are laudably patriotic and practicable. In obedience to the treasury circular of the 6th September, 1827, Dr. Henry Perrine appears to be the only Americal Consul, who has perseveringly devoted his head, heart and hands to the subject of introducing tropical plants in the United States; and his voluminous manuscripts alone exhibit a great amount of labor and research, which promise to be highly beneficial to our common country. The memorialist founds his hopes of final success for the immediate propagation and subsequent cultivation of tropical plants in Florida, on four leading facts: 1. Many valuable vegetables of the tropics do actually propagate themselves in the worst soils and situations, in the sun and in the shade of every tropical region, where a single plant arrives by accident or design. 2. For other profitable plants of the tropics, which require human skill or care, moisture is the equivalent to manure, for tropical cultivation essentially consists in appropriate irrigation. 3. A tropical climate extends into southern Florida so peculiarly favorable to human health and vegetable growth, that the fertility and benignity of its atmosphere will counterbalance the sterility and malignity of its soil. 4. The inundated marshes and miry swamps of the interior of southern Florida are more elevated than the arid sands and untillable rocks of the coast; and hence the same canals which may drain the former will irrigate the latter, and afford the appropriate proportion of moisture for both. The memorialist founds his hopes of success for the *gradual acclimation* of many profitable plants of the tropics, throughout at least all our southern and southwestern states, on, 1st, The general history of all tropical plants whose cultivation has been gradually extended towards the poles. 2d. The particular history of our actually great staples of the south and southwest, viz.: tropical rice, tobacco, cotton, and sugar; and 3d, The fact that kindred species of many profitable plants which will be still more important objects of *agriculture*, are indigenous to our worst soils between the Potomac and the Mississippi, viz.: of Agave and Yucca. In relation to the extension of a peculiarly favorable climate of the tropics into southern Florida, your committee believes that the memorialist has demonstrated its existence by the meteorological tables annexed to this report. In relation to the immediate propagation of tropical plants in tropical Florida, on the most arid, the most humid, and hitherto most worthless soils, your committee believes that the memorialist has shown its great probability by the interesting facts and statements made and collected by him, and which are annexed to this report. And in relation to the gradual acclimation, at least the fibrous-leaved plants, whose foliaceous fibres are superior substitutes for flax and hemp, your committee coincides with the memorialist in his opinion, that the tropical species may gradually extend over the most steril districts of all our southern states, and that the indigenous species may be gradually propagated in the worst soils of our northern states. Hitherto, southern Florida has been considered so sickly and so steril as to be unworthy the expense and trouble of surveying and of sale; and, even now, it is seriously contended that this section of the Territory is uninhabitable by the white man, and should, therefore, be abandoned to the savages and runaway negroes from the neighboring states. At all events, it is conceded that many millions of acres are incapable of producing any article now cultivated in the United States, and must lie unemployed and useless for many years, without some experiment such as Dr. Perrine proposes. Hence, when the Indians shall be expelled from the pestilential swamps and impenetrable morasses of southern Florida, they may again become the impregnable fortresses for fugitive negroes and practical outlaws, who will be still more dangerous enemies to the tranquillity of our southern states than the actual savage Seminoles. But if the suggestions of the memorialist, and if his experiments should be successful, the arid sands and arid rocks, and mangrove thickets of the coast, the miry marshes, pestilential swamps, and impenetrable morasses of the interior, may all, ultimately, be covered by a dense population of small cultivators, and of family manufacturers; and tropical Florida will thus form a well garrisoned bulwark against invasion in every shape and shade. Even the statistics of Cuba demonstrate that this celebrated island owes its prosperity and its safety much more to its numerous small cultivators of fruits and vegetables, than to its few large planters of sugar and coffee; and hence it may be considered fortunate for all Florida that its southern surface does not embrace any large tracts of rich soil adapted to the great staples of great planters. Hitherto, the old southern states have been drained of their rural population by the emigration of their sons to the fertile plains of the valley of the Mississippi and Ohio. By the introduction of such new staples as can be propagated, on the worst soils of the old states, more profitably than their old staples can be cultivated on the best soils of the new states, emigration from the south will be prevented, and even its ruined fields and barren wastes will become covered with a dense population of small cultivators; and that rural population may be tripled by the employment of new staples in the really domestic manufactures of their farms, families, and females. At all events, the numerous small cultivators of the south would thus be enabled to furnish the cheapest possible raw materials for the numerous small manufacturers of the north, and would hence create, mutually, a profitable and harmonious dependence on each other of the great pacific masses of population in both sections of the Union. With these views of the national importance of the enterprise of Dr. Perrine, your committee have determined to report a bill, on such conditions as will render it barely possible for him to attract associates and capital to the aid of his future labors, with unity in design, harmony in co-operation, and perseverance in pursuit. Under the conditions imposed, he only hopes to get co-operators among those patriotic persons, who will be influenced by the facts, arguments, and feelings which convinced his own mind of the great probability of ultimate success, and which, therefore, renders him willing to undergo all the intermediate privations and perils of property and person incident to the prosecution of the enterprise.

In other countries, an undertaking of such magnitude is the especial duty of the government; but, in the United States, we are indebted to individual zeal and perseverance for the origin and prosecution of the grandest plans of national utility.

On the 26th of April, 1832, the Committee on Agriculture of the House of Representatives reported a similar bill; and your committee now refer to the accompanying report and other documents. Your committee need not dwell on the services of the memorialist, nor recite the precedents of equivalent grants to foreigners, as the memorialist is content to rest his claim solely on the merit of the enterprise, with the facts that by the terms of the bill now reported, if he succeed, the government and the country will be benefited in the proportion of a thousand to one, and if he fail, himself and his associates will be alone ruined. From the specimens of fibrous-leaved plants and of foliaceous fibrous submitted to your committee, they are convinced that if those plants alone can be propagated in southern Florida, of which they have no reasonable doubt, they will form highly important additions to the agriculture, manufactures, and commerce of the Union. The committee annex to this report several explanatory letters and other important documents, from one to four.

INTRODUCTION OF TROPICAL PLANTS.

[The following communication from Dr. Perrine, arrived after the foregoing pieces, on the same subject, were in type.]

To the Editor of the Farmers' Register.

Washington, D. C., 11*th April*, 1838.

Sir—Five days since, the subscriber had the honor to direct to you a copy of the 'Report of the Committee on Agriculture' of the House of Representatives, accompanying the bill to encourage the introduction, &c. of tropical plants; and he now has the pleasure to transmit you a copy of the 'Report of the Senate Committee' on the same subject. Besides the usual number of 1114 copies of each Report, 5000 extra copies were ordered to be printed; and the subscriber, at his own expense, has purchased 100 super-extra copies of each, from which are taken those presented to you. The subscriber is firmly convinced, that if congress were to pass a general law to grant all southern Florida on the terms of the bill for one township alone, not a single settler would accept a single section on condition of the successful introduction and cultivation of new and valuable staples of agriculture, adapted to the most sandy, swampy, and steril, or hitherto unproductive and worthless soils. Although it has been reaffirmed by all persons experimentally acquainted with southern Florida, that it is uninhabitable by the white man, and hence not worth even the medicines of the soldiers necessary to conquer it; yet the mere fact of the petition of the subscriber for a conditional grant to experiment the correctness of his theory, that the benignity and fertility of the climate will counterbalance the malignity and sterility of the soil—the mere fact of asking for the power of location in this reputedly uninhabitable region, is supposed by suspicious indolence and by jealous ignorance, to indicate that I must have discovered some mine of treasure in a six miles square of country never seen by the subscriber. The subscriber believes firmly in the truth of all the official reports of the sickliness and sterility, and absolute worthlessness of the soils of southern Florida; yet in the 'Reports of the Committee on Agriculture' of both houses of congress, you will see developed the leading facts on which rest his hopes of success for new staples of the tropics within tropical Florida. At all events, the subscriber has not yet encountered any intelligent agriculturist who does not agree that the interests of the government and of the nation would be promoted, by ceding all the worthless public lands, on the terms embraced in the bill for a single township, or the forfeiture to government, within eight years, of every section which should not be successfully occupied and cultivated with new and valuable staples.

It is presumed that every disinterested statesman would at least go so far as to admit, that the government should cede, at the least, one-half of all its *unproductive* lands, on similar conditions, since every other government in the world cedes all its most productive soils to actual cultivators. The subscriber confidently entertains the hope, that if you give due attention to the documents aforesaid, you will give a corresponding support to the enterprise, as he wishes only that kind and degree of aid, which investigators of the subject may consider due to its merits. He has no fear of open hostility from any personage, either in or out of congress, who shall have previously taken the trouble to make himself acquainted with the length, depth, breadth, and bearing of the topic. His only apprehension is from congressional delay—delay—delay already extended to six years since the first bill was as unanimously reported as the last have been. By noticing the proceedings of the agricultural societies of New Orleans and of Charleston, and the resolutions of the legislature, you will be able to decide whether your influence could be beneficially exerted in a similar way, or whether it may be more profitably directed to individual members of congress, with the sole view of having the bill taken up the present session and passed into a law, or entirely rejected, on its merits or demerits, whichever may seem to predominate, after a fair, full and free discussion.

H. Perrine.

[Document annexed to Dr. Perrine's Petition.]

NEW ZEALAND FLAX LILLY.

Curti's Botanical Magazine, Dec. 1st, 1832. *Phormium tenax. Thumb. Diss. Nov. Gen. p.* 94. *First Gen. n.* 24. *Prodr. p.* 325. *Cook. Voy. v.* 2, *p.* 96, *cum. Ic. Thouin in Ann. du Mus. v.* 2, *p.* 228, *et* 474, *t.* 19. *St. Fond. v.* 19, *p.* 401, *t.* 20. *Redoubt. Liliac, t.* 448-449. *Ait. Hort. Kew. ed.* 2, *v.* 2, *p.* 284. *Schult. Syst. Veget. v.* 6, *p.* 621. *Spreng. Syst. Veget. v.* 2, *p.* 76.

Description.—*Root* fleshy, forming a somewhat tuberiform root-stock, creeping beneath the surface of the soil, and sending up many tufts of luxuriantly growing *leaves* from four to eight feet long, and from two to four inches in diameter. They are distichous, vertical, coriaceous, deep green, somewhat glaucous beneath, finely striated, ensiform, the margin and nerve, especially at the backs, are reddish orange; at the base the inner edge has a deep furrow, which sheathes the leaf immediately within it, and upon various parts of the surface a gummy substance flakes off in white spots or scales.

From the centre of these tufts of leaves arises a *scape*, "12 feet high, with 13 branches, of which the lower ones contain about 20 flowers, and the upper ones a less number in gradual diminution as they ascend to the top." These flowers are panicled and secund, ascending or pointing upwards; the *peduncles* and *pedicils* rounded, glabrous, often tinged with purple, and sheathed with scales or bracteæ *margined* with red.

The lower flowers of the branches seem to be very generally abortive and deciduous, breaking off at an apparent joint; the upper ones bear almost ripened capsules, while many of the former are still in full flowers, and these capsules are oblong, tuquetious, brown and wrinkled, attenuated slightly at the base, and surrounded by the withered stamens and floral coverings, acuminated at the extremity, and terminated by the persistent but withered style, somewhat fleshy, three celled, each *cell* bearing numerous, compressed, imbrecated and erect seeds, inserted upon the inner angle of each cell.

In Cook's 1st voyage, Sir Joseph Banks discovered this highly useful plant. Speaking of the productions of New Zealand, he says: "But among all the trees, shrubs and plants of this country, there is not one that produces fruit, unless a berry, which has neither sweetness nor flavor, and which none but the boys took pains to gather, should be honored with that appellation. There is, however, a plant that serves the inhabitants instead of hemp and flax, which excels all that are put to the same purposes in other countries. Of this plant there are two sorts: the leaves of both resemble those of flags, but the flowers are smaller and other clusters are more numerous; in one kind they are yellow, and in the other a deep red.

From the leaves of these plants, with very little preparation, the natives make all their common apparel; and they also manufacture their strings, lines and cordage for every purpose, which are so much stronger than any thing we can make with hemp, that they will not bear a comparison. From the same plant, by another process, they draw long slender fibres, which shine like silk and are as white as snow; of these, which are also surprisingly strong, the finer cloths are composed; while of the leaves, without any other preparation than splitting them into proper breadths, and tying the strips together, they make their fishing nets, some of which are of an enormous size. A plant which with such advantage might be applied to so many useful and important purposes, would certainly be a great acquisition to England, where it would probably thrive with very little trouble, as it seems to be hardy and to affect no particular soil, being found equally in hill and valley, in the driest mould and deepest bog. The bogs, however, it seems rather to prefer, as near such places we found it to be larger than elsewhere."

The seeds brought home by Sir J. B. in 1771, did not succeed; but the New Zealand Flax Lilly was introduced to the Royal Garden at Kew, through the medium of the same enlightened individual in 1789; and thence has been liberally distributed to collections in England and on the continent. Mr. Aiton sent it to the garden of the Museum of Natural History of Paris in 1800; has been cultivated in the open air of many districts, and first produced flowers in the department of *Drôme*, 1812, but it bore no fruit. Messrs. Labillardiere, Faryas de Fond, Desfontaines and Freycinet have devoted much attention to the cultivation and manufacture of this plant. It has even withstood the severe winters of Paris, but in the south of France it has been propagated with considerable success, and survived the winters without the smallest protection. In the departments of the west, particularly in the environs of Cherbourg, it has perfectly succeeded and yielded ripe fruit.

It is readily increased too by dividing the roots. Allen Cunningham, a very intelligent botanist and traveller, gives the following account of the flax lilly. "The Phormium tenax is indigenous to the Islands of New Zealand. On the northermost of the Islands [Equaterward] which has been traversed almost in every direction by Europeans, it is found in greater or less abundance, as well on the immediate coasts in low situations, subject to be overflowed by the tide, as in the inland country, generally, in grounds more or less swampy. Extensively diffused as this valuable plant is over the surface of the Island, it is along its western coast to the southward of the parallel of 35°, and in Cook's Streight, that the greatest quantities have been found, where it is said to grow in fields of inexhaustible extent. The indigenous growth of the Phormium is not limited simply to New Zealand; for it was long ago discovered in a wild state at Norfolk Island, where it forms long tufts along the cliffs, within the influence of the salt spray rising from the heavy surfs which ever and anon lash the iron-bound shores of that small but truly beautiful spot of the Pacific. The preparation of the flax for their own use, or for exchange with Europeans, is effected by the native women; and their method of separating the silky fibre from the long flag-like leaf of the plant, of which it forms the under surface, appears simple enough. Holding the apex of a *recently cut leaf* between their toes, they make a transverse section through the succulent matter at that end with a *shell*, (which they still employ, although they possess every species of iron edge tool) and inserting the shell (said to be of the Genus Ostrea) between that substance and the fibre, readily effect its separation by drawing the shell through the whole length of the leaf. It is to be observed that the separation is always performed by those people when the vegetable *is freshly cut;* as the leaf contains a gum which causes the fibre to adhere more strongly when dry. Nor have the attempts of Europeans to extract the filaments from the leaf *by maceration*, been at all successful; the experiments that have been made at Sydney, showing that the large proportion of the succulent matter, (for so the failure was accounted for) rendered it impossible to effect the separation by decomposition in water, without *materially injuring the strength* of the fibre. Simple as appears this mode of separating the flax from the leaf by a shell in the hands of those savages, still the European has not succeeded in his endeavors to prepare the fibre for himself either by *that* or any other means that have been tried; nor has any instrument or piece of machinery yet been invented to enable *him* to strip off and prepare this valuable filament for the English market. The Port Jackson Traders must still be dependent on the native women and their shells for the cargoes they obtain. The flax thus obtained by the merchants of Sydney, undergoes no heckling, cleaning or other preparation previous to its being shipped for the English market; but it is merely made into bales by being put into a press and screwed. It is manufactured into every species of cordage excepting cables, and Mr. Bigge, the Commissioner of Enquiry to New South Wales, observes, in his Report, pp. 52-53, "that its superiority of strength to the hemp of the Baltic, has been attested both by experiments made at Sydney, and by one that was effected under his own observation in the King's Garden at Deptford."

An experienced captain of a merchant vessel, who had been 35 years at sea, and many years in the trade between Liverpool and Mauritius, spoke much in commendation of the ropes made of the New Zealand flax, having employed them in the ships he had commanded. He had proved its superiority to hemp in ropes upon which there is always a great strain on shipboard; such as stays, braces, tacks, sheets, &c. and such were the strength and elasticity (hence its value for *stays*) and durability of fibre of the New Zealand flax, the ropes could be made of less dimensions, and therefore more convenient to use than those of Baltic hemp required for the same purposes. A *new main sheet*, (which in a cutter is a rope on which there is ever much stress,) after a nine months' voyage, was still good and serviceable, whereas had the rope been made of Baltic hemp it would have been so worn by strain and friction, it would have been necessary to bend another for the return voyage of 7 or 8 weeks' duration.

For many years past, some communication has been kept up by individuals residing at Port Jackson with the natives of New Zealand: but it is only of late that the trade in flax has been found to be a profitable speculation. Of this the merchants of Hobart's town and Launcerton in Van Dieman's Land are now fully aware; and having had their attention turned to its advantages, they are beginning to prosecute it with ardor.

From the experiments of Mon. Labillardiere the relative strength of the New Zealand flax is as follows: the fibres of common flax broke under a weight of $11\frac{3}{4}$; of common hemp $16\frac{3}{4}$, and of the lilly flax 23 7-11—that is, the New Zealand flax is nearly 50 per cent. stronger than common hemp, and fully 100 per cent. stronger than common flax. These *foliaceous fibres* possess also this further advantage over the *cortical fibres* of flax and hemp; that is of the brilliant whiteness which gives them a satinny appearance, so that the clothes made of them need not be bleached by a tedious process, or through those other means by which the quality of flax and hemp is considerably injured. M. de St. Fond asserts that the fibres may be obtained from the leaves by boiling them in soap water. Twenty-five pounds of the split leaves tied in bundles are immersed into a sufficient quantity of water in which three pounds of soap are dissolved. They are all then boiled during five hours until the leaves are deprived of a tenacious gluten or of a gum-resin; and then they are carefully washed in running water. To me it appears this must be an expensive process—yet as the recent accounts from France state that the whole expense of the mode now pursued to obtain these fibres does not exceed six francs the quintal, it seems that French chemistry must have accomplished the desideratum which English mechanics have attempted in vain. Yankee ingenuity, however, has not yet been engaged in the invention of machinery to effect the separation of these foliaceous fibres by simple scraping only. It is true that the machinery will have to be more complicated than the simple apparatus which will suffice for the leaves of the Agaves, of the Bromelias, of the Yuccas, and of all other plants with flat sword-shaped leaves without a midrib. The leaf of the New Zealand flax lilly not only has a midrib extending from base to apex, but also towards the butt the sides of the leaf are folded together, and hence simple machinery cannot be easily applied to scrape the entire leaf. Nevertheless, the simple splitting of the leaves into two divisions through the midrib may overcome this difficulty. The simple process of shell scraping by the natives is undoubtedly the very best of all to preserve both the strength and the color of these foliaceous fibres; and hence the high importance of an American invention to effect the same scraping by labor saving machinery. It is not, however, absolutely essential that machinery shall be discovered to render the propagation of the flax lilly profitable in Florida and in our southern states. Its generic name alone, derived from Phormos, a basket, was given in allusion to one of the uses made of the entire leaves of the plant in its native country. All travellers have spoken with pleasure of the varied uses of the leaves by these rude people for domestic manufactures. Besides their baskets, their mats have excited many encomiums. Some mats are said to be of a peculiarly fine and glossy texture, with deep borders of various devices and different colors worked all round; the style of which, even to a Parisian belle would appear chaste and fashionable. Even the dresses of the natives were made of those leaves, split into 3 or 4 slips, and when dry, interwoven into each other so as to form a kind of stuff between netting and cloth, with all the ends, 8 or 9 inches long, hanging out on the upper side, like shag or thrumb matting. They also made a sort of cloth as coarse as the coarsest canvass, but it was "ten times as strong." Immense fishing nets we have seen, are made by simple tying together slips of the leaves. Of the uses to which the entire leaves and slips of the leaves would be converted to in the United States, some idea may be formed by a reference to the ingenious industry of our country women in the manufactures of hats, bonnets, &c. from the leaves of palms and the stalks of grasses. From strips of the leaves of this flax lilly, hats, bonnets, baskets, &c. would soon be made of much greater beauty, strength and durability than even the celebrated costly hats of Panama; and the price would be reduced proportionately as much as it has been reduced in the price of similar articles now manufactured on the farms and in the families of the New England states, when compared with the sum at which they were sold when imported from other countries. Hence the propagation of this single plant alone on the worst soils of the Southern States, would not only cover them with a dense population of small cultivators, but might also triple that rural population by giving employment to their families in really domestic manufactures. At all events the numerous small cultivators of the south would thus be enabled to furnish the cheapest possible raw materials for the numerous small manufacturers of the north; and would thus create a mutually profitable and harmonious dependence of the great masses of population in both sections of the Union on each other.

The increase of the flax trade with the New Zealanders, may be inferred from the following statistical facts. In 1828, the export of New Zealand flax from Sidney to England was 60 tons, and valued at £2,600 sterling. In 1830, the same exports ascended to 841 tons; and in 1831, to 1062 tons, for the English market alone. That this flax lilly can be profitably propagated throughout all our southern states, may be inferred from the fact, that it is profitably cultivated in the southern departments of France, and from the still more decisive fact, that it has flourished several years in the open air of Charleston, S. C. For my own part, I have not the slightest doubt that it may be spread over all the worst soils of the southern and southwestern states, especially in the pinewoods, magnolia swamps, and other evergreen forests between the Potomac and the Mississippi. Should it not extend farther inland than the live oak, or within the influence of the saline atmosphere of the ocean, it merits to be spread over the whole extent of country heretofore covered with the live oak. At all events, there is every human certainty that the territory of Florida is especially adapted to the flax lilly, and that it might there be extended over millions of acres, as it is in its native New Zealand and Norfolk Island. My convictions of its certain success in Florida, are founded on the descriptions of the climate and vegetation of New Zealand given by all travellers. Although these islands are situated between 34 and and 48° S. L., yet as they are very narrow in proportion to their length, their temperature is more moderate and uniform, and the atmosphere more humid than would be inferred from their latitudes alone. In a voyage to New Zealand in 1814-15, by John Liddiard Nicholas, Esq. and Rev. Samuel Marsden, they say, in speaking of the Bay of Islands, lat. 25° S. "The climate was so salubrious and inviting, that even in the depth of winter no other change was perceptible than a few refreshing showers, which gave mellow and vernal softness to the fields, while no sudden or violent transitions ever disturbed the serenity of the mild atmosphere." Again, on their excursions into the interior of the Northern Island, they remark, "there was one feature of the country which every where struck us with admiration; and that was the fine rich verdure of the landscape wherever we turned our eyes, and which gave us at the same time a high opinion of the genial influence of the climate. In 'Hawkesworth's Voyages,' v. 3, p. 34, it is said, "From the vegetables found here, there is reason to conclude that the winters are milder than those of England; and we found the summer not hotter, though more equally warm. Of musquitoes and sand-flies, a few were found in almost every place where we went ashore." In another place, it is observed that the English vegetables left by Cook on his first voyage, continued to propagate themselves, although many of them were too tender to survive a winter in the open air of England. The character of vegetation also confirms my opinions. Many New Zealand plants are such as are found within the tropics or on their borders. The shores in many parts are beset with mangroves; the interior is covered with arborescent ferns, and in many parts the woods are so overrun with supplejacks, that it is scarcely possible to force one's way among them. Among the trees, were observed two or three kinds of fern like those of the West Indies. At Norfolk Island, where a sort of spruce pine trees are very large and very abundant, cabbage palms, of 10 to 20 feet high, are also a spontaneous growth; and here the flax lilly is still more luxuriant than in New Zealand. In New South Wales they give a decided preference to the flax lilly of Norfolk Island both for quantity and quality.

But in both islands, whether in pine forests or undulating savannahs, whether on the seacoast or in the interior, on hills or in valleys, the flax lilly flourishes in the greatest profusion, as well in the most exposed, as in the most sheltered situations.

Enough, however, I trust, has been said to prove that this flax lilly can be propagated easily, at least throughout all Florida, and probably throughout all our southern and south-western states. As the fields of France already furnish lilly flax enough to afford employment in manufactories to several thousand workmen, it may be anticipated that the forests of Florida will furnish soon flax lilly leaves enough to employ a million of family manufacturers.

HENRY PERRINE.

Washington, D. C., 19th Feb., 1838.

From the Journal of Agriculture.

THE MARRIED AND UNMARRIED.

Some very curious facts on the subject of marriage, as connected with longevity, are stated by Dr. Casper, in a paper of his, lately published at Berlin. It had been long ago vaguely asserted, that bachelors are less long-lived than married men. Hufeland and Deparcieux were of this opinion; and Voltaire observed that there were more suicides among those who had not given hostages to fortune, than among those who had. Odier, however, was the first who set on foot the inquiry with exactitude, and he found (Bibl. Britannique, 1814) that, in the case of females, the mean duration of life for the married women of 25, was about 36 years; while for the unmarried it was about 30½. At 30 there was a difference of four years in favor of the married; and at 35 two years, and so on. It may be said, perhaps, that married females ought to be considered as picked lives; but, as Dr. Casper observes, this is far from being generally the case, especially in the middle and upper classes of society; it is chiefly among the lower orders, where a livelihood is procured by labor, that importance is attached to the bodily health and vigor of the female. With regard to men, we gather from Deparcieux's and the Amsterdam tables, that the mortality of those from 30 to 45 years of age, is 27 per cent. for the unmarried, while it is but 18 for the married; and that for 41 bachelors who attain the age of 40, there are 78 married men. The difference becomes still more striking as age advances; at the age of 60 there are but 22 unmarried men alive for 48 married; at 70, 11 bachelors for 27 married men; and at 80, for the three bachelors who may chance to be alive, there are 9 benedicts. The same proportion very near holds good with respect to the female sex: 72 married women, for example, attain the age of 45, while only 52 unmarried reach the same term of life. Mr. Casper, in conclusion, considers the point as now incontestably settled, that, in both sexes, marriage is conducive to longevity.

THE BLENDING OF WINE, SILK AND DAIRY ESTABLISHMENTS.

To the Editor of the Farmers' Register.

Brinkleyville, Halifax Co., N. C.,
March 16, 1838.

Having reason to believe it not contrary to the wishes of the writer, I send you, and offer for publication, a letter I received by our last weekly mail from N. Herbemont, Esq. of Columbia, S. Carolina; a gentleman, long known by the intelligent American public, as a zealous promoter, by his pen and example, of agriculture in general, as well as of the wine culture in particular. I beg leave, however, to accompany the publicity of this letter with a passing remark or two on some of the topics noticed therein.

As to honoring my name by conferring it on the kind of grape I have been instrumental in bringing into notice, I consider the doing of this rather premature, to say the least of it. The peculiar excellencies of this grape may be merely *local.* In our locality, it has amply proved itself to be as I have described. And it is the opinion of all intelligent visitors to my vineyard, who have seen it, partaken of its fruit, and judged of the wines therefrom, that it will prove a first rate kind for our country in general. But this remains to be tested by experience, the only infallible criterion in such matters. Apart from its locality, it may not be found worthy to retain a name at all.

And the above-named criterion will be had ere long; for I have lately sent vines and cuttings thereof into various sections of our country, as New England, and the states of New York, Alabama, South Carolina, and Ohio. N. Longworth, Esq. of Cincinnati, now noted as one of the greatest *vignerons* of our country, assured me in a late letter, that he would test the qualities of the Halifax as a wine grape in 18 months.

And if permitted to compare facetiously little matters with great ones, I know not but if I assent to Mr. Herbemont's proposition, I might do a like injustice as that done by Americus Vespucius to Columbus. As named, in answer to late interrogatories propounded to me in a letter from a highly esteemed correspondent, A. B. Spooner, Esq. this vine first attracted my attention in a vineyard of a Mr. Smith of this county; or, in an enclosure of his I call *nature's vineyard*, because formed by leaving vines in woods while clearing, and the trees round which they had entwined themselves. But if still thought, by those competent to judge, that the successful *cultivator* ought rather to be entitled to have the honor of the name, than the original *discoverer*, I should, as I have said to Mr. Herbemont, in answer to his suggestion, prefer retaining the *Halifax*, and have the grape called *Weller's Halifax*, if found, in due time, worthy of a *name*, or *change* of name.

On reading Mr. Herbemont's letter, I was highly gratified to find that, in publicly avoiding an opinion that the grape and silk culture might, with the greatest advantage, be conducted by the same hands and in the same establishment, I was but reiterating the sentiments of so good a judge on such subjects.

The peculiar advantages of blending a dairy establishment with those of the vine and silk culture, never occurred to my mind till suggested by Mr. Herbemont's letter. But, as he states, it must be evident to every competent judge on the subject, that *negatively*, the business of the dairy establishment would not interrupt the business of the others, but would *positively* conduce, by its healthy diet and profit, to the advantage of all concerned. But here, I confess that the advantages of stock or cattle for enriching the ground, preparatory to the culture thereon of vines or the mulberry, are not, I consider, so great as some would suppose. According to my 'American System of Vine Culture,' manures (so far as necessary) from the place of *wood-pile*, from low-grounds and sides of ditches, and from the woods, are competent, in general, to ensure complete success. That is, I conceive other than animal manure is better for both vine and mulberry culture; and that the resources on almost every plantation of chip manure, swamp or ditch bank dirt, rotten logs from the woods, surface earth from the same, and, after vines or trees have sufficiently advanced, leaves, pine straw, or green pine boughs strewed thickly underneath, answer all purposes of sustaining the bearing and flourishing. But suppose, as Mr. H. states, the poorer lands of a plantation, (with the above help,) will answer for vine and silk culture, independent of help from the kine of the dairy, yet the richer lands need the latter help to sustain the stock in return, by clover and grasses, and roots, as well as to afford bread-stuff for all.

And here I am tempted to branch off into a long digression on the great advantages of clover, other grasses, and root culture, to support the stock, as well as for other purposes; and advantages of stock, on the other hand, for keeping up and enriching lands preparatory to the above objects of culture; but aware that time and space forbid, I beg leave to add, in conclusion, a few remarks only on the dairy, and means of sustaining one to the greatest advantage in our southern country. And first, a general error is to be avoided; that is, of suffering cattle to run at large, instead of soiling or pasturing, as is done in England, whence come the improved breeds of cattle, and as is done in Goshen, the famous place for butter in New York state. Another error connected with the above, and unknown, I believe, in the above-named places, is that of allowing the calves to suck the milch cows. I say, connected with the above, for I cannot conceive any reason for the practice, except that of inducing the dams, wandering in the woods in the day time, to return to their calves at night. Now field-pasturing avoids the troublesome business of *whipping* calves away from their dams before a moiety of the milk can be obtained, and absurd notion that cows cannot be induced to "let down their milk" before the calves first suck. But here, to avoid these errors, I confess requires preparatory steps—steps almost as necessary as to have a mulberry orchard before you can make silk. The clover, or other grass culture, should be first attended to, in order to sustain both calves and cows; and it is also desirable to enter upon ruta-baga culture, not to name other esculents. And I candidly confess, that in our southern clime, connected with sandy soil, are peculiar difficulties to overcome, in order to successful clover culture; which culture may be called the key to all after permanent improvement and sustaining of lands. But such difficulties (as I, in common with others, have proved) are not insurmountable. I have found that even on most light and sandy soils, by first manuring well, if necessary, (leached ashes highly important,) and sowing clover with wheat early in the fall, after taking off a forward crop of corn, or cutting up some after grains are glazed, good clover lots may be had, and a system of improvement thereby kept up, as well as the dairy. The object in sowing clover in the fall on light sandy soils, is to have the clover grown in the fall beyond danger of being winter-killed, and to have it so well rooted in the spring, as to sustain safely the summer droughts, so heating to sandy soils. For greater security of the crop, by pushing the growth, I sow a mixture of plaster of Paris and leached ashes—say, one bushel of the former to three of the latter per acre, after the clover is in third leaf. An old field of broom sedge enclosed, will answer for a standing pasture till the clover is in blossom, or fit to pasture or cut for soiling.

The ruta-baga I have found a sure and very abundant crop, by manuring plentifully in the drill where necessary, and sowing, or rather planting, about or before the middle of July. No better vegetable, not only for family use in general, but for fattening cattle and making cows give abundance of milk in winter.

By the aforesaid plan of managing cows and calves, I have had both to do far better than those of my neighbors, by the old one in practise here.

From *two* cows, I have had produced more milk and butter than some around me from *two dozen*. It is true, at first, I had to use personal vigilance, as well as example, to prevent ignorant hirelings from bringing to pass, by negligence, their own *prophecies* of cows going *dry*, and calves *starving*, under the *new* plan. Had to supervise the milking process, and teach the calves by insertion of a finger in their mouths, under the milk at first, to drink (their mother's milk for two or three weeks, afterwards corn meal gruel); but this done, even prejudiced ignorance itself had to confess my plan the best. As I am for abridging labor in all feasible cases (my vineyards afford an example, under the "American System," of pruning only in summer, and after prevented being bushy vines not curtailed in length, and no necessary work on plantation by common quota of hands much interrupted,) shall I suggest a method to save the hard work of a hand, where the dairy establishment is considerable; which saving may be considered especially important, where the three sorts of business may be conducted in the same establishment.

The method I would propose, is that of putting the labor of churning upon *dogs;* and that, too, without abridging the plantation usefulness of these animals. Various expedients were once resorted to in the Goshen district of *butter* celebrity, as that of a rolling or log machine drawn by a horse. But finally, they fixed upon a process that combined simplicity and economy. A machine, costing a mere trifle, consisting in part of boards or planks, so put together that the surface resembled a large cart wheel, and this, in the position of an inclined plain, was the receptacle for the dog; so placed thereon that he must *step* and *turn* the wheel, or *choke;* (the former *alternative* he always *chooses.*) The turning of the wheel moved some simple machinery above, connected with the churn within doors.

In fine, Mr. Editor, to bring this communication to a close (now extended to a length unthought of at first on my part,) I would most respectfully suggest, that at this period, when premiums are offered by a wise munificence of some legislative bodies of our country, to encourage silk culture, as well as other agricultural pursuits, that a handsome reward be held out to individuals of *capital*, as well as of spirit and enterprise, to exhibit practically the benign bearing or effects of combining the vine and silk culture, and dairy business, in one large or considerable establishment. And may I here be permitted to express a wish, that the legislative bodies of the Old Dominion and Carolinas would *snatch* the *laurel* from their sister states, in being first to call forth this enterprise by their timely munificence.

SIDNEY WELLER.

A remark or two I wish to add, or wish to be added, if deemed best, by way of notes or P. S.

The entire *Goshen* system alluded to, of managing cows and calves, is to let the calves intended for *veal* suck all the milk of their dams, for three or four weeks, and then butcher them. But those intended for raising, as before stated, are immediately separated from the cows, and learned to drink.

One advantage, not to be overlooked, of combining silk and vine culture, is the healthiness of grape fruit; or that all employed in the blended establishments may have, in the most sickly season of the year, free access to a diet, that not only counteracts or anticipates disease, but excellent, if from any cause disease occurs. Invalids, by advice of physicians in parts of Europe, with the happiest effect, confine themselves for months to a grape diet; making it answer for both *meat* and *drink*.

That a grape diet of the right kind (I mean *ripe* berries of select varieties for American vineyards, not *green* ones, or those *snatched* from the birds and opossums in the woods,) I know is excellent, from the experience of my own family and neighborhood. We are in general never more healthy than in grape culture; and none of my household and hands, of late years, have been *stinted*, but have partaken abundantly of grapes about two months.

I have known persons, in cases of severe and continued sickness, to relish good grapes when they could eat nothing else, and there was reason to believe their lives were thereby saved.

The Isabella grape is particularly recommended in cases of bilious fever, and from trial, I believe the Scuppernong, and my Halifax, are not behind it in point of healthiness. But it may be objected, that grapes for common diet must be very *costly*. Not so. If vineyards have a proper selection and management, there are few things else cultivated will produce more human food from the same space of ground.

Mr. Broddie's Scuppernong vineyard, (I have noticed before,) of half an acre and fourteen vines, yields 20 barrels of wine annually; and all his neighbors partake abundantly, by visitations and carrying away baskets of the fruit.

Of the yield of my vines I intend to speak, in a separate communication, to sustain the same position. Suffice it to say here, that owing to the fatality of the past season to grapes predisposed to rot, my chief dependence for fruit and wine was on the Scuppernong and Halifax. Avoiding particulars here, I will say, that from a small space of ground, canopied with these vines, after bushels being taken away by visitors (often 20 a day) and sold to those sending from a distance, I made upwards of 100 gallons of wine. I have noticed, after a visitation of 20 or more persons to a few vines of the above-named sorts, no perceptible alteration of appearance, but the same thick *purple* or dark *cloud* of fruit remaining. I cannot forbear here stating a particular or so in regard to the yield of these vines. One Scuppernong, a square of ten feet of canopy being measured, produced at the rate of 870 bushels per acre, (a bushel of Scuppernong grapes makes nearly four gallons of wine when well pressed,) and that, too, after giving its share of fruit to visitants. One Halifax, at the 3rd year's cultivation, yielded a half bushel of grapes; another at the 5th year, a bushel; and another grafted one at the 4th year's growth, one and a half bushels. (One bushel of Halifax berries in racemes, makes more than three gallons of wine; if pulled from racemes, would make as much as Scuppernong, I presume.) And considering the space occupied by the foregoing vines, I believe the yield full as great for the ground, as that of the Scuppernong above-named.

By the facts of warning against disappointment of success in clover culture, in our southern *sandy soils*, I would not be understood to discourage sowing clover in the *spring*, in ordinary southern soils. The state of North Carolina is now going *ahead* in clover culture in many sections of the country, through the light thrown thereon by our agricultural periodicals. Last summer, I saw as fine a field of clover as ever I beheld, on the plantation of Mr. Massenburgh, a very intelligent, enterprising farmer, near Louisburgh, N. C.; and if I recollect his information, he was not even indebted to plaster of Paris for his success. My excellent and intelligent neighbor, Mr. William Thorne, has successfully cultivated clover for several years; but the first year he commenced would have been a total failure, had he not resorted to a dressing of plaster. A long dry spell came on in the summer, after he had sowed a bushel of clover seed in the spring, and his young clover was apparently *killed;* but the plaster revived it, and a very fine crop was the consequence of its resuscitation.

S. WELLER.

ON GRAPE AND SILK CULTURE.

To Sidney Weller, Esq.

Columbia, S. C., March 8, 1838.

Dear Sir—I have, yesterday, received your obliging letter of the 26th ult., and also three small cuttings of your grape vine, which you call "Halifax," and which I propose to call "Weller," after you. It is perfectly fair to name plants, or fruit of great value, by the name of the person who introduces them, not only into notice, but takes great pains to extend their culture. By this means, benefactors of mankind have their names honorably transmitted to posterity.

I am glad that your opinion coincides with mine, as relates to the culture of the vine and silk at the same time by the same person. There are, perhaps, no two articles of culture, the prosecution of which interferes as little with each other; for at the very time that the silk worms require all the attention and care necessary to their welfare, the vineyard should not be entered, and indeed with the proper degree of industry required in the culture of any thing, the vines must be, during that short period, in such a state as not to require any thing being done to them. Besides this coincidence, as to time, much is to be done in the vineyard that requires more attention than strength; so that the same persons who are adequate to the cares of the silk-worms, are also sufficient to do much that is required in the vineyard. What sources of wealth and comforts will, I hope, be some day produced, by the joint culture of these two valuable articles. They are the more valuable that they require no capital of any amount to be established, provided there are larger proprietors in the neighborhood. These would always be ready and willing to purchase of their poorer neighbors, their cocoons and the grapes of their own raisings; and these would gradually learn the arts of preparing the silk for market, and of making wine, *secundum artem*, as their profit would, in time, afford them the means of forming suitable establishments for these purposes. Another great advantage attending these cultures, so as to make them suitable for the poorer class of farmers as well as the richer ones, is that both these articles of culture, require land only of inferior quality for their fullest success. It is certainly a fact that the wines produced on poor light lands, are of a superior quality to those produced on richer clay lands. I have no experience in the culture of silk sufficient to enable me to speak of my own knowledge; but the books I have read on the subject, state the fact clearly and distinctly, that the mulberry leaves produced on poor land produce finer and superior silk. Here are, then, two objects as valuable, if not more so, than any other yet cultivated in this country, which offer the incalculable advantage of leaving the richer lands for other necessary articles of culture. I regret much that I am too old to hope to see the immense benefits, which our country will derive from the culture of silk and the vine. (We are never at a loss for finding a good reason for wishing to live long.) There is, I think, another object of rural economy that would harmonize well with the two mentioned above, and would tend to the great comfort of the cultivator, and that is the dairy. It appears to me that a dairy establishment would scarcely interfere at all, either with the raising of silk or of wine, and it would undoubtedly add much to the convenience and comforts, not only of the cultivators, but also of all the country around.

I had no idea at all of writing on these subjects, when I began to write; but my pen would go on, and I gave it its way. I merely intended to say, that I had received the three grape cuttings you were so obliging as to send me; that I gave one of them to one of my neighbors, who is also a zealous cultivator of the vine, and that I grafted the other two. I hope the box you are sending, will also arrive safe and in due season.

I am respectfully, sir, your obd't. serv't.

N. HERBEMONT.

MR. WELLER'S WINE.

We lately received from Mr. Weller, two bottles of wine, made by him from the native grapes referred to in the foregoing and a previous communication. One was labelled "Scuppernong," and the other, "Halifax Grape;" and both were of the pure juice of these grapes, except for the addition of sugar before fermentation. The two wines were tasted and drunk, not at the same time, but at times a week apart; and therefore we may have been mistaken in supposing that there was no difference in the flavor; nor was there any apparent difference in any other respect. From this close resemblance, it would seem that it is the process used, and not any peculiar quality of either grape, which gives character to this wine. Though fond of good wine, we make not the *slightest* pretension to the character of a *connoisseur*; and therefore our opinion on this subject may be worth very little. But according to that opinion, this wine is the most delicious drink that we have ever enjoyed. It is altogether unlike any known imported wine, except champagne, which it resembles in flavor, color, and transparency, but not in sparkling, as these are "still" wines. But what is most remarkable and admirable in them, is the preservation, in a high degree, of the sweet and rich scent of ripe muscadine grapes. Mr. Weller's wine has more of saccharine flavor, and less alcohol, than would please regular drinkers. It is altogether different, in color and flavor, (and often too in ingredients,) from what is sold under the name of Scuppernong wine; and it would be judged of very erroneously, if considered as merely a superior kind of the liquor generally sold as Scuppernong, or other common home-made wine, whether the latter be really principally a product of the grape, or merely a factitious compound.

REMARKS ON SOME PARTS OF MR. GARNETT'S ADDRESS.

Communicated for publication in the Farmers' Register.

Columbia, S. C., Feb. 17th, 1838.

J. M. Garnett, Esq.

My dear Sir—I have read with much pleasure, approbation and benefit, your "Address to the Agricultural Society of Fredericksburg," published in the last "Farmers' Register," and take advantage of a very cold morning, when I cannot go out, to make a few observations on some part of it. (I call this a cold morning; my thermometer was yesterday at 66° and it is now 32°, 9 o'clock A. M.; and now, when I finished writing, 3 P. M., it is 34°, although the sun has been shining ever since morning.

The account of your experiments on corn are very interesting, and it is very desirable that farmers and planters generally would do the same. Besides the advantages expected from experiment, such as the obtaining better and more productive varieties of the articles experimented upon, there is another great one, which is, that it has a tendency of producing a habit of careful culture and of observation; for the experimentor naturally wishes to succeed in what he undertakes, and will pay, in the conducting of his experiments, more care and attention than he would do in the ordinary course of his pursuits. He may do this unconsciously; and even in this he is benefited by the habits acquired by it. Agriculture being the real business of this country, particularly of the southern states, every effort should be made that has a tendency to produce a state as nearly approaching perfection as is practicable, by every means in our power. The aim of a shoemaker should be to become as great at his trade as he can; that of a lawyer to gain, by fair and honest means, as many causes for his clients as he can, that he may have an opportunity of reaching the first rank in his profession, and finally, to be at the very head of it. It is so with every pursuit, and we ought to keep the old adage in remembrance, "that what is worth doing at all, is worth being done well." Now, sir, as without agriculture, we can have nothing to eat, except what nature spontaneously affords, nor any clothing to keep us warm such cold weather as this, it follows that, if every man is not an agricultor, he is interested in the success of agriculture, as much so as he who pursues it as his profession. The natural and fair conclusion of this indisputable mode of reasoning is, that every individual in the country is interested in having agriculture carried up to as high a degree of perfection as it is possible. This renders the thoughtless folly of our legislatures in refusing any and every sort of encouragement and assistance to so useful and essentially beneficial a profession as agriculture, unaccountable, and I hesitate not to say, criminal. We may, it is true, find some excuse for such members of our legislatures as are not agriculturists, and that is that they do not know the wants of those that are, nor in what manner due encouragement and assistance are to be afforded. This excuse, however, does not reach the agriculturists themselves, who have much in their power to promote the great interest of the country and neglect doing so. The principle of "*laissez-nous faire*," which is by some insisted upon, does not apply here to its full extent, because, before we can carry on any business properly, there must be capital and stock in trade provided, and the doctrine of "*laissez-nous faire*" (let us alone) will not go far in procuring these; for they are chiefly knowledge promoted by a judicious application of pecuniary means and judicial enactments. The elements of agriculture should be taught in every school, and a professorship established in every college, that this most essential science in this country should be understood in some degree by every person in it; for there is no useless knowledge, and the professional man and mechanic who reside in cities can be but benefited by any extent of knowledge in a business like this, although it does not apply directly or immediately to the objects of their pursuits. This brings me to notice this most shameful fact for the United States, a country which is able to furnish bread to a great portion of the civilized world, that they have received, within a year or two, grain from Europe to the enormous amount of $5,333,962, as stated by you in your address. But, sir, you may not be aware that there is a considerable and shameful great addition to the amount of agricultural product imported from Europe into this country, to be added to your statement: That is, that a considerable quantity of hay has been for a couple of years imported to Charleston, not merely from the northern States, but from Europe. I believe, that notwithstanding this strange article of importation, there are few countries in the world better calculated for the production of the grasses and the making of hay, than South Carolina, and yet we import it and pay for it sometimes as high as $2 50, or even $3 per hundred weight. Wealthy as this state may be in its other agricultural productions, can the difficulties of the present times be a matter of surprise? It is only to be wondered at, that we have not suffered much more. It will probably be thought that I am of a querulous disposition, which may be true; at any rate, I hope you will not accuse me of this yourself, for if you did, I would say you have awakened the fit in me. Our excuse, is a very natural and aged one, that we have for many years made all the exertions in our power to produce a better state of things, and that, besides, it belongs to our time of life to bear such things somewhat impatiently. This being my acknowldeged infirmity, I beg my friends to put up with it as well as they can, in consideration of the undoubted good motives that prompts it.

There is, however, in the ways of the world, as relates to agricultural affairs, enough to vex the patience of even younger men. The very great liberality of the Editor of the Farmer's Register, in lately proposing to render his most invaluable publication, considerably cheaper than it is now, by additional subscribers, induced me, during the late session of our legislature, to make as much exertion as my feeble health would permit, and I had full expectation to succeed to some extent. Another subject, however, had taken hold of our representatives, and nothing could be noticed by them, but a subject upon which they could not legislate, and which ninety-nine hundredths of them did not at all understand, viz.: the currency. The consequence was a total disappointment; and nothing to which my effort tended was effected. I also endeavored to procure some aid of the marl districts of this state, from the members from that part of the country; but, as I could not mingle *currency* and *banks*, or *no banks* and the *subtreasury scheme*, I could not draw the least attention on the subject I wished to promote. I see, by a short communication, near the end of the last number of the Farmers' Register, by the Honorable F. H. Elmore, who is truly deserving of the epithet prefixed to the names of the members of congress, and a great friend to agriculture, that he sent a small specimen of marl to the editor, whose observations and well deserved reproofs on the inattention paid by the agriculturists of the lower part of the state to so valuable a resource at their hand, and which they totally neglect, and that his (the editor's) "request, advice, and instruction have not served to induce a single cultivator to marl even so much as an acre of land." "Truly," (continues he) "we have but small encouragement to persevere in offering to them advice and instruction."

Is it not surprising, my dear sir, how difficult it is to introduce any thing new, or improvements in our habitual practices? and this is more especially true in agriculture. It is not that they doubt the efficacy of the use of marl and other carbonates of lime, so much as that it is a deviation from their usual practice; for none of those to whom I have mentioned the great benefit derived elsewhere from its use, have shown any sign of disbelief, and the only objection that I could ever observe, was the necessity of making some exertion in a way different from their usual course, and also the expense attending it; although this last would not have been a material objection, if it could have been effected by merely paying the money.

Although I agree very well, generally, with you in your views of agricultural things and policy, yet there is one subject on which I cannot go so far as you do. You seem inclined to the opinion that, in the cultivation of corn, the cutting of the roots by the plough and other instruments is benficial to its growth. I admit with you that generally the benefit obtained from the ploughing out-does the disadvantage of cutting the roots; but I think that the corn does well, not *in consequence* of the roots being cut; but in spite of this mutilation. The land being in good heart, and stirred deep, has undoubtedly, the state of weather being favorable to the strength, caused many small roots with their spongioles to push from the ends of the mutilated old roots, and by this the crop does not seem to suffer. I have often seen, after such a ploughing, the weather being unfavorable, the corn to be much injured, by what is usually called "firing," which I attributed, perhaps erroneously, to the roots having been cut when the corn was not able to produce a fresh supply of them. The producing of these new roots with their spongioles is, however, in every case, an effort of the plant, which might probably be otherwise applied to other useful purposes to the plant's welfare. It is true we have no experiments that I know of tending directly to prove or disprove clearly and distinctly my opinion; but I think the experiment of Mr. James Camak, of Georgia, goes far to prove on one side of the question, that the roots of the corn never being cut in the course of its growth, is not an obstacle to the producing of a large crop. You know that his experiment was, first to plough his ground well and deep, plant his corn, and when it was only a few inches higher, to give it a slight hoeing, and then cover the whole field with leaves from the woods, three, four or five inches thick, and then let the field alone without any further work at all, till it was fit to be gathered. By this method, he obtained more than double the quantity of corn usually produced by the land. Now, I was formerly personally well acquainted with Mr. Camak, and know him fully deserving of confidence in his assertions, and incapable of willfully asserting that which was not most strictly true. His plan of cultivating corn is only practicable in new settled countries, where the abundance of forests affords a full supply of leaves, of which a very great quantity is required to cover a field. The cultivators in the old settled states, have put it out of their power, by their unprovidence in most wastefully destroying their timber; but it seems to me that this experiment favors my opinion very strongly.

There are many other parts of your most useful and interesting address, on which I intended making a few observations; but as these would have been of little worth, and that you must be tired of reading this long epistle, I shall close it here by assuring you that I am, most respectfully,

Dear sir, your obd't. serv't.

N. Herbemont.

Extract from the London Farmers' Magazine.

JERUSALEM ARTICHOKES.

I was determined to prove whether or not they could be cultivated to greater advantage than the potatoe, as *food for cattle.* One sack was consumed by a young calf at hand; it eat them with avidity, and improved on them. I took the other two sacks, and planted them in the midst of a five acre piece of potatoes. I set them without cutting,—measuring correctly an eighth part of an acre; the produce was in proportion to 630 bushels per acre,—the potatoes 327 bushels. The following year, the memorable one of 1826, I planted half an acre on a piece of thin gravel, old tillage land, in its regular course of preparation for a vegetable crop after wheat; they maintained their verdure through that extraordinary dry summer, and produced 150 bushels; but the potatoes by the side of them were completely set fast; they never formed a bulb. The year following, I set an acre on part of the same kind of soil, but of better quality; it produced 570 bushels, *without any dung.* A half acre on the same land, with the usual quantity of dung for turnips, produced 290 bushels (a bad compensation for eight loads of excellent dung.) This present season, an acre on the same land (part of my turnip-fallows) produced 576 bushels, but the wet state of the soil when taken up, and being a vegetable of uneven surface, which causes the soil to adhere to it more than to a potatoe, renders it difficult to come at the exact quantity. From an experiment I made of washing a sack, I can safely assert, I have 530 bushels of clean roots; whilst the vegetables on our flat gravels do not equal this by full 50 per cent. in value, except the potatoe, which produced 308 bushels on the same soil. I never could raise more in favorable seasons.

"The cultivation of the artichoke is the same as of the potatoe, except that it requires to be set early—not later than March; if laid above ground all winter, it is proof against the severest frost. When once cleaned, no weed can live in its dense shade; horses, beasts, and sheep consume it with avidity; pigs prefer a potatoe to it in its raw state, but prefer the artichoke when boiled or steamed. It attracts the game in a most extraordinary way; they resort to its shade in autumn; it forms one of the finest covers in nature. We are so fortunate as to have but little game in our lordships; I do not recollect ever having seen even a Swedish turnip bitten by a hare or rabbit, notwithstanding they will consume the artichokes left by the men in securing them.

If potatoes can be profitably cultivated as food for cattle, compared with Swedish turnips, mangelwurtzel, the sugar beet, &c. (which I much doubt,) the artichoke is vastly superior to them. The expense of culture is no more; it is not liable to be injured by frost; can be taken up at pleasure; it produces at least 30 per cent. more, and on poor land full 50 per cent., *is far more nutritious*, and leaves the land perfectly clean. The only objection that can be urged against their cultivation for cattle in competition with potatoes, is, that they require more care in taking them up. The frost not acting upon them so as to destroy vegetation, what are missed will, of course, grow among the succeeding crop, but I have found very little inconvenience in this respect."

From the British Farmer's Magazine.

BENEFICIAL EFFECTS OF BONE MANURE.

The very interesting details of the efficacy of the bones of animals when employed as manure, as set forth in Mr. Johnson's paper in your last number, induces me to trouble you with a short relation of their lasting effects on a small farm with which I was intimately connected.

On the northern slope of the river Colne, which separates the counties of Buckinghamshire and Middlesex, and within a mile or two of the town of Rickmersworth, lies a little farm which is famed for its great fertility. The lands on each side of this little Goshen were of the same quality, had the same south-east aspect, and were in every respect similar to the little farm itself; but the crops on this were invariably and constantly better than on the neighboring fields. It was an appendage to a much larger farm at some several miles' distance, at which the owner resided, and at which his numerous flocks and herds were kept; except a score or two of store sheep, which were occasionally sent to have the run of the leys and stubbles of the small farm.

The system of cropping was the same on this as on the surrounding farms, namely, the five-course:—fallow for turnips—barley and seeds—clover mowed twice—wheat—oats. But whatever were the crops, they were always superior, and created envious feelings among the surrounding farmers. I, as one of these, set my head to work, to discover what local circumstance could possibly render this spot more productive than the lands adjoining. It was, like all other land sloping to the east, of a deeper staple, and a finer loam, than the more abrupt and gravelly or rocky slopes which faced the westward. For this is a geological fact, and observable over all the continents of Europe, Africa, Asia, and America, that the western sides of all their hills are more precipitous than the eastern; and the western shores of these continents are more abrupt and broken than the eastern.

This has been accounted for by the supposition that the grand current of the Noachian deluge flowed from the westward, washing bare the western sides of hills and continents, and depositing the finer earths, thus removed, on the eastern slopes, as we find them at the present day.

That the surface of the little farm we are noticing was of this diluvial deposit, was very evident; but not more so than the other lands to the south and north of it; and yet, as already stated, it was of superior fertility.

In questioning an aged laborer who had long been employed on and about the said farm, as to how long it had had the character of being eminently productive? he answered, ever since it was farmed by the grandfather of the present owner, who, he said, was a very curious man in his farming; for he not only chalked all his land, but limed it frequently for turnips. And besides laying on it all the yard dung, he used to buy all other kinds of dress he could muster from the skinners and curriers of the neighboring town. But, above all, he used to collect bones from all the dog kennels around, had them broken into small pieces with sledge hammers, and spread them upon, and ploughed them into, the land, for any crop he wished to raise; and this he continued to do as long as he lived.

At his death this dressing with bones was given up; his son thinking them of no great value; and the larger farm at which he resided engrossing his chief attention, the small farm was but seldom visited, notwithstanding it still continued to maintain its old character.

The operations of the grandfather in improving his little farm, must have been carried on about 1765, and were almost forgotten till about fifteen years ago, when a Lincolnshire bailiff was hired to superintend the business of a large farm in the immediate neighborhood. This stranger began his improvements by applying crushed bones upon his turnip fallows, and upon some of his upland meadows. And when this was observed by the old laborer before alluded to, he declared that it reminded him of what he had seen done when he was a boy, by his old master on the little farm.

The discussions which took place among the farmers, as to the effects and value of bone manure, as recommended by the Lincolnshire bailiff, and the reports which appeared weekly in "The Farmer's Journal," produced a conviction in the minds of every one acquainted with the history of the little farm, that its extra fertility arose entirely from the great quantity of bones which had been imbedded in it so many years before. And it was strong proof of what was asserted by the bailiff, that their effect as manure would last for forty years.

The above account is a corroboration of what now appears to be a very general opinion respecting the use of bones as a powerful and lasting manure; and in this instance, the imperfect manner in which the bones were broken, has caused them to act more permanently than if they had been crushed into dust.

VERITAS.

EXTRACTS FROM THE REPORT ON THE AGRICULTURE OF ESSEX, MASS., 1837.

By the Rev. Henry Colman.

Essex county lies at the north-eastern part of Massachusetts; and is bounded on the northwest by New Hampshire; on the east and northeast by the Atlantic Ocean; and southeast by Massachusetts Bay; and on the southwest by the county of Middlesex. It embraces in extent 360 square miles. Its population in 1830 was 82,887; its present population 93,689; being about 260 inhabitants to a square mile. It contains twenty-six towns. It is intersected through its whole width by the river Merrimack, which empties into Massachusetts Bay at Newburyport; and the rivers Shawsheen and Agawam or Ipswich. Parker and Saugus rivers are likewise found, but are inconsiderable in length and magnitude.

The general surface of the county is uneven; but there are no hills of great elevation, and few, which may not be cultivated to their summits. The county, for its whole length on the eastern side, is washed by the Atlantic Ocean. Cape Cod, its eastern extremity, projects into the sea, a distance of sixteen miles; and the coast is lined with a rocky shore or extensive beaches; and pierced by innumerable inlets and creeks, on which are extensive tracts of salt alluvial meadow. The county abounds likewise in tracts of a greater or less extent of fresh meadow or peat-bog. A considerable amount of this land has been drained; and by the application of sand, gravel or loam to its surface, has been converted into profitable mowing. Much of this same description of land remains to be redeemed; and will fully compensate for the expenditure, which this improvement may require. There are considerable tracts on the Agawam river, the waters of which are forced back by the mill-dams thrown across it near its mouth, which must be regarded as irreclaimable while those obstructions remain.

The climate of Essex county is affected by its maritime situation. The proportion of snow which falls in the course of the year is considerably less than falls in the interior and western parts of the state; the proportion of moisture in the form of vapor, snow, and rain, is greater. The degree of cold is sometimes as intense, but not as long continued. The spring is in advance of the interior of the state generally, from a week to a fortnight; and the frosts, excepting in some particular localities, are not so early, nor severe. For healthiness, as far as this may be determined by the tables of longevity, this county may be safely compared with any part of the known world.

The whole number of acres in Essex county according to the reports of the valuation committee in 1831, is as follows:

	Acres.
Tillage,	14,113
English and Upland mowing,	31,947
Fresh meadow	15,471
Salt marsh,	14,139
Pasturage,	100,309
Wood,	22,058
Unimproved,	34,281
Unimprovable,	10,417
Owned by towns and other proprietors,	3,604
In roads,	6,606
Covered with water,	17,176
Total,	270,121

The soil of Essex county is of a primitive formation; and of various characters. There is a locality of limestone mentioned by the geological surveyor in Newbury and Bradford; but it is believed of small extent. There is little purely sandy land excepting on the sea-shore. There are extensive tracts of peat-bog. The soil on the sea-shore among the projecting cliffs and ledges, on the peninsulas and islands on the coast, with the exception of Plum Island, which is almost unmixed sand, is a deep rich loam, highly productive in grass, corn, oats, and potatoes. On the main eastern road from Salem to the extreme line of the country, there prevails generally a gravelly loam from six inches to a foot in depth; not difficult to be worked; and productive under good cultivation. The lands bordering on the Merrimack are much broken; but the hills are generally rounded, of not difficult ascent, and composed of a rich dark clayey loam. They ordinarily produce good crops of wheat, barley, corn, oats, and potatoes. This variety of soil embraces an extent of three or four miles from the river on the south side. On the west side the land is much more charged with sand, and is not so fertile. With the exception of a considerable tract in Haverhill and an island of fifty acres lying below the bridge in Haverhill, there is no fresh alluvial meadow on the river. The towns in the interior of the county are of various character, in some places presenting long strips and high eminences of rich clayey and gravelly loam; and in other parts a broken, thin, hungry, and stony soil, the cultivation of which is difficult and unproductive. The primitive forests have been long since removed; but there are extensive tracts of wood in different parts of the country. The maritime parts are principally supplied with fuel by importations of wood from Maine, or coal from Pennsylvania. The interior have a supply from their own wood lots; or their peat-bogs, the value of which is becoming more highly appreciated.

The soil has in parts of the country become exhausted; and in no part of it can it be advantageously cultivated without manure. The stony and rocky character of the soil is in some places an impediment to cultivation; but a large proportion of the land in the county is already under partial improvement or susceptible at present prices of labor, while present prices of produce remain, of profitable culture.

The county is well watered; and contains several ponds of some extent, the scenery in the neighborhood of which is picturesque and beautiful. Some of the situations on the Merrimack and many on the sea-shore are commanding in their position, and present views of large extent and great variety and beauty.

The farmers in Essex are particularly favored in respect to markets. Boston is easily accessible to most parts of this county, being from its farthest point not more than forty miles distant; and the large commercial and manufacturing towns of Salem, Lynn, Newburyport, Marblehead, Danvers, and Lowell, furnish a ready demand for whatever the farmer will produce. Of the whole population in Essex, there is reason to believe that not one-fifth part are engaged, properly speaking, in agriculture. The remaining four parts are consumers, not producers. The county of Essex is essentially a commercial and manufacturing district. Besides what may be called marketing, including the selling of hay, she sends no agricultural produce away; and she imports largely of bread-stuffs, vegetables, dairy-produce, mutton, beef and pork, together with a great amount of oats and corn for horse-feed. Rye is cultivated to a small extent, and the bread of the population is almost entirely composed of the superfine flour of western New York and the middle states.

Size of farms.—The average size of the farms in Essex, will not exceed one hundred acres, and farms of three or four hundred acres are scarcely to be found. The population of the county becoming daily more numerous, the land is continually undergoing subdivisions; and a large proportion of the persons engaged in the manufacturing and mechanic arts, are anxious to secure to themselves small parcels of land, for the sake of keeping a cow or raising their own fruits and vegetables.

Farming in the county is scarcely pursued as a distinct or exclusive profession; but as subsidiary to some other business or pursuit. In this way it has been eminently conducive to health, and productive of innumerable comforts; but no fair experiment has been made of it under the fair advantages of capital and labor and exclusive enterprise and attention, as matter of pecuniary income and profit.

From the same.

SALT HAY.

A large amount of salt hay is cut in the county. The marshes in Saugus, Lynn, Essex, Ipswich. Rowley, Newbury, and Salisbury, are extensive and productive.

The grasses produced on the salt marshes are various in kind and value. I prefer to give the common names, though these names may be regarded as local and provincial.

Black grass—deemed the best product: grows on the higher parts of the marsh, where it is only occasionally flooded by the tide; it is often thick and heavy, and it is desirable that it should be cut early. When well cured it is much relished by cattle; and deemed of almost equal value as the best English hay. I have seen this grass growing luxuriantly high up on the upland, where the seed was dropped from the cart; and it would be well worth the experiment to test its value as a cultivated grass in such locations. A farmer in Ipswich is of opinion, that if this grass is not cut very early, it should be cut very late, after the season of the fly has passed, which is apt to impregnate it, and occasion maggots in the mow, offensive to cattle. Other farmers deem this matter of little moment. The cattle themselves ought to be judges in the case.

The next grass is the *red grass* or *fox grass*, a very fine reedy grass, abundant and excellent.

The next is *goose grass*, deemed excellent, but not abundant. Sheep, it is said, will entirely destroy this grass, if suffered to feed on the marshes.

Branch grass, a short reedy grass, resembling much the fox grass, and by some persons pronounced the same; it branches much, and from this circumstauce derives its name; it is not abundant, but the hay is much valued.

Sedge, a pointed long flat-leaf, grows in low places and on the sides of creeks, much valued when not too large.

Thatch, a grass differing little from sedge, which grows in creeks as high as the tide rises; and is cut principally for litter or manure.

The average product of well-managed salt marshes is from three-fourths of a ton to one and a quarter ton. The hay is valued at half the price of English hay. In Salem and Boston markets, where it is purchased for a change of diet or to be mixed with English, it usually bring two-thirds of the price of English.

The farmers in the interior of the county, even at a distance of fifteen miles or more from the sea-shore, are glad to own or hire a piece of salt marsh, considering a portion of this fodder of great service to the health of their stock. A shrewd farmer in Lynn considers salt hay as worth five dollars a ton, merely to spread upon his grass land for manure. His judgment is to be relied on. It is stated likewise that those farmers, who carry it into the interior in a green state and cure it in their fields, find this process almost equal to a top-dressing of manure. This comes undoubtedly from the salts, which it deposites. The quantity of salt hay which is cut, enables the farmers to sell much of their English hay, without injury to their farms. These lands, according to their situation, are valued at from ten to fifty dollars per acre. Their value is likely to be much increased in many places from improvements of which I shall speak presently.

Considerable quantities of fresh meadow or swale hay is cut; but it is composed of aquatic plants, which contain little nourishment; and is of comparatively little value. The manure of cattle fed upon it or littered with it is of inferior quality.

From the same.

ASHES AS MANURE.

The farmers on Long Island have been accustomed to send to towns on our sea-shore, to Marblehead for example, to purchase for their wheat fields, our leeched ashes, at ten cents per bushel;

these contain a good deal of lime, which had been used by the soapboilers.* They ascertained that there was an advantage in it. It is known likewise, that foreign agents are visiting different towns and places on the sea-board, to purchase the refuse bones, and the animal carbon, after it has been used by the sugar refineries, in order to enrich the wheat fields in Europe, which have been, for the last two years, to a considerable extent, and to our great disgrace, the granaries of the United States.

From the same.

NEAT CATTLE.

Essex county is not a grazing territory. Few cattle are raised in it. The stock generally to be found in it is what is called our "native stock," which is a mixture of no certain origin; but in which the Devon race greatly preponderates.

Some cows, which have been owned in Essex, have probably never been exceeded, for their dairy produce, by any in any part of the country. The Oakes cow, owned in Danvers, made in 1813, 180 lbs. of butter, in 1814, 300 lbs.: in 1815, over 400 lbs.; in 1816, 484¼ lbs. At the same time, the family reserved one quart of milk per day for their own use; and she suckled four calves four weeks each in the course of those years. She made in one week 19¼ lbs. butter; and she averaged over 16 lbs. of butter per week, for three months in succession.

The Nourse cow, owned in North Salem, made 20 lbs. of butter in one week; and averaged 14 lbs. butter per week for four successive months.

The Haverhill heifer, two to three years old, produced 14 lbs. of butter in a week after her calf was killed at six weeks old; and more than 18 lbs. of butter in the ten days after her calf was killed. These cows were all of native stock.

The largest amount of milk given in one day by the Oakes cow, is 44½ lbs. In the case of the two first cows, they were fed in the most liberal manner, with meal and their own skim milk. In the case of the heifer, the feed was grass and pumpkins.

I subjoin a list of a few other cows in the county, whose yield is well authenticated.

1. Cow owned by John Barr, in Salem.

In 274 days the weight of milk was		7611 lbs.
1822.	No. of quarts, beer measure,	2965½
1823.	In 268 days, weight of milk was	7517 lbs.
	No. of quarts, beer measure,	2923.

The sales from this cow, including the calf at 5 dollars, and milk at 5 cents per quart, in 1822, was $153.25. In 1823, $151.15.

2. Cow. John Stone, Marblehead. From June to October, this cow averaged 11 lbs. of butter per week.

3. Cow. N. Pierce, Salem. 3,528 quarts milk per year,—nearly 10 quarts per day.

4. Jeremiah Stickney, Rowley. 19 quarts daily; calf at six weeks old weighed 196 lbs.—gain 2¼ lbs. per day.

5. Cow. Isaac Osgood, Andover. 17 quarts of milk per day; made 50 lbs. of butter in the month of June.

6. Cow. S. Noah, Danvers. In 148 days from 2d May, gave 587½ gallons milk;—more than four gallons per day for that time.

7. Cow. T. Flanders, Haverhill. From 20th April to 22d September, besides 46½ gallons milk used for family, made 163 lbs. 4 oz. butter.

8. Cow. Daniel Putnam, Danvers. "This cow calved May 21st. The calf was sold June 20th for $7 62½. During the 30 days that the calf sucked there were made from her milk 17 lbs. of butter. From June 20th to September 26th (14 weeks) she gave 3370 lbs. of milk, or more than 34 lbs. 6 oz. per day. The greatest quantity on any one day was 45 lbs., or 17½ quarts. The weight of a quart of her milk is 2 lbs. 9 oz. The greatest quantity in one week was 288 lbs. The quantity of butter made in the same 14 weeks was 139 lbs. The greatest amount in one week was 12 lbs. 2 oz."

9. Cow. Owned by William Osborn, Salem. The milk of this cow from January 24th to April 10th, was 3127 lbs., varying from 33 to 48 lbs. per day, averaging 40¼ lbs. per day during that time.

10. Cow. Owned by Richard Eliot, Danvers. This cow's milk gave 16 lbs. of butter in one week; and she yielded on an average from 15 to 18 quarts per day, beer measure, for a length of time.

All these cows were what is denominated our native stock. An intelligent gentleman, the owner of an extraordinary cow in the interior, remarks, in a letter detailing her yield, what is highly important to be remembered. "From the experience I have had with this cow, I feel quite sure that many cows, which have been considered quite ordinary, might, by kind and gentle treatment, good and *regular* feeding, and proper care in milking, have ranked among the first rate."

The yield of a cow now owned in Andover, is remarkable. Her origin is not known, but her appearance indicated a mixed blood; and I was led to believe she partook of the Yorkshire blood, a race of cattle which I have found in the neighborhood of Moultenboro' and Canterbury, N. H., but whose introduction I am not able to trace.

In 1836, besides supplying the family with cream and milk, there were sold 127¾ gallons milk

at 14 cents per gallon,	$17 88
166 lbs. butter at 25 cents,	41 50
Calf sold,	8 00
	$67 38

"The keeping was good pasture and swill of the house, including the skim milk, with three pints of meal per day." These statements show, in a strong light, the difference between a good and a poor cow; and the utility of liberal keeping.

The difference in the butter properties of different cows is not generally considered. In a yard of five cows, upon repeated trials, made at similar times, and as near as could be under the same circumstances, by a farmer in this county, the difference in the yield of cream upon 9 inches of milk, was found to be as 13 to 3.

Attempts have been made to introduce some improved foreign stocks into the county; the Alderney, the Holderness, and the improved Durham short-horn. These experiments are report-

---

* And also, a much larger proportion of the carbonate and phosphate of lime, as original ingredients of all wood-ashes.—Ed. Far. Reg.

ed to have been satisfactory to those who have made them; but I have been unable to procure any exact returns. Admiral Sir Isaac Coffin presented a valuable improved Durham short-horn bull and cow to the Massachusetts Agricultural Society, which were placed on the farm of a gentleman in Salem, who retains some of the half-blood stock. The amount of the yield in milk of this short-horned cow is mislaid; but the owner states from recollection, "that her milk night and morning, weighed 48 lbs., when she had nothing more than pasture feed in June." Respecting this stock, the gentleman adds,—"In my opinion, they combine the two qualities of milk and beef in a greater degree, than any other stock I am acquainted with. With me, the pure bloods, and a large proportion of the mixed blood, have proved great milkers, and, when not in milk, take on flesh very rapidly. I have slaughtered two half-blood heifers, which have weighed at four years old over 700 lbs. A pair of half-blood steers, at four years old, became so very fat from common keep, that I was induced to dispose of them to the butchers; they weighed 1100 lbs. each. The greatest objection to them, in my opinion, is, that they incline to go dry a longer time than our native stock."

My own experience differs somewhat from the respectable authority just given. I have had some of the full-blood and some of the mixed breed; and I am not able to say any thing in favor of their milking properties. I have seen some remarkably fine specimens of early maturity and thrift among them; and more beautiful models of cattle than some specimens which I have seen of them, I believe are no where to be met with.

Another public-spirited gentleman, in Bradford, imported some of this fine stock for his farm. His expectations do not appear to have been fully answered, though I was not able to obtain any exact information of their yield in milk or butter. From the letter of his correspondent, whom he employed to procure these fine animals for him without limit as to expense, I extract as follows. "I must observe that this breed of stock has not been held, of late years, in great estimation for milking." He adds, that "short-horns are only calculated for the best and most powerful land; on poor soils they will do nothing. The most improved plan of keeping them in winter is to have them loose in open warm hovels, two or four together. The bulls you will find it necessary to keep in altogether, from one year old. The milch cows are kept at the stake in enclosed houses; and turned out a short time in the day time—they bear the cold badly."

There is another very strong testimony, that of Mr. Shiriff, who travelled in this country for agricultural information in 1834-5; and who is pronounced, by one of the most eminent breeders of the Durham short-horns in England, a farmer of the first rank. In his journal, he remarks,—"There was a fine short-horn bull, intended to improve the dairy stock, which I did not see. I took the liberty of advising the cross to be tried on a small scale, believing the short-horns the worst milking breed in Britain."

I give these opposite authorities, in justice to the agricultural community. The subject deserves much farther inquiry, and the test of actual experiment. On this account, it were greatly to be desired, that the gentlemen who own this fine stock, and from the most public-spirited designs have introduced them into the country, would give the public exact statements of their product. Some oxen in the county, descended from the short-horned bull Admiral in the second generation are very fine cattle, in point of size, docility, condition, and work. I have seen the importations of this stock made by the Ohio Company; and it seems impossible to imagine animals of more perfect symmetry and beauty; or of better promise in point of thrift and condition. They may, however, suit far better the luxuriant meadows of Ohio and Kentucky, than our bleak and short pastures.

From the same.

MANURES.

Much and increasing attention is paid throughout the county to the saving of manures and the formation of compost. Vastly more remains to be done. In many parts of the county, cellars are considered a necessary appendage to the barn, where the manure is sheltered from the sun; and, by some of the most careful, from the external air likewise. A Danvers farmer, on whose good judgment I place great confidence, expresses his strong conviction, that the value of his manure is doubled in a closed cellar, in comparison with it under the former mode of exposure to the sun, and air, and rain. In most of these cases, the barn is placed on a side hill; the cellar is high enough to load in and turn the team and cart; and a trap door is in the barn floor, so that bog-mud, litter, or other refuse, may be easily thrown in to be formed into compost by the store hogs, which are put there to work, and which faithfully earn their living. In two places, I found provision made for saving all the liquid manure from the stalls and the barn yards. It was conveyed by gutters into a capacious cistern, from which it was occasionally pumped into a watering cask, like that used in the streets of cities, and distributed on the grass ground. This was done with great advantage. The liquid manure of a large herd of cattle, could it be properly husbanded, would be of equal value as the solid manure. The subject of saving manures, and collecting and compounding them, is a matter which cannot be too strongly pressed upon the attention of farmers. It is the very life-blood of successful agriculture.

The subject of the application of manures, whether in a perfectly green and unfermented, or in a decomposed state, has been matter of much inquiry among the Essex farmers. The general impression is, that they should be used in a green state, as their most valuable parts are lost in the progress of decomposition. The philosophy of manures is as little understood as the philosophy of digestion. Nature draws a veil over many of her processes, which no prying curiosity has been able to raise, and no solicitude has induced her to uncover these operations. By what means the food received into the stomach goes, in its wonderful subdivisions and changes, to the formation of blood and bone, muscles and skin, hair and nails, is a matter about which we know as much as we know how the food of plants is taken up and elaborated, and goes, according to the seed which is sown, to the formation of the stem and leaves, the coloring and taste, the flowers and fruit. It may operate as a stimulant, waking the dormant powers of the earth into action. It may serve as the substance, out of which the plants are to be formed; and to a degree, the evidence of this is perfect. It may so affect the earth and the atmosphere, that these great reservoirs of the elements of vegetable and animal life, may at once furnish their proper and required contributions. But conjecture here is in a great measure idle. We may talk very learnedly on the subject without knowing any thing about it, or being able to communicate any valuable information. On this matter, experience and intelligent observation must be our guides. In actual bulk, manure, which is thoroughly decomposed, loses one-half. Its activity, its power of producing heat, one of the ascertained principles of vegetable life, is likewise lost. On these accounts, it is obviously best to apply it green. The experience of intelligent farmers almost universally confirms this. But unfermented manure, if applied immediately to the roots of plants, may, by too much action, or too much heat, or by supplying their food in too lavish or too concentrated a form, destroy them. There is no danger from this when manures are spread and ploughed under the soil, or scattered over its surface. But where their immediate action is desired in the soil, it is important, before they are taken out of the yard, that they should be in a partially decomposed state, or rather in an active state; and for that reason, they should be turned over and thrown into heaps in the cattle yards in the spring, that they may become in a degree warm before they are applied. If they are to be applied directly to the roots of crops, they should be either mixed with earth, or so far advanced in their decomposition, that no evil may result from the heat of their first action; and that they may be so subdivided and dissolved as to be in a condition to be at once taken up by the absorbent vessels of the plants.

These views will explain what I wish to say in regard to our great crop, Indian corn; and what long experience and observation have confirmed. The question is often asked, shall the manure be spread or placed in the hill? I answer, do both. Its immediate action is needed to bring the plant forward as soon as possible; and therefore partially decomposed manure should be placed in the hill. It is equally necessary that the plant should not suffer from want when its roots spread themselves beyond the hill in pursuit of food. The unfermented manure, spread and ploughed in lightly, will be in a condition for the use of the fibrous roots when they advance to receive it. Another question often proposed is, should the manure which is spread be ploughed in deeply, or covered lightly, or simply laid on the surface? If the plant to be cultivated be a tap-rooted plant, it will find the manure, though it should be buried deeply. If it has a spreading and fibrous root, like all the cereal grains, the nearer it is to the surface, without being entirely exposed on the top of it, the more available it is to the growth of the plant. If laid upon the surface and not covered, much of it must inevitably be lost by the sun and rain and wind. In respect to Indian corn, especially recollecting the cold seasons of the two last years, it is important by every possible means to get the plant forward as fast as possible; and for that reason to select the warmest and the driest land; to manure with fine manure in the hill, and with unfermented manure spread broad cast; and to plant as soon as the land can be made dry and warm enough to receive the seed. There is no crop that will better reward the most liberal cultivation.

In respect to the manuring of wheat, fermented and finely dissolved manures may be safely applied the year of its being sown; but not so with unfermented manures. In general, it is best that the crop which precedes the wheat, rather than the wheat itself, should be manured.

In regard to the application of manure to potatoes, the almost universal opinion has been, that when manured in the hill, the seed should be laid upon the manure. Many farmers have reversed this practice; and now place the manure upon the seed, they say, with superior advantage.

Besides barn manures, slaughter-house manure has been used with great effect; but it is necessary it should be mixed with loam. Night soil, mixed in the proportion of one part of night soil to four of loam or fine gravel, has been used with extraordinary efficacy, upon peat or bog meadow. Muscle bed is much used, especially by the Danvers farmers, for their onions and vegetables for the market. It costs in Salem about one dollar for a large horse load, and is applied liberally. At Manchester, where it is quite accessible, it is used with great advantage either as a top-dressing or ploughed in. At Beverly, I have seen its excellent and lasting effects as a top-dressing on grass land. A farmer in Danvers states that a gondola, containing eight four-ox loads of muscle bed, will deliver its cargo near to New Mills, for seven dollars. This is a low price. He is accustomed to spread six or seven loads to the acre, in winter, when frost will render it pliable. It will do well to apply it once in four or five years; oftener than this, it binds the land and renders it hard.

He says, it is of excellent use when applied to land which is to be laid down to grass with barley or oats. Its effects are lasting; and no other application will be required for years.

In the town of Essex, a great amount of clams are dug for fish-bait. The shells are much used for manure. The keeper of the alms-house in Essex, whose management is highly creditable, says, "as to the value of the clam-shells for manure, I think the broken and the whole shells very useful to low land, either to be spread on or ploughed in. They render the ground light and warm, and are very durable. They likewise enrich the land very much." The same may be said of oyster shells, which are obtained in some quantities in the cities.

The great amount of squashes mentioned in a former part of my report, as obtained from two acres of land, is in some measure to be ascribed to the use of fish oil or blubber oil. The farmer, living near the fishing village in Lynn, obtains in the winter time a great quantity of fish livers and garbage. From this he procures the oil. After his casks are emptied of their oil, he fills them with water, which remains some time; and this water, thus considerably charged with oil, he applies to his squash vines. The effects are powerful.

One farmer, whose farm lies on the sea, has this year made some trials of fish as a manure. The

Munhaden, Alewives, or Hardheads, as they are called, come to the shores in the early part of the season, in great numbers, and are easily taken in seines. In the southern parts of this state, and in Rhode Island, they are used in great quantities; either spread upon the grass land, or laid near to, or placed in, the hill of corn. They are very powerful; but their effects not lasting. The animal matter contained in them is considerable; and the bones are composed of phosphate of lime, which is a strong and active manure. The great objection to their use is, that to a person not interested, they render the air extremely offensive. Not so to those who find a profit in their application. To most men, a golden breeze is always fragrant. There are other marine manures of great value. I have found sea sand, put in the hill of potatoes, in low land, of great efficacy. My experience in this matter is not singular. The silicious matter divides the soil; and the salt which adheres to it serves to stimulate the plant. Sea sand has been used with advantage at Sandy Bay. The marine plants are used with very beneficial results. The eel-grass is of little value excepting as litter. Nothing seems more grateful or healthful to swine than an abundance of this grass in their sties. It serves to increase the compost heap; but it becomes light and does not leave much when dried. Rock weed and kelp are valuable when ploughed in; but they are used to most advantage when applied directly as a top-dressing upon grass land. Then their effects are remarkable, and no more efficacious manure can be used. If left in heaps for any length of time, they soon become heated and decomposed; and are gone.

The refuse of the comb manufactories, horn tips and horn shavings, are greatly valued as manures. The refuse of the glue manufactories, are used with great advantage. Ashes, leeched or crude, have been applied by different individuals with various success. A farmer of high authority, in Newberry, states:—"I think leeched ashes very valuable to spread on grass land; likewise for onions and grain. I use twenty or thirty cart loads. I gave this year three dollars per load of fifty bushels." A respectable farmer states, that he deems them of no use, unless applied in conjunction with other manure, and then of great efficacy. In their application upon a rich loam to corn, both in the hill and spread round the hill at the first hoeing, I have seen no beneficial results from them. The experience of J. Buel, Esq., of Albany, he told me, in the use of ashes, coincides with mine. Leeched ashes, or soap-boilers' waste, which contains always a quantity of lime, I have used with advantage for wheat. These different results may depend upon soil, season, modes of application, or various circumstances, which we have not yet been able to determine. There can be no doubt of their efficacy and utility in some cases. There are many good authorities to this effect.

The ashes of anthracite coal have been spread upon grass land in Gloucester, with obvious advantage. Peat ashes have been used in Newbury on grass ground with much advantage; but in excess, or when frequently repeated, their effects are stated to be injurious.

The use of gypsum in the interior of the county, has been successful; but not so on the seaboard. In Haverhill, Andover, and Methuen, its effects are marked; and, in some cases, are as distinctly observable in parts of a field on which it has been used, where the other parts have been omitted in the distribution, as the enclosure is by the fences. The testimony of an experienced and careful farmer in the interior is subjoined. "As to gypsum, I have used it with good success. It is the opinion of many of our farmers that it injures the land. But from actual observation, I have been led to believe otherwise. There are pastures in our vicinity, in which plaster has been used twenty years without ploughing; and they are now the best pastures in the vicinity. I think, that in some instances, our crops have been doubled by the use of it. We usually apply about two and a half bushels to the acre." This is a large application; and it is questionable, whether the benefits are large in proportion to the quantity applied. In Berkshire county, a bushel to an acre is deemed ample.

Of the ploughing in of green crops for enriching land, I know of but one decisive experiment; and this made by one of the most intelligent and best friends of the farming interest in the county. This was made in 1832-3; and honored by the premium of the Essex Agricultural Society. This was a crop of buckwheat ploughed in when in full flower. "The committee say, on examining the land on which the experiment had been made, they found the growing crop thereon was in a much more promising and flourishing state, and much better sustained the severity of the drought, to which all lands in that vicinity were then exposed, than the crops of corn which were then growing on the contiguous ground of a similar soil; and which had been cultivated and manured in the ordinary manner." Besides the ploughing in of the green crop, the field was manured in the same manner as the other lands with which it is here compared.

The price of manure, in Essex county, is extraordinary. Three dollars and a half a cord for stable manure have been paid at the stables in Methuen; $4 50 in Andover; and I have known $6 paid in Salem for compost of night soil and muscle bed. A farmer in Middlesex, told me he was content to pay $5 50, for unmixed cow manure in Lowell, and cart it a distance of four miles. The expenses and trouble of transportation are often fully equal to half the cost of manure. It is surprising to find farmers willing to pay such prices; and it would be well to inquire, whether it would not be expedient to keep one man, whose sole business it should be, whenever the team could be spared, to collect the materials for a compost heap, which are to be found in abundance in almost every vicinity for the labor of going after them. At the prices above-named, manure may well be called the gold dust of the farmer.

I am unwilling to quit this homely subject without remarking, what always strikes me with great force, that beautiful and sublime miracle of the divine Providence, by which the very refuse, which man casts out and loathes, returns to bless him in the verdant fields, and the teeming harvests, in the most fragrant flowers, the most delicious fruits, and the most substantial products.

The use of clover sowed among grain and even among corn for ploughing in as the means of renovating the soil, has not prevailed within my knowledge in Essex county; but is commended to their attention as likely to be eminently beneficial. For this purpose we recommend most strongly the June, southern, or early clover so called.

No considerable experiments in the use of lime have come under my notice. A farmer in Haverhill, who has applied lime as a top-dressing upon his grass lands, is disappointed in his expectations of advantage from it. Extensive beds of clay-marl have been discovered; and this has been applied with great advantage on peat lands or bog meadows.

From the same.

MILK WEED.

Experiments have been made with the stalk of the common milk weed, in procuring from it a thead or fibre, capable, as was represented, of making a fabric as fine and strong as flax or silk. A patent was secured for the discovery, but it has not been pursued.

GENERAL WANT OF LIME IN THE SOILS OF MASSACHUSETTS AND MAINE, THE CAUSE OF THEIR UNFITNESS FOR THE PRODUCTION OF WHEAT.

Letter from the Geological Surveyor of Maine and Massachusetts to the Rev. Henry Colman, Commissioner of the Agricultural Survey of Massachusetts.

[We rejoice that the important truth which we have stated in the above caption, and which has been so often repeated in our remarks in this journal, is now presented in a manner, and on authority which, it may be expected, will command more respect and attention, than has been given to our attempts to make known and to enforce the same general proposition. Let the naturally poor (or "acid") soils of New England be but limed, or marled, and the alleged general incapacity to produce wheat will no longer exist.—Ed. Far. Reg.

Boston, Jan. 15th, 1838.

Dear Sir:—In accordance with your request, I now beg leave to offer you a few general remarks on the subject of soils and the raising of wheat crops in the New England States.

A general opinion has prevailed in the community that our section of country was incapable of producing its own supply of bread-stuff, owing to the nature of the climate and the composition of the soil. So far as the climate is concerned, there is not the least difficulty in raising any kind of grain, but it is true that many of our soils require some modification, by means chiefly of mineral manures, before they can be made productive.

I have, for several years, been an attentive observer of the management of soils, and believe that I have a good reason to conclude from my observations that the amelioration of the soils of Massachusetts, may be conducted in such a manner as to render them very productive at small expense.

I find, by chemical examination of several remarkable soils, that a very minute quantity of carbonate of lime, viz. from 1 to 2 per cent., is amply sufficient to render them capable of bearing heavy crops of good wheat. I am also satisfied that a soil is incapable of producing wheat of good quality, if it does not contain carbonate of lime; for this substance is an essential ingredient of the grain.

I have found during my geological researches in Maine, that those soils which were derived from the disintegration and decomposition of limestone rocks, were the most remarkable for their wheat crops. Such districts are very extensive in Maine, and will ere long become exceedingly valuable as grain soils.

I have seen, on a single farm of less than 30 acres of unmanured land upon the Aroostook river in Maine, no less than 1000 bushels of grain, principally wheat, which was raised this last summer. The soil is alluvial and derived from limestone. In York and Oxford counties, I also noticed very excellent crops of wheat in soils derived from the disintegration of limestone, which alternates with gneiss. The whole of the district between Houlton and the Aroostook river, which is a portion of the public lands, is a most valuable wheat soil of immense importance to our country; north of the Aroostook to the St. John, a similar tract of good soil exists, which in the course of time will become a most valuable farming country.

In the western part of Maine and throughout a large portion of Massachusetts the soil is wanting in lime, and is frequently charged with sulphate of iron. Such soils require liming in order to render them productive. In general we may say that wherever ferruginous waters percolate from a soil, that soil requires treatment with lime. The sulphate of iron in this case is decomposed by the lime or by the carbonate of lime, and gypsum is the resulting product, while the iron is left inert. Now we have a very simple calculation to make as to the quantity of lime required for a soil which is destitute of it, or which contains matters to be decomposed by it. Calculate by a simple trial how much lime is required for a given measure of soil, and then calculate the superficial contents of the field and multiply it by the depth to which the lime will extend; other things being equal, one per cent. of lime will be sufficient. Ground bones form a valuable manure, and there are mills now at work preparing them for our farmers. Mr. Winchester, the soapmaker, formerly threw his refuse bones into the sea; but lately, I understand, he has hired laborers to dig them up for agricultural use.

Burnt bones are easily crushed to powder in a break mill, and will answer admirably as a top-dressing. A few fagots are sufficient to burn a large heap of bones, since the fat they contain aids in the combustion.* The refuse bone black of our sugar refineries is also a very valuable manure, insomuch that proposals were made to the East

---

* We should consider it very far better economy to use this "fat" contained in bones, as additional manure, instead of as fuel to burn and soften the harder parts.—Ed. Far. Reg.

Boston Sugar Refinery, by Havre merchants, to send here for all the refuse bone black, which they wished to purchase for agricultural use in France.

Is it not a shameful fact, that the French farmers are so much our superiors, that they can afford to send here for manure, and then raise wheat, beans, corn, and other vegetables, cheap enough to supply a large share to our market? Such you will notice by the importations last year is the fact.

If our farmers knew more respecting the chemical nature and methods of amending their soils, then we might indeed look to our own fields for bread, but alas! there is a great deal of empiricism in agriculture, and it is no wonder that farmers distrust what they call "book learning," when they obtain so very little practical information from it. The fault is on both sides, first, because the books we have at present are very inaccurate; secondly, because the farmers generally do not know how to apply the information contained in books, since they do not know the composition of the soils in question.

If the Agricultural Survey is supported as it ought to be, and a degree of liberality is extended towards it, such as its importance merits, then we should soon be able to say with truth, that agriculture is a science.

In order that we should come to this result, we have to learn 1st, the geological origin; 2d, geological distribution; 3d, chemical composition; 4th, capabilities of soils. These three topics I shall endeavor to discuss in my Geological Report to the legislatures of the two states of Massachusetts and Maine. We must not expect to make a perfect work at once; several years of assiduous labor must be devoted to each of the questions before us, before a good book on agriculture can be produced. All the old works are too inaccurate to be relied upon. The light of modern science is required.

There are, I believe, several other questions proposed for discussion; but time will not allow me at present to enter upon them.

I will therefore now conclude this letter by offering you my best wishes for your success in the Agricultural Survey of our state; and shall be most happy, when my present labors are completed, to co-operate actively in your important avocations. Most respectfully, your ob't. serv't.,

CHARLES T. JACKSON.

For the Farmers' Register.

WHICH IS THE MOST PRODUCTIVE CORN?

Mathews, Feb. 21st, 1838.

Those farmers who have had sufficient experience with the Maryland twin corn, are requested to state which is the most productive—that or the common corn? No subject in our mode of farming is more important, than a satisfactory knowledge of the most prolific species of corn. It is our staple, and if, as has been asserted, the twin corn will produce 20 per cent. more than the ordinary corn he who will satisfactorily establish such a fact would deserve a crown of laurel.

S.

From the Quarterly Journal of Agriculture.

ON FATTENING CATTLE ON DIFFERENT KINDS OF FOOD.*

By Mr. JOHN BRODIE, Amisfield Mains, Haddington.

Agreeably to the conditions, the Committee of Management, immediately after I had intimated my intention of competing, appointed an efficient sub-committee to assist me in dividing a lot of twenty Aberdeenshire polled cattle, into four lots of five each, and also to superintend and report upon the manner in which the experiments were conducted.

The cattle were bought at Falkirk on the 12th of October, and on the 24th were lotted, and put into separate yards, each of which had ample space, and shelter from the weather, by covered sheds, for the several lots which were distributed among them; and conceiving that the object which the Agricultural Society had in view in offering this premium, was to find out a substitute for turnips, each lot of cattle had a mixture of food allowed them, with the exception of lot No. 1, which was altogether fed upon turnips and straw, and may on that account be designated the trial lot; No. 2 had half the quantity or weight of turnips which was allowed to No. 1, with 30 lb. of linseed-oil cakes, as a substitute for the remainder of the turnips; lot No. 3 had the same weight of turnips which was given to No. 2, and had ground corn in place of the oil-cakes; the fourth lot got offal from a grain whisky distillery, and a portion of ground beans, which was mixed into their draff every morning. By following out this arrangement, we have ascertained the quantity of turnips saved; the value of the turnips in feeding by themselves, contrasted with the other substances; and their value as an auxiliary feeding when used with those richer substances, which, without some coarser food, will neither be an economical nor a beneficial food for cattle. All the lots had fresh straw given to them daily, which was not weighed, and below is a statement of the food consumed, and the expense incurred in the fattening of each lot:—

Lot No. 1. fed on Turnips.

1836.					
October	12. To	price of five cattle,	£55	0	0
	24.	10 days' keep of ditto on turnips and straw, at 8*d*.	1	13	4
January	1.	34 tons white globe turnips, at 8*s*. 4*d*. per ton, since 24 October till this date, being 10 cwt. per day,	14	3	4
April	7.	38 tons, 16 cwt. ruta-baga, at 12*s*. 6*d*. per ton, since 1st January till this date, being 8 cwt. per day,	24	5	0
			£95	1	8

At this date the Judges appointed by the Committee of Management,

---

* Report made by Mr. Brodie in 1837 on this subject in competition for the premium offered by the United East Lothian Agricultural Society.—EDITOR.

1836.		inspected the cattle, and reported their value to be £82.			
June	7.	21 tons, 9 cwt. ruta-baga, since 7th April till this date, at 12*s*. 6*d*.	£13	8	2
		Brought over,	95	1	8
			£108	9	10

The average expense of the keep of this lot is about 6*s*. 3*d*. per week each beast.

Lot No. 2. fed on Turnips and Oil-Cakes.

October	12.	To price of five cattle,	£55	0	0
	24.	10 days' keep on turnips and straw, at 8*d*.,	1	13	4
January	1.	17 tons white globe turnips, at 8*s*. 4*d*.	7	1	8
April	7.	19 tons, 8 cwt. ruta-baga, at 12*s*. 6*d*.	12	2	6
		1 ton, 18 cwt. foreign linseed-oil cakes, at £7, 15*s*. per ton, since 16th November till this date, being 30 lb. per day,	14	14	6
			£90	12	0
		Estimated value at this date, £88, 10*s*.			
June	7.	10 tons, 15½ cwt. ruta-baga, at 12*s*. 6*d*.	6	14	1
		16 cwt. 38 lb. linseed cakes, at £8,	6	10	8
			£103	16	9

The average expense of the keep of this lot, is about 5*s*. 9*d*. per week, each beast.

Lot No. 3. fed on Turnips and Ground Corn.

October	12.	To price of five cattle,	£55	0	0
	24.	10 days' keep on turnips and straw, at 8*d*.,	1	13	2
		17 tons white globe turnips, at 8*s*. 4*d*.	7	1	8
April	7.	19 tons, 8 cwt. ruta-baga, at 12*s*. 6*d*,	12	2	6
		1 ton, 14 cwt. 98 lb. of bean-meal, or 63 bushels ground beans, weighing 62 lb. per bushel, at 5*s*.	15	15	0
		9 bushels bruised oats, at 3*s*. 6*d*.	1	11	6
			£93	4	0
		Estimated value at this date, £77.			
June	14.	10 tons, 14½ cwt. ruta-baga, at 12*s*. 6*d*.	6	14	1
		1 ton, 9 cwt. 100 lb. bean-meal, or 54 bushels ground beans, weighing 62 lb. per bushel, at 5*s*.	13	10	0
			£113	8	1

The average expense of the keep of this lot, is about 6*s*. 8*d*. per week each beast.

This lot had latterly the rough seeds of oatmeal, at 1½*d*. per bushel, as a mixture to the bean-meal, which are not charged, being worth the price as manure.

Lot No. 4. fed on Distillery Grains and Ground Beans.

1836.					
October	12.	To price of five cattle,	£55	0	0
	24.	10 days' keep on turnips and straw, at 8*d*.	1	13	4
November	7.	3 tons, 5 cwt. white globe turnips, at 8*s*. 4*d*.	1	7	1
April	7.	72 quarters draff, at 4*s*. 6*d*.	16	4	0
		60 puncheons dreg, at 2*s*. 6*d*.	7	10	0
		1 ton, 14 cwt. 62 lb. bean-meal, or 62 bushels ground beans, weighing 62lb. per bushel, at 5*s*.	15	10	0
			£97	4	5
		Estimated value at this date, £81, 10*s*.			
June	14.	37½ quarters draff, at 4*s*. 6*d*.	8	8	9
		28 puncheons dreg, at 2*s*. 6*d*.	3	10	0
		19 cwt. 104 lb. bean-meal, or 36 bushels ground beans, weighing 62 lb. per bushel, at 5*s*.	9	0	0
			£118	3	2

The average expense of the keep of this lot is about 7*s*. 2*d*. per week each beast.

At the commencement of these experiments, the different divisions of cattle had each their places, as well as kinds of food, allotted for them; and those of the trial lot, No. 1, whose feeding was destined to be turnips alone, from being the kind of food which they were formerly accustomed to, made a more immediate improvement than the cattle of the other lots, so much so indeed, that several of my friends who saw them during this period, could not believe that a proper division of the cattle had been made, as this lot was then, about the end of November, £5 better than any of the other lots.

By the above statement, it will be observed that the feeding of the lot upon turnips and oil-cakes, was the least expensive mode which was adopted in making the experiments; and that these cattle made the greatest improvement (although after ten or twelve days' trial with oil-cakes, they were so obstinate in refusing them, that it was found necessary to take away their allowance of turnips for some days, and give them water instead, before they were induced to begin). This was sufficiently proved by the marked difference in value put upon them by the judges appointed to report upon the comparative value of each lot, at the Society's Show in April. This continued in rather an increased degree during the remaining time they were here, particularly as contrasted with the trial lot, which was altogether fed upon turnips, having been estimated by good judges about the beginning of June, to be worth about forty shillings more each beast, than those of the trial lot.

The improvement of the cattle in lot No. 3 was much retarded by one of their number being naturally of such a restless disposition, that he himself would not take time to eat, nor would he allow the others to do so, and although the yard which they occupied was of sufficient size for a greater number, it was not until the turbulent ox was taken away and fed by himself, that the cattle made the improvement which they ought to have done; after that, however, a very perceptible improvement took place, and by adding a little to their daily allowance of ground beans, their value when killed, as it appears by the flesher's return, was very different from what it had been when valued comparatively with the other lots at the April show. This untoward circumstance, caused a greater expense in the keeping of this lot than would have been otherwise necessary.

In the charge against lot No. 4, it will be observed that keeping upon distillery offal is more expensive than the keeping of lots No. 2 and 3 with their half allowance of turnips. The turnips, however, were the produce of the farm, and the prices were fixed by the Committee, and high as they are, I could not have purchased turnips to carry here, unless by giving four or five shillings advance upon the ton weight; therefore a part of the charge against the distillery offal, will require to be set down for manure, and the same ought also to be deducted from the beans, which are charged at rather a full price.*

Upon the whole, it is evident by these experiments, that feeding with turnips as an auxiliary, has been the most advantageous mode of using turnips, as by the state it is apparent that if the cattle of lot No. 1 had only been allowed half the quantity of turnips which they consumed, and had got oil-cakes in lieu of the other half, as was given to lot No. 2, the expense of their keeping would have been lessened £4, 13*s*., and from superior quality their value would have been increased £10, making together £14, 13*s*.; therefore, by bestowing the remainder of the turnips, with the addition of oil-cakes, upon other five cattle, the realization upon the turnips eaten by lot No. 1, would have been £29, 6*s*. additional to what it has been.

These experiments were carried on for two months after the valuation was made at the show in April; as from an over supply in the market, caused by a scarcity of turnips, the cattle would not then have paid for their keep; but by continuing till June, I have been amply remunerated for all my outlay and trouble, without taking into account the great advantage of the additional and enriched manure of twenty cattle fattening upon the farm, where ten only could have been kept, had turnips alone been used for that purpose; and to any person at all acquainted with agriculture, it must be evident that one cart-load of manure made by cattle thus fed, will be at least equal to two, if the cattle had got only straw and water.

The above experiments, which are corroborated by those conducted last season by Messrs. Andrew Howden and Alexander Brodie, junior, tend to show that the winter feeding of cattle is more capable of successful extension by those who have a sufficiency of straw, but who have not such abundance of turnips, as to be able to make all their straw into manure by cattle upon full feeding, than was formerly imagined.

From the cattle having travelled to Glasgow, their weight has not turned out in the manner it would have done had they been slaughtered nearer home; besides, from a very great dulness taking place in the butcher market there, Mr. William Thomson, who purchased the cattle, found great difficulty in disposing of the beef so quickly as the time of lifting required, therefore lot No. 1, which was first slaughtered, had an advantage by not being allowed to fall off from being kept after being driven such a distance.

Live Weight of Cattle before being travelled to Glasgow.

* We think that in all such calculations, the value of any produce consumed on the farm ought to be taken at what it really costs the farmer to raise it, and not at its market price, for that includes the profit on it; and it is surely unreasonable to attempt to superadd a profit above the profit included in its market price.—Editor.

From the Quarterly Journal of Agriculture.

KYAN'S PROCESS FOR THE PREVENTION OF DRY-ROT IN TIMBER.

Until the privileges of the patent granted to this invaluable discovery were secured by act of parliament to a company, its excellence made little impression on the proprietors of wooded properties. The company, aware that no conviction inspires confidence like that derived from reference to facts, has never ceased, since its formation, to adduce the most authenticated facts in favor of the efficacy of this simple process. Like every great practical improvement, it is now, slowly it is true, but not less securely, establishing itself in public confidence. The whole process, we believe, consists simply of steeping timber in a solution of corrosive sublimate, the *bi-chloride of mercury*. Mr. Kyan, in claiming credit for this process, does not pretend to the discovery of any new principle; it is only in the application of a known principle to practical purposes that his claim consists. It was well known before that a solution of corrosive sublimate was commonly used for the preservation of cases of morbid diseases in anatomical preparations, and even that the delicate texture of the brain was preserved in a firm state by it; but it was never known, or even conjectured, until Mr. Kyan published the fact, that it would also preserve timber from decay, that it would prevent that internal decomposition in timber, which terminates in what is commonly termed dry-rot, a term quite descriptive of the effect of the disease.

For many years Mr. Kyan endeavored to impress on the admiralty the importance of his discovery in preserving the timber intended to be used in ship-building, but to no purpose. It is no wonder so simple a process did not at once obtain credence of its efficacy. At length, however, so many facts of its efficacy in preserving isolated pieces of timber from destruction in unfavorable circumstances were adduced by Mr. Kyan to architects and others, that a parliamentary inquiry was instituted, and the evidence published. Sir Robert Smirke, among other eminent architects and timber-merchants who were examined, stated before the committee, that he had taken a cut from a log of Canadian yellow pine, poplar, and Scotch fir, after being prepared in Kyan's process, and put them in cess-pools and common sewers for six months, in hot-bed compost-frames for other six months, in flower-border for the succeeding six months, and had them watered along with the flowers, and in damped cellars, excluded from the air for the last six months, but contrive all he could, he could not rot them. Every one is aware these soft pieces of timber, unprepared, would have rotted under such treatment in a very short time. This evidence, however, leaves the question unanswered, whether it is necessary, in the first instance, to season the timber thoroughly before the process will preserve it from dry-rot. If the utility of the process were even confined to seasoned timber, it would still be a valuable discovery, for the ships of the navy that were affected with dry-rot were all built of seasoned timber of at least three years' exposure to the air; but before the timber is considered seasoned only conceive the destruction occasioned by the dry-rot. During an inspection which took place in Deptford yard, in the months of October, November, and December. 1801, to ascertain the quantity of defective timber after the lot had been seasoned, it was found that out of 870 trees of sided timber, containing 611 loads of 50 cubic feet each, 239 trees, containing 169 loads, were defective. In Deptford, in October, November, and December, 1803, out of 138 trees, containing 114 loads, 74 trees, containing 60 loads, were found defective. Again, in Deptford, in April, May, and June, 1805, out of 230 trees, containing 268 loads, 65 trees, containing 99 loads, were found defective. And in Plymouth yard, on January 20, 1806, 636 trees, containing 990 loads, were found to be defective. It may be safely asserted, that at least one-third of the sided trees which are put past to season in the navy dock-yards become unfit for the building of ships in the course of three years. The national loss in this item of public expenditure must therefore be considerable, especially when we bear in mind that a first rate man-of war of 120 guns requires 5880 loads of timber to build her; a 74, 3600 loads, and a 28 gun frigate 963 loads. Now, Kyan's process as well seasons timber in a short time, as preserves it when seasoned, from dry-rot, as will be seen from this testimony of Mr. George Ward, Dorset street, Salisbury square, London, joiner, who cut a piece out of a log of Hispaniola mahogany, on 9th March, 1833, sent it to be steeped on 12th April, and used it in a wrythed hand-rail on 21st June of the same year. He cut another piece out of a log of the same kind of mahogany on 25th March, 1833, sent it to be steeped on the 4th June, and used it in a clampt flap and frame on 30th August of the same year. On 5th July, 1834, he says, "in neither of the above instances has there been the least shrinking of the wood since it has been used, nor has the color of the mahogny been at all injured by the process." It must be owned no severer trial for warping could unseasoned timber be subjected to, than in hand-railing and clampt-framing. We observe in this city that many cabinet-makers, rather than place their capital in a dormant state by storing up timber to be seasoned, send it to Kyan's tank to be steeped and seasoned just as they require it.

The ravages of the dry-rot among the ships of the navy are fearful. Independently of the enormous cost for repairs which this disease causes to be incurred to the nation, the jeopardy in which men's lives are placed at sea in ships in a state of dry-rot is worthy of the nation's consideration. It is not uncustomary for vessels to cruise on foreign stations for three years, and yet many of the ships of the navy have been obliged to be docked for repairs in a shorter time than that after they have been prepared for sea. Out of 23 seventy-fours, only nine exceeded three years before they were obliged to be docked for repairs after being built. The Ajax, seventy-four, was only five months at sea after being finished in 1798. The l'Achille, one year five months; and six others not exceeding two years. The Kent was longest in being docked, being seven years one month at sea. The average of the whole number did not exceed three years five months. But it is not the loss of service alone of such valuable ships when in dock that is most to be deplored, the pecuniary loss arising from repairs, entirely occasioned by the ravages of the dry-rot, is of greater importance. The hull of the Ajax cost in building £39,039, and after she had only been five months at sea, the repairs for dry-rot cost 26,683*l.* The six ships that had only served two years at sea cost in building their hulls in 1810, 1811, 1812, and 1813, £349,974, and afterwards in repairs for dry-rot £297,368. Eighteen frigates, rating from twenty-four to thirty-six guns, cost in repairs in 1805, £253,148 17*s.* 5*d.* and if they had been built anew, would only have cost £150,208 15*s.*, being in the proportion of three for building, and five for repairs. But the case of the Victory we shall particularize as a ship that can never cease to excite public interest The building of a 120 gun ship during the war, according to Edye's calculations, costs £97,400. In the very first year, 1800, the Victory, 100 guns, was repaired in Chatham, and her repairs did not terminate until 1803, until after they had cost £96,020. This was before the battle of Trafalgar in 1805. But in 1814, 1815, and 1816, she was again repaired at Portsmouth at the cost of £47,558. So that she has altogether cost for repairs £143,578 in fifteen years. But all these are isolated instances. The total sum for repairs for the whole navy cut a conspicuous figure. From 1800 to 1820, over and above the ordinary repairs of wear and tear, which were £6,412,592, the repairs cost £11,037,188, being an annual average of £551,859. The greater part of this period was in the time of war, but even in time of peace the dry-rot appears to have made as great ravages; for from 1822 to 1832 the cost for all repairs amounted to £7,971,852: 7: 4, being an annual average of nearly £800,000, which was about the war average. As the usual wear and tear should be much greater in war than in peace, it follows that the dry-rot is committing greater ravages now than in the war. That beautiful ship the Vernon, 56, has been siezed with this hurtful disease, and must, of course, go into dock at an enormous cost for repairs.

These facts call loudly for the adoption of some means for the prevention of so raging a malady. Many expedients, we believe, have been attempted by the Admiralty to assuage the evil, and tests have been used to ascertain the soundness of timber by immersing it in fungus-pits, but all have failed. Now, however, that Kyan's process has been proved to be efficacious in preventing this dire disease, the Admiralty ought to make a trial at least of one ship so prepared. Much money would no doubt be saved to the public by its adoption. What with extraordinary repairs, and building and ordinary repairs, the annual expenditure for timber in the navy-docks during the war was about two millions, one half of which might have been saved by the adoption of this process. But besides the prevention of dry-rot in ships, the stock of timber kept for seasoning may be dispensed with, besides the saving in repair of public works, such as docks, buildings, &c.

Important as Kyan's discovery is, in a national point of view, in regard to the navy, it is also important, in a national view, to the landed interest. If by this process proprietors of wooded estates can not only use the timber they grow in buildings, fences, implements, and for all country purposes; but dispose of it to others who have no wood fit for use, a stimulus will be given to planting which will soon clothe the waste places of the country with growing timber, and in time render the agricultural interest entirely independent of foreign timber. Indeed, it is proper to be prepared for such an event, for the settlement of the Canadas by emigration will in time so denude them of their magnificent forests, that no timber will then be available for exportation to this country. The value of this process is not confined to hard timber, it seasons sap-wood in as short a time, and preserves it also from decay. This property of it will have the effect of increasing largely the quantity of useful timber, if a tree, for instance, which may be squared to thirteen inches of heart timber, can be squared to sixteen inches including the sap-wood, its value as a marketable commodity will, by this process, be greatly enhanced; much timber being thus rendered serviceable, which would otherwise be wasted. The applicability of home timber to every purpose of building, fencing, and implements, would insure a great saving to the landed interest. That this process renders wood for any species of work durable, may be shown from the testimony of many credible witnesses. Two pieces of the same wood and from the same part of the wood, the one prepared the other not, were put into a pit in Wesminster where a great deal of rotting was going on; that piece which had undergone no preparation became pulverulent and crumbled down under the pressure of the fingers, the other, both being sap-wood, became like heart-wood, and manifested no tendency to crumble, though it had been cut with a knife. Captain Alderson, of the Royal Engineers, made some experiments in the Royal Carriage Office, Woolwich, to ascertain the effect of the process upon timber used in the construction of gun-carriages. He obtained pieces of oak, ash, and elm, quite green, with the bark on and twigs with leaves upon them. Half of the pieces were steeped in the solution, and the whole of them put into the fungus pit to rot in March 1835. They were taken out in September 1836, when the unprepared were quite rotten, and the other, even to the preservation of the bark, sap-wood, and leaves, were perfectly sound. The spokes, felloes, and shafts of carts and carriages could thus be rendered durable for an indefinite length of time. Sir Robert Smirke put a couple of posts under a dropping eave, and both were exposed to the same actions. After a certain time the unprepared decayed, the other still stands. He also put up a considerable quantity of paling about three years before he gave his evidence on this subject before the committee of the House of Commons, when it was in quite as good a state as at first, though it was partly in the ground; whereas, some paling which he had put up the year before, not fixed into the ground, but close upon it, unsteeped, was obliged to have its lower part cut away in three years. The fencing of plantations, young hedges, and the preservation of hurdles, field gates, watering troughs, thus may be almost permanently insured.

The sleepers used for railways may be used by this process with advantage instead of stone, and to all who have ever travelled on a railway laid on wood, it is obviously a much pleasanter motion than on stone. Now that the rage for railways prevails, the supply of timber in any part of the country through which the railway passes, will render its construction more economical. Pieces of green larch were used as sleepers on the Southampton railway; some of them having cracks wide enough to admit a penny piece. After being steeped they became compact, and the cut diameter which had been flat became curved, and the pieces more fit for the purpose they were intended.

The yearly destruction of poles in the hop grounds in England is very considerable. They have to be renewed every six years, besides being repaired every year. When steeped they will last thirty years, barring breakage. The annual expense of maintaining and repairing these poles is estimated at £10 an acre, so that by using this process the hop grower might supply himself with poles at one-fifth of the present cost.

It is equally efficacious in preserving flooring. Messrs. Harris and Warner, hatters, Southwark London, laid a piece of flooring partly prepared. In three years the unprepared part entirely gave way, whilst the other remained as fresh as the day it was laid down.

The process is a protection against the attacks of insects, both terrene and aquatic. A naturalist who has long been in the habit of collecting insects on old rails, cannot now find them lodged on any that have been subjected to the process. The piles used in jetties and dock gates, are effectually protected from the attacks of marine animals. We have seen two pieces of elm which had been cut out of the same log, and placed under water at the Trinity Chain Pier near Newhaven; after being a twelvemonth immersed, they were both taken up covered with young muscles. The prepared was quite fresh and sharp at the angles, whilst the other was decayed or rather eaten away at the angles and ends.

The commercial navy have taken advantage of the process. The ships Enderby and John Palmer of London were built of prepared timber, and both are South Sea Whalers. The Enderby sailed from London on 11th October 1834, and returned to Gravesend on 7th March 1837, having been absent twenty-nine months. She fished about the Equator, and although much subjected to a tropical and vertical sun, her seams remained entire. The John Palmer was away for three years and a-half, and came home equally tight. The bilge water in both cases was much sweeter and freer from noxious effluvia than usual. Apprehension was expressed about the healthiness of the crew of a ship that had been built of timber prepared in mercury. A similar dread prevented Sir H. Davy and Professor Faraday urging the employment of corrosive sublimate as a means of preventing the ravages of the book-worm in Earl Spenser's library at Althorp. These apprehensions may have arisen from a recollection of the well-known circumstance of violent and even fatal salivation affecting the sailors on board H. M. S. Triumph in 1810, from the rupture of bladders of quicksilver, and the escape of it about the ship. But they may all be dissipated by the testimony of Captain Lisle of the Enderby, who declares no crew could have been more healthy than his was all the time she was at sea.

But the process has the power of preserving cordage and canvass as well as timber. Colonel Sir John May, Inspector of the Royal Carriage Department at Woolwich, subjected to the same trial pieces of prepared cordage of five inches, with a duplicate piece of white unprepared cordage, also of two and a-half inches, one and a quarter inch, and pieces of tent line. The prepared pieces were quite sound, the unprepared quite rotten. Cart ropes, reins, and sheep nets may thus be preserved in use a long time. Sir John also subjected four pieces of canvass prepared which were not at all affected with mildew, whereas those pieces unprepared were affected, and one became quite rotten. Captain Farquharson of the Lord Hungerford of London, on his return from a voyage to the East Indies in June 1836, found an awning of canvass which was unprepared quite mildewed, whereas one of the same kind of cloth prepared was perfectly sound and clean. Thus barn sheets, cart covers, sacks, and windmill sails may be preserved from destruction by this process.

What need of adducing more evidence on the efficacy of this process for preserving animal and vegetable fibre? Let us rather investigate the principle of the process and recommend the adoption of it to those who have hitherto neglected to take advantage of its utility. Dry-rot in timber is frequently distinguished by a sort of mildew which covers it, and the action of which in time causes decay, or it assumes a less organized appearance and crumbles down into powder. This mildew is not the dry-rot, nor the cause of it, but rather its effect. It may be distinctly seen by the microscope to be a fungus, and springing up where it does, it becomes a question whence its germs can have found access into the wood. To assist in answering this natural query, we may state that Mr. Bauer, when treating of the pepper-brand, *Uredo fœtida*, states that fungus to be of a globular form and of the size of only $\frac{1}{1600}$ part of an inch in diameter, and therefore no less than 2,560,000 would be required to cover a square inch. The germs of such plants must therefore be infinitely minute. Professor Ehrenberg, also, when treating of the Monas and others of the Infusoriæ, states, that in the twelfth part of an inch there are 28,000, and in a square inch not less than 500,000,000. It is, therefore, extremely probable minute vegetable germs may be introduced through the spongioles of the roots of plants. Indeed Unger detected the existence of such bodies in the stem of *Galium Mollugo*, which he has termed the *Protomyces endogenus*, developed in the coagulated juice of the intercellular spaces. All plants, as is known, are composed of cellular tissues, whether in the bark, albumen, or wood. The tissue consists of various shaped cells, and although no single cell may pass along the whole length of the plant, as M. de Candolle maintains, yet there is no doubt water, air, or even mercury, can be made to pass through those cells in the longitudinal direction of the fibres of wood. Experiments with the air-pump have proved this passage beyond doubt. These cells contain the sap of the plant, particularly those of the alburnum, and in the circulation of the sap through the tree its watery particles fly off by the leaves, and the albumen remains. Albumen is the nearest approach in vegetables to animal matter, and is therefore, when deprived of vitality, very liable to decomposition, particularly when in the alburnum or sap-wood. On minutely inspecting wood going to decay, Mr. Kyan was impressed with the conviction that decomposition of the sap in the alburnum gave rise either to the dry-rot, or, by the evolution of heat, vivified the germs of the fungi that may have been lying dormant in the cells of the alburnum. Now, as corrosive sublimate was known to preserve animal matter from decomposition, so might it preserve albumen. The experiments which he performed on albuminous and saccharine solutions with corrosive-sublimate, confirmed the correctness of his conjectures. But the prior experiments of Fourcroy, and especially of Berzelius, in 1813, had produced the same chemical results, although the latter had not discovered their practical applicability to preserving wood. Berzelius found the addition of *bi-chloride* of mercury to an albuminous solution to produce a *proto-chloride*, (calomel), and the proto-chloride combined with the albumen, and produced an insoluble precipitate. The insoluble precipitate hardens like a fibre, and fills up the open cells. This is the chemical principle of the process. The intention of seasoning timber by exposure to the air, is to dry up the albumen before it begins to decompose naturally; but that the seasoning is not always successful, may be ascertained from the defective state, already alluded to, of so large a proportion of the timber in the naval dock-yards. We may now see how green wood may be seasoned at once by the process, in that there is a larger proportion in it of albumen for the sublimate to act upon. The process is somewhat analogous to tanning leather, the tannin principle of the bark combining with the animal jelly of the skins, and forming an insoluble precipitate. Oak contains much of the tannin principle; and, as the sublimate does not act upon it, oak, of all woods, least changes the sublimate solution. The process thus resting on simple chemical bases, its efficacy can never be neutralized. Nor can deception be practised by those who intend to deceive the unwary. A chemical re-agent exists, by which the wood can be tested that has been properly steeped. A drop of hydrosulphuret of ammonia will make a black mark on wood steeped in corrosive sublimate, whereas it will produce no change on common timber.

We are glad to be informed that thirty-five tanks of Kyan's solution have been erected by noblemen and gentlemen in Scotland, upwards of sixty in England, and a few in Ireland, for the purpose of serving their own estates. Tanks are now to be found in all the principal maritime ports in the kingdom. Ship-wrights and joiners do not relish the process, in the apprehension their services may be less required, but owners of ships and proprietors of houses will, nevertheless, use it for their own sakes; and we have no doubt, ere long, shipwrights and builders will be unable to dispose of new ships and houses, unless they have been constructed of timber subjected to the process.

With regard to the expense of the process, which is a material consideration to those who use large quantities of timber, a builder, whether of ships or houses, pays for steeping *one pound* sterling per load of fifty cubic feet. Gentlemen taking out private licenses for their own estates, and not for the purposes of trade, pay *five shillings* per cubic foot of the internal area of the tank erected, for the use of the invention during the whole term of the patent. Licenses for trade are given on the principle of receiving a small *pro rata* proportion of the profits of the license. Exclusive licenses in towns are only granted to those who qualify as shareholders, in order to secure their zeal for promoting the interests of the company.

SASSAFRAS. RAT-PROOF MEAT-HOUSES. CLOSE-GRAZING. HILL-SIDE DITCHES.

To the Editor of the Farmers' Register.

Waterloo, N. C., March 26th, 1838.

In a former number of the Register, I suggested the idea of boring into sassafras trees, and pouring into the opening thus made, some liquid substances, which might, by being carried with the sap into every part of the tree and roots, destroy their vitality so as entirely to rid us of that most troublesome nuisance. By way of beginning the experiment in the latter part of the last summer, I bored into a sassafras tree of about five inches diameter with a half-inch auger, and poured in about a table-spoonful of sulphuric acid. Within two or three days, the leaves on about one-half of the tree began to turn of a reddish brown color, and by the fourth or fifth day, were black and dry. The body and branches likewise of about half the tree, put on the appearance of dead half-seasoned wood, as appeared from incisions made with a knife, whilst the remaining half of body, branches and leaves, preserved the appearance of other adjacent trees of the same sort. This state of things continued until frost, when the leaves on the living part of the tree faded and fell; those on the dead part, remained until lately. No farther examination was made until recently. The whole tree now appears to be dead. I will watch it, and inform you whether the tree dies or not, and whether any sprouts spring up from the roots. This may appear a small matter to be made the subject of a communication for the Farmers' Register; yet I am sure there are many, very many by whom any practicable and cheap means of destroying the sassafras, will be joyfully and thankfully received.

Having noticed several plans recommended in the Register for rendering meat-houses rat-proof, and believing one which I have adopted greatly preferable on the score of both economy and effect, I will in a very few words describe it, pledging myself that it will prove effectual, wherever properly executed. Have your house built in the ordinary way of framed buildings, leaving no opening large enough to admit rats through the body, roof or door. Fill up the floor to the depth of twelve inches or more with common quartz stone, or as it is called in our country dialect, white flint rock, and pound them with a stone-mason's hammer until they become of the proper degree of fineness, and lie close enough to prevent a mouse from finding an opening in them large enough to hide himself.

I was greatly surprised upon the receipt of the last No. of the Register, to find a highly intelligent correspondent of yours, maintaining the position, that "*constant, and even heavy grazing, does not of necessity impoverish land.*" I had previously thought, that if there was unanimity of opinion amongst farmers on any subject that admitted a variance, it was in relation to grazing. I think your correspondent has been as unfortunate in his arguments to sustain his position, as he has been in assuming the position itself. He says the commons in the vicinity of towns, &c. grow rich in consequence of heavy grazing. As well might he have said, that our summer cow-pens are enriched by close grazing, or that his taking money out his own chest, was the reason it was becoming daily fuller and fuller. In all three cases, the true cause of improvement may be found in the fact, that the *addita* greatly exceed the *abstracta*. I am theoretically and practically a grazier myself, and keep a large stock; but the idea of improving land by mere grazing, is one that I had never dreamed of. I am improving my own land, not *by* grazing, but *in spite of it*.

In relation to hill-side ditching, which I believe contributes more to the value of land than any other improvement which can possibly be made at the same expense, your correspondent alluded to above, is in my opinion much more fortunate. He thinks the ditches have not usually sufficient fall. I think the fall ought to be three times as much as it usually is. Those which I have made have at least double as much as any I have ever seen; yet I intend to give those I may make in future, still more. The more fall they have, the less is the necessity of having them wide or deep, and of course the less labor is required to make them. Should they exhibit a disposition to wash too deep, a few stones, blocks of wood, brush, or almost any thing not light enough to be carried off by the water thrown into the ditches, in heaps about a hundred yards apart, will effectually prevent farther washing. As far as my observation extends, I have seen many fill up, but not one wash into a gully. W. O. GREGORY.

ADVANTAGES OF PLANTING CORN EARLY, AND COVERING THE SEED DEEPLY.

To the Editor of the Farmers' Register.

Watkinsville, Clarke County, Ga.

Nearly a year ago, I received by mail a number of the Farmers' Register. An African king once inquired if his name made much noise in Europe. With something of this self-importance, I supposed you had somehow heard of my love for agriculture, and all things connected with it, and had done me the favor to put me down as a subscriber. I was much pleased with the number sent, and expected to continue to receive them; but as no more came, I read over the one I had the oftener. The cause of no more coming, I never knew till a few days ago. I was showing some of my little ones how to paint a copy of the farm-house on the first page of the cover, and happened to notice, for the first time, that you had written that this number was a present. For this civility receive my best Sunday thanks; but truly, I regret it was so nearly rubbed out that I never noticed it before; for I have lost many hours of pleasant amusement for want of the other numbers. I now send you ten dollars. I cannot consent to lose so much of a good thing; so I want you to send me the back numbers for the last volume, as well as the current volume. And now I will send you some lines to read; perhaps you may not think them of any value; if so, the fire will soon put them out of the way.

It is a very common opinion, that early planted corn should be covered very shallow. It would be difficult to calculate the annual loss that this error causes. In our state, very early corn will generally produce fully one-third more than late corn. Late corn is generally between two and three feet taller than very early corn; the ear is always higher on the stalk; and whoever will take the trouble to plant rows of corn, late and early, by side of each other, will find the late ears fully one-third smaller than the early. Again—late corn is always more injured by worms, moles, birds, &c.; it requires much more replanting; and the replanted corn makes very little, often nothing. Early planted corn always makes a better stand, and the replanted makes good corn. Early corn is made before the longest and hottest days come, and before the dry weather sets in; consequently, it will bear being much thicker, without firing (burning). In planting a crop, we can get such a forward start, that much more ground can be tended. Corn manured with unrotted manure, more especially, should be planted very forward; for, when planted late, if a drought comes on it, the manure often does more harm than good, as it is so apt to burn up the corn. The result of my experience, and I speak practically on it, amounts to about this: that corn planted the first of March, generally produces one-third more, and with one working less, than corn planted the first of May. Let whoever doubts this, take the trouble to plant a field in alternate rows, giving two months between the times of planting; or plant one acre very forward, and another acre, by the side of it, very late; and I am satisfied he will decide with me. In fact, by rough measurement, I have made the difference greater than what I have named. When I speak of forward corn, I want some data to go by, so that my meaning may be understood. I will try to explain myself, by stating that, in my neighborhood, corn planted the last week in March and first week in April, is considered forward; when I speak of planting forward, I mean the last week in February and first week in March.

And now with respect to the covering. Whoever plants corn very forward, and covers shallow, will regret it; for he will have a poor stand of weakly looking corn. The common opinion is, that shallow corn is acted upon and warmed by the sun, which causes it to sprout; will not a little reflection convince any person, that if the sun does cause it to sprout, that the ground when it freezes as deep as the corn, (which it will do every hard frost,) would kill the roots of the corn, and if not killed, be so much sickened, that its recovery would be slow? This will explain why early corn, covered shallow, is so apt to be killed by frost, if it does not sprout. But experience fully decides, that when shallow-covered, if the sun warms it in the day, the frost chills it at night; and most of it rots, without ever sprouting; but cover the corn deep, very deep, and it will come up prime. If the frost *does* bite, no injury is done; and we insure the best kind of a stand. This I know by experience to be correct. My corn has been several times covered deep with snow; and yet the more forward the corn, the better the stand, and the better the crop. But let us reason on it. Why is spring-water warm in the coldest weather, but because the earth is warmer as we go deeper, and colder as we approach its surface? This fact is fully established by making holes of different depths, and testing the temperature with a thermometer. In cold weather, make a hole in the ground, and put the hand in it, and it will be found warm. The fact that the earth is warmer in winter a foot deep, than it is an inch deep, every body knows; and it must follow, as a matter of course, the deeper we cover corn in reason, the warmer and more uniform its temperature would be. This I say; first cover with hoes, then list on it, covering it still deeper, and it will be so warm and kept of so uniform a temperature that it will not rot, and will sprout much sooner than shallow-covered corn. Again: forward corn is apt to be nipped by late frost. If the corn is covered deep, the frost only bites the top; and I have never been able to see that it injured it in the least; cover some plants so that the frost cannot bite them, and in a few days we will see no difference in what was bit by frost, and what was protected. But where the corn is planted shallow, the ground freezes to the root, and kills it. Whoever will examine, will find that late frost extends a very little way down. It is only a thin shell, as it were, that extends deep enough to kill shallow-covered corn, but does no injury to corn which is covered very deep.

Against this early planting, some argue that nature is a correct guide, if we would observe and follow her; and that corn should not be planted till the trees show young leaves, and weeds, grass, &c. begin to show themselves. When we see the young peaches killed by frosts more than one year in two, and often the leaves in the woods all killed by frost, it certainly gives reason to think that nature is not a sure guide as to the time of planting. But in reality, if we would follow nature close, she would give us much better directions. It should be considered that the trees are, as it were, planted all winter, and all the seeds of weeds, &c. have been planted all winter; and that we should not consider the time they begin to vegetate the proper time for planting. They required a time of preparation, and corn should be planted several weeks before, that the corn may also have this time of preparation in the ground.

All practical planters know that late corn should be covered deep. Every body knows that when covered shallow, if a dry spell happens, the ground becomes so dry that the seed is very long coming up, and then comes up very irregularly; that it is much more injured by birds, squirrels, worms, &c. than when covered deep. The result is a thin stand of irregular corn, and late corn replanted makes very little, every practical planter knows by experience; for the difference is very perceptible, that late corn should be planted deep to make good corn. This is a fact so plain, that it is a common maxim with practical planters; but the very common theory to explain the fact, is wild and altogether erroneous. They say, as the corn is late, plant it deep that the roots may be deep, to contend with the long dry hot days which are to come. When corn is planted, cover it deep or shallow, the seed sends out the sprout and its roots; the seed and these roots nourish the plant till it grows perhaps four inches high. It then sends out a circle of horizontal roots, just under the surface; and as soon as these roots are sufficiently extended to nourish the plant, all below them dies; so that whether the seed is one inch or six inches deep, by the time the plant is six inches high, the roots are of the same depth, and wholly unconnected with the seed, and all the first roots that came from it. I once pulled up some stalks of corn, and showed an old planter that all below these horizontal roots died as soon as they were extended a little in the ground; he said he was obliged to confess that he had always reasoned wrong respecting the roots of deep-covered corn being deeper than shallow-covered corn; but said he cared not for reasons; he knew the fact from the experience of a long life, that the later corn was planted, the deeper it should be covered. If this is fact, which all will admit, that late corn covered deep will produce much more corn than shallow-planted; and this is fact, which every one can satisfy himself of by pulling up a stalk of corn six inches high, that it does send out this circle of horizontal roots just under the surface, and all below them dies immediately. Why is deep-planted corn better for a large crop than shallow-planted, but because we thereby have a more forward start and a better stand?

ROBERT R. HARDEN.

April 13, 1838.

THE MARL DEPOSITE OF SOUTH CAROLINA.

To the Editor of the Farmers' Register.

Bristol, Pa. February 27th, 1838.

* * * * *

In your last number, I observed that until recently, you did not appear to have been well apprised of the existence of shell marls in South Carolina. The localities are very numerous; amongst the most noted, at the time I resided in that state, were Santee Canal, Eutaw Springs, Dr. Jamieson's, near Orangeburg court house, Mr. Darby's, St. Matthew's parish, Godfrey's ferry, on Pedee river, Givham's ferry, on the Edisto, &c. &c. They form a part of the great bed of tertiary deposits, which extends from New York through the whole of the Atlantic states, south Florida, Alabama, &c. on the Gulf—not always perceptible at the surface, from a covering of more recent products.

LARDNER VANUXEM.

[We were not unacquainted with the general geological fact, that the great deposite of fossil-shells, or marl, extends through South Carolina. But, until recently, we had been entirely uninformed as to the bed being visible, or easily accessible, in any particular localities, or of the facilities offered by its position and richness, for its being used profitably as manure. Judging from the contents of both the articles from which we derived such information, the existence of this richest treasure of South Carolina, is yet as little known in that state, as its value is appreciated. We earnestly hope that this strange degree of neglect and inertness will not long continue.

Mr. Vanuxem is one of those now charged with making the geological survey of New York.—ED. F. R.

From the New York Farmer.

MELONS GROWN OVER WATER.

At the last meeting of the Horticultural Society, amongst the fruit from the gardens were two melons, grown over water, into which the roots descend, a plan by which it was found that this fruit would arrive at earlier if not at better maturity.

ON THE BENEFIT OF USING STRAW AS TOP-DRESSING FOR YOUNG CLOVER.

To the Editor of the Farmers' Register.

Madison, April 14th, 1838.

As the time is near at which farmers generally haul out the straw which the farm produces, beyond what is requisite for the support of its stock, I take the liberty of recommending the appropriation of some of it to an object worthy of their attention, but which hitherto seems to have been entirely neglected; that is, as a top-dressing to wheat, for the purpose of ensuring clover on spots which otherwise would be entirely destitute of vegetation. The first numbers of the Register contained several articles on the subject of scattering straw, which attracted my attention, and for some years I followed the course there recommended; that is, to haul out the surplus straw as back loads, when bringing in the crop of wheat to the machine, and then at some convenient time to spread it. This method has its advantage, as it is hauled out with little or no loss of labor; but here it ends, and the disadvantages begin; for this was never as valuable as the one which I pursue, and for this simple reason, that the poor spots on which it had been spread, had failed to take in clover; and then, instead of the heavy growth of clover which it can produce, we had to depend on the modicum of straw which we had applied for the improvement. My course is now, to apply the straw immediately after sowing clover seed, and the result has exceeded my most sanguine expectations; for at this time, I have clover on poor spots thus treated, much better than on land much richer; and it is now better than it would have been for years to come, had it been left as such spots generally are. It may be said that fine manure would be better, as by that, not only the clover, but the wheat would be improved by it. I admit the truth of this, provided it could be done; but when we reflect on the labor requisite to accomplish top-dressing on as large a scale as the impoverished condition of Virginia requires, it seems out of the question even to hope that, as a general thing, it will ever be accomplished. In recommending the above course, I go upon the idea, that in agriculture, as in government, we should be content with the most practicable scheme, and leave to others the pursuit of theories as beautiful as they are difficult; and furthermore, I shall be content to have this tried as an auxiliary, for one trial will suffice to fix our attention to it; for when we take into consideration the facility with which straw is moved, and the surface over which a load will extend, I hazard little in saying, that there is no way in which as much improvement can be effected; and furthermore, I contend, that even admitting that our lands have strength enough to ensure clover, we should find our account in this application, as it is in the infancy of the clover that it gives an impulse which no application, made at a later period of its growth, can give.

AGRICOLA.

P. S. If farther proof of the excessive drought of 1837 is necessary, permit me to mention a fact which came under my observation about the middle of March. I had a ditch cut through a portion of my low grounds, and I found that the clay, at the distance of three or four feet under ground, was completely dry, so much so indeed, that as it was thrown out, it could be converted into dust without difficulty. What makes it more remarkable is, that an entire winter's snow and rain had not been adequate to its correction.

SOUTHERN COMMERCIAL CONVENTION.

[We request attention to the following able report upon a subject of vital importance to all the southern states. Having in the preceding volume, (p. 506,) when presenting the proceedings of the first meeting of the convention, expressed our sentiments fully and clearly in favor of the general objects in view, it is unnecessary to offer further comment on that score, at this time.

The wretched and deplorable state of the currency and of exchange, though one of the sorest evils ever inflicted on our country by mis-government, will be compensated to the suffering south, if this state of things should continue long enough to produce the effect to which it manifestly tends, of discouraging the continuance of the artificial system of the southern states trading with Europe through New-York, and paying to northern merchants, as agents and "middlemen," a profit on every sale and every purchase, made on account of southern producers and consumers. One of the advantages of a paper currency which is most frequently referred to by its most thorough-going advocates is its furnishing means for the easiest and cheapest possible transmission of funds between distant places. Now, it costs an addition of at least five per cent., for exchange, for a debtor in Virginia to pay his creditor in New-York, or for a cash purchaser to obtain goods there. In other words, it costs five dollars expense to convey from Virginia to New York 100 paper dollars; and from thrice to five times as much, from some other places. Yet there is no question, with any one, but that the bank notes of Virginia, on which 5 per cent. must be lost in New-York, are just as good as those of New-York, which command that premium in exchange; or *just as bad*—(to reverse the proposition—) the banks of both being alike able, and yet both alike refusing, to perform the false promises to pay, which are displayed on the face of every one of their notes.

If we had a currency as cumbrous and heavy as silver, it would cost but one half of one per cent. to convey it across the Atlantic; and even if it were in copper, it would not cost so much to transfer it to New York, as it now costs in the *lightest* currency in the world. But to return to our position. The effect of this enormous difference of exchange, is to compel the merchant from Virginia, or North Carolina, who now buys foreign goods (as heretofore) in New York, to pay 5 per cent. more than the price and all other previous charges; and of course so much more than he would have paid to the direct importing merchant at, or nearer home. This additional 5 per cent. is too heavy a deduction for ordinary profits to be long borne, and it operates as so much additional inducement to carry on a direct foreign trade between the reciprocal consumers and producers. Reason would sufficiently show this to be the tendency, and ultimate effect, of the higher price of the inconvertible bank notes of New-York over the inconvertible bank notes of the south; but facts also have proved that the effect is now in progress. The few importers of Virginia have sold out their stocks of newly imported goods, at good profit; and so rapidly, that some of the country merchants who stopped to buy, in preference to paying the additional northern tax in exchange, could not be supplied. Now is the time for Virginia and the more southern states to throw off the yoke of commercial bondage.—Ed. Far. Reg.

Report of the Committee of thirty-one to the Merchants' Convention, presented on Wednesday of the session of that body, by Gen. Robert Y. Hayne.

The committee of thirty-one, who were instructed "to consider and report on the measures proper to be adopted by this Convention," beg leave respectfully to report:

That they have bestowed upon the subject referred to them, the attention which its importance demands. Time does not permit, nor does the occasion perhaps require, an elaborate examination of the subject in all its bearings, and this is the less necessary, as the able documents recently published by the convention, have exhibited in the clearest light, and demonstrated in the most conclusive manner, every point which it could be important for us to establish. Indeed the whole question is embraced in the single proposition, that it is the interest and duty of the slave-holding states of this Union, to improve their natural advantages, by securing to themselves that portion of the commerce of the country which rightfully belongs to them; a proposition which, if it be not self-evident, cannot derive much support from argument or illustration. We rest our whole case upon the fact, which is beyond all dispute, that the southern and south-western states furnish three-fourths of the entire domestic exports of the whole Union, while they import but little more than one-tenth of the productions received from abroad in exchange for these exports. It has been shown in the documents published by the convention, that when the imports of the United States amounted to $190,000,000, those of all the Atlantic states south of the Potomac and the states on the Gulf of Mexico, amounted to only $20,000,000; and while the domestic exports of the Union amounted to $107,000,000, the states of the south and south-west exported $78,000,000.

South Carolina and Georgia, while furnishing exports to the extent of $24,000,000, actually imported less than three millions and a half. The amounts have varied in different years; but this may be taken as an exemplification of the condition of southern trade.

The mere statement of these facts, must surely convince any unprejudiced mind, that this unnatural state of affairs could only have been brought about, by the most powerful and extraordinary causes, and that from the very nature of things, the effect must have been highly injurious to the southern states. Without attempting to trace all the causes which have had an agency in producing this result, we will merely advert to one of the most obvious, and which is perhaps sufficient of itself to account for it; we allude to the UNEQUAL ACTION OF THE FEDERAL GOVERNMENT, especially in the mode of LEVYING and DISBURSING THE PUBLIC REVENUES. If, instead of throwing nearly the whole of the public burdens, in the shape of duties, upon those foreign goods which are received almost exclusively in exchange for the great staples of the south, the revenue had been levied in a direct tax (however largely exceeding the wants of the Government,) the burden would have fallen, at least, equally upon the different portions of the Union. But by the system which was adopted, while the labor and capital of the south was borne down by a weight of taxation, which in many instances, amounted to one half of the whole cost of the articles received in exchange for their productions, the labor and capital of other portions of the Union were substantially exempt from taxation, and even stimulated by enormous bounties. Nor did the evil stop here. Under the pretext of encouraging "domestic industry," duties on foreign goods were imposed to an amount *greatly exceeding the wants of the government*. The amounts thus brought into the treasury were *accumulated in the northern cities*, and especially in New York, from whence they were drawn only to be distributed among the military and naval establishments at the North; the surplus being finally divided among pensioners, and internal improvements in the same quarter, and in the west. Hundreds of millions of dollars were thus drawn from the south, and expended north of the Potomac; and our wealth was conveyed from us by a steady stream, constantly flowing northward, in a current as undeviating and irresistible as the Gulf stream itself, which "knows no reflux." With this system, other influences were combined, all having the same object in view, and tending to produce the same general result. On these, time does not permit us to dwell. It is sufficient for us merely to mention the long credits—the auction system—the centralization of the exchanges; and the concentration of the whole patronage, power, and influence of the Government in favor of the north, and especially of the city of New York—causes of themselves abundantly sufficient to secure them those advantages against which we so long struggled in vain. The calamities under which the south labored, under the operation of this system, belong to that class which one of the ablest writers on political economy has declared to be worse than "barrenness of the soil and the inclemency of the heavens;" for if our fields were fertile and the heavens propitious, the harvest was for those, "who reaped where they had not sown." Under these circumstances, so far from its being a matter of surprise, it was the result almost of an evincible necessity, that the commerce of the south and south-west should be thrown into the hands of the northern merchants: that the exchanges should be centralized at New York; and that we should be rendered TRIBUTARY TO OUR NORTHERN BRETHREN. To show that we have not mistaken the character, or natural effect of the causes which we have mentioned, we will advert to one among many facts illustrative of the truth of our position. Before the introduction of the protecting duties, a large and profitable direct trade *was actually carried on* between the cities of the south and the ports of Europe, by southern merchants, and in southern ships. For several years prior to 1807, for instance, our imports into the city of Charleston, amounted to several millions of dollars annually. From this period, under the operation of the "restrictive system," they gradually dwindled down to less than half a million. From the period, however, when the American system received a fatal blow, and the government commenced retracing its steps, back to the free trade system, our imports began to increase, and have been steadily increasing ever since; thus showing, conclusively, the true sources of southern depression on the one hand, and of southern prosperity on the other. FREEDOM is the very element of the south, in which "she lives, and moves, and has her being." Freedom in "all the pursuits of industry," is essential to our well-being. We look back with surprise to the fact, that a people possessed of such vast advantages should have so long and so patiently submitted to a state almost of "colonial vassalage;" and we hesitate not to say, that the page in our history, which records the rise and progress of the "American system," (so called,) will be regarded hereafter as disreputable to the intelligence of the age, and to the public spirit and virtue of the American people. But, happily for our prosperity, and we will add, for the peace and harmony of the Union, this system has been broken down—we trust and believe *for ever;* and we are coming back, by slow but sure steps, to the great principles of FREE TRADE and UNRESTRICTED INDUSTRY.

To avail ourselves, however, of all the advantages of this great and salutary change in our system, it is indispensably necessary, that we should free ourselves from the trammels of long-established habits, opinions, and prejudices. It is one of the greatest evils of misgovernment, that the effects continue long after the evil itself has been corrected, and in all commercial operations, the influence of established usages, is extremely difficult to overcome. To divert capital from its accustomed channels, to introduce new associations and habits of business among commercial men, is one of the most difficult tasks which any people can impose upon themselves; and if it were not for the high spirit and intelligence of our people, we might distrust our success. When we survey the actual condition of the southern and south-western states, however, who can fail to perceive that we possess IMMENSE ADVANTAGES in this contest, which properly improved, must, in the end, crown our efforts with triumphant success. It is true we have but few ships, but we have ship timber in abundance, of the choicest description; and surely no southern man can be insensible of the importance of securing a mercantile marine, which in the future changes and chances to which our country must sooner or later be exposed, may be essential not only to our prosperity, but to our very existence as a free people. We want, also, it is said, commercial capital and credit, and cannot, it is supposed, furnish an extensive market for foreign goods, as will enable us to enter into successful competition with the cities of the north. Now, we base all our calculations and rest all our hopes upon the fact, that it is the *natural course of trade,* to exchange *directly,* the productions of one country for those of another; and that all indirect and circuitous modes of intercourse must be attended by increased expense, and be therefore less advantageous to all parties than the direct trade. Trade, like water, always seeks its level, and unless when opposed by natural or artificial barriers, will run its course in the *shortest and most direct line.* It must be admitted, therefore, that but for opposing obstacles, which have been interposed, and which have forced the commerce of the south *out of its natural channels,* our cotton, rice, and tobacco would have found their markets in Europe, by the shortest and most direct route from southern sea-ports and in southern ships; and it is equally obvious, that the foreign goods received in exchange for these productions would have been returned to us through the same channels. Now, can any plausible reason be assigned, why, under *a system of free trade,* the exports of South Carolina and Georgia—amounting as has been shown to $24,000,000 annually, should not be sent directly to Europe from Charleston and Savannah? and why the foreign goods *for which they are exchanged,* should not be imported directly in return? Our harbors are safe and commodious, the voyage is shorter and safer, and the freight less. But what is of infinitely more importance, we actually PRODUCE THE VERY ARTICLES which are to be exported, and require FOR OUR OWN CONSUMPTION the very goods to be received in exchange for those exports. Now, can any thing be conceived more unnatural—more out of the usual and proper course of business; than that OUR COTTON, which is to be exchanged for the manufactures of England, should be first shipped to New York—there sold to the New York merchant—by him transhipped and sent to England—there again sold and converted into British goods—which goods are to be first imported into New York, and from thence forwarded to Charleston—thence to be sold to the Carolina merchant, and paid for in bills at 6 per cent. Count the number of agencies employed in this transaction; sum up the freight, insurance, commissions, profits, and other charges; consider the loss of time and the risks incident to such a course; and can any reasonable man entertain a doubt, that if *such a trade* can be carried on at all, a DIRECT IMPORT AND EXPORT TRADE, (if there be no obstacle interposed,) must be infinitely more profitable? Under similar circumstances, the capital required to carry on the indirect trade must be much greater than that which must be needed in the direct trade. Indeed, under a system of mutual exchanges of our productions for those of Europe, the capital required, under a well ordered system of commercial arrangement, would be comparatively small. Credit might, to a great extent, supply the place of capital, and such a trade might be conducted on principles, which might ensure to the planter the largest profits on his crops, and his supplies at the lowest rates; while the merchant, the ship-owner, and every other class in the community, would participate largely in the advantages of such a trade.

But let this direct intercourse be once established, and capital would *soon flow in from all quarters,* to supply any deficiency that might be found to exist. The great law of demand and supply, would not leave us long without a money capital, fully adequate to all the operations of trade. So with regard to the market for the foreign goods, which under this system would be received at our southern sea-ports. Obtaining them, as we should be able to do, at less cost than they could possibly be procured through New York, we would unquestionably be able to dispose of them on advantageous terms, at least to the extent of *our own demand* for those goods; and this alone would increase our direct importations to five or six times their present amount. If only the consumption of the south was supplied through her own ports, this of itself would create a revolution in our trade, which would change the entire face of the country, and pour a flood of wealth and prosperity through every part of our land. But it is one of the most important and interesting features of our system, that it is inseparably connected with the extension of our intercourse with the interior of our country, by means of rail roads, canals, and turnpikes. A connexion between the south and the west by the various schemes now in progress in Virginia, North and South Carolina, Georgia, and Alabama, will furnish an outlet for all the goods that can be received from abroad in exchange for our productions. And when the great west shall find a market and receive her supplies through the sea-ports of the south, a demand will be furnished, the extent and value of which *cannot* be too largely estimated. Let these various schemes, therefore, for the extension of our interior connexions, be prosecuted with a zeal and energy worthy of the object. Let no unworthy jealousies—no narrow or merely sectional views, disturb that harmony of feeling and concert of action, which are so essential to success.

There are some circumstances connected with the present condition of the country, which may serve to animate our zeal, encourage our efforts, and urge us to that prompt action on which our success may depend.

Our great staple has now become *"the common currency of the world."* It is the great *medium of exchange*, regulating and controlling, to a considerable extent, the commercial operations both of Europe and America. During the suspension of specie payments, it affords almost the only means of obtaining *those credits abroad*, on which northern commerce has heretofore mainly relied for its support. This great staple is our own.

The revolutions which have recently taken place in the commercial world—the failures and destruction of credit in New York, and the stoppage of the American houses in Great Britain, has brought about a crisis peculiarly favorable to our views. Here is our cotton lying at our very doors; the produce of our own fields, and furnishing at this time, the only medium of exchange for the manufactures of Europe. Why should our own merchants not *use it* for this purpose? The door is now open to us, and we have but to enter and take possession of that which belongs to us. If we improve the opportunity, the victory will be ours. The tide in our affairs is at the flood. Let us launch upon it bravely, and it will assuredly "lead us on to fortune." But should this glorious opportunity be *lost*, our gallant bark, instead of riding the waves in triumph, may be driven among the breakers or dashed upon the rocks, or at best be again involved in those "eddies and shallows" from which we may never more be able to escape. Even the "Pilot who weathers the storm" may be compelled to "give up the ship," when deserted by the crew and left in a condition so utterly hopeless.

The *measures* which are deemed by the committee proper to be adopted, in order to carry these views into effect, are embodied in distinct propositions, which are herewith submitted to the convention. They embrace a strong and emphatic declaration of the feelings and opinions of the convention, on the importance of a direct import and export trade, and the duty of adopting all proper means for the purpose of establishing and promoting it. They recommend, in the next place, strong, earnest, and reiterated appeals, to the understanding and feeling of all the people interested, with a view to enlist their sympathies, excite their patriotism, and to call into action *an enlightened public opinion* in furtherance of our views. An adjourned meeting of the convention to be held in this place, on the 3d Monday in October next; an *address* to the people of the slave-holding states, and the adoption of other suitable measures to secure a full representation, at that convention, from *all the states interested*, are among the measures recommended. In looking to the essential objects of providing *capital* and *credit*, as well as markets for our imports, and thus laying a sure foundation for the ultimate success of our schemes, a series of important practical measures have been recommended, which if carried into full effect, will, it is confidently believed, go very far to put our merchants on a footing with those at the north. An earnest call is made upon the *banks*, to which they can hardly fail to respond, to provide the required capital and credit, by arrangements perfectly safe as to themselves, and at the same time well calculated to furnish all the facilities which the direct trade will require. A plan for *equalizing our domestic exchanges*, and keeping up the credit of our banks during the suspension of specie payments, has also been devised, which it is most earnestly desired may be carried into effect by them. It is not to be concealed, that without the aid and support of the banks, the difficulties in our way will be greatly multiplied. It will depend upon them, in a great measure, to determine the fate of our great enterprise. In order to divert capital and credit from other pursuits into the channels of commerce, an appeal is also made to planters, capitalists and others, to avail themselves of the provisions of the acts of the legislatures of the several states, passed during the last winter, authorizing *limited partnerships;* and it is recommended that the youth of our country should be directed to commercial pursuits, and prepared by a suitable education to fill the responsible station, and elevate the high character of the *southern merchant*. These, and other suggestions embraced in the resolutions, constitute the measures recommended to the convention for their adoption. It will be seen, that they embrace a series of measures of a practical character, all believed to be well calculated to promote the objects for which they are designed. It is true, that we can do no more than to urge the adoption of these measures on the part of the banks, and others interested. But when it is recollected that this convention is composed of near two hundred delegates, representing five states and one territory, and when we consider the weight of character, influence, and acknowledged talents of those who compose it; and when, above all, we remember that they are engaged in a matter of *deep public concern, involving the welfare, prosperity, and honor of these states*, it can hardly be believed, that their deliberate opinions and earnest recommendations can be without effect. Our chief dependence after all, however, must be upon *public opinion;* but we have too much confidence in the truth and justice of our cause to entertain a doubt of our success, if every member of this assembly would regard it as his *own personal concern*; as well as a sacred duty which he owes to himself, his posterity and his country; to use his utmost efforts to advance the great work. Judging from the past, we have no cause to distrust the future. Six months ago the first meeting of the convention took place at Augusta. It was composed of 80 members representing two states and one territory. Now we have five states and one territory represented by 180 members. The proceedings of the assembly have gone abroad, and wherever they have been received, have produced a powerful influence on public opinion, of which we have the most gratifying evidence in the legislation of several states on one of their recommendations, and the increased interest every where felt in the subject of their deliberations.

Thus encouraged, we should go on in that confidence, which a good cause should never fail to inspire. But to secure success, we must be prepared to make the necessary efforts. Of one thing we may be assured, that this great victory cannot be easily achieved. It is the order of a wise and benificent providence, that nothing truly great or good, can be attained without pains and labor.

This is the price which must be paid to secure success; and if we are not prepared to make the necessary exertions, we must yield the prize. Nor can our mighty work be accomplished in *a day*. All essential changes in the condition of a country, must be worked out by slow degrees. We may be assured, that nothing short of a high resolve, which no opposition can move, a devoted zeal, proof against all discouragements, and an untiring perseverance, which shall rise superior to all difficulties, can enable us to work out our "political salvation." Let us not deceive ourselves then, with the vain belief, that our progress in this work will be every where cheered by the approving smiles of our country, and the cordial support of our fellow-citizens. Conscious that we are actuated by the purest motives, and that "all the ends we aim at are our country's," we must nevertheless be prepared for all manner of opposition. The measures we propose come into conflict with too many deeply-rooted prejudices, and too many adverse interests, to enable us to hope, that even our motives shall escape detraction, and our purposes misrepresentation. We have those around us, whose prospects in life, in a great measure, depend upon the defeat of our plans.

A large portion of the Union,—which always has exerted, and still exerts, almost a controlling influence upon public opinion, at home and abroad, will be roused into action, to deprive us of public confidence, and to drive us from our course. We shall be ridiculed, as the supporters of wild and Utopian theories;—as visionary enthusiasts, wasting their strength in the pursuit of impracticable schemes. We shall be charged with ungenerous prejudices, and unkind feelings towards our northern brethren, (feelings which are strangers to our bosoms,) and the *stale*, though *potent slander*, will be revived, of HOSTILITY TO THE UNION. Now, if in the consciousness of rectitude, we are not fully prepared to encounter ALL THIS, and MORE,—if we are not unalterably determined to go on in our course, "through good report, and through evil report,"—if we are not firmly and unchangeably resolved to trample down all opposition—it would be better that we should stop here, and attempt to advance no farther. These difficulties are thus fairly stated, not for your discouragement, but that we may be fully prepared to meet them. If we are true to ourselves, we shall most assuredly triumph over all obstacles. The high character, intelligence, and influence, which compose this Convention, properly and zealously exerted, CAN NEVER BE PUT DOWN. It is as certain as the rising of the morrow's sun, that we shall achieve the emancipation of the south and south-west, if we are only prepared to make the efforts necessary to the accomplishment of the good work. We shall live down the slanders of our enemies, and in the rich fruits of a noble and peaceful victory, will find our best reward. The peculiar institutions of the south, will be fortified and strengthened,—the streams of a rich and varied commerce will fertilize our soil, while diversified pursuits will stimulate the industry, add to our wealth, enlarge the minds, and improve the character of our people. Civilization and refinement,—the handmaids of virtue,—will adorn our land; and the GREAT TRUTH will be seen, and felt, and acknowledged, that of all the social conditions of man, the most favorable to the development of the cardinal virtues of the heart and the noblest faculties of the soul—to the promotion of private happiness and public prosperity, is that of SLAVE-HOLDING COMMUNITIES UNDER FREE POLITICAL INSTITUTIONS—a truth hardly yet understood among ourselves, but which the future history of these states is, we trust, destined to illustrate. Animated by these sentiments, and influenced by these views—and with a firm reliance upon Divine Providence—let the members of this Convention now PLEDGE THEMSELVES to each other, and to their country, to GO FORWARD—firmly resolved to leave nothing undone that may advance our great and patriotic objects. Let us be prepared to make every personal sacrifice, and to use all just and honorable means for the accomplishment of our great work—unalterably determined to PERSEVERE UNTO THE END.

LEAD MINE IN NORTH CAROLINA.

It affords us much pleasure to state that a valuable lead mine has been recently discovered in the lower part of Davidson county.

The ore is the *carbonate of lead* which unites the advantages of great yield and very easy reduction, and the vein is said to be very extensive. The carbonate of lead has never been found in considerable quantities in Europe, but exists in abundance at the celebrated *Lamotte Mine* in Missouri, where, owing to the ignorance of the miners, it was until recently considered as worthless; but that mine having been taken up by a company who have brought the lights of science to their assistance, the carbonate of lead is now preserved with great care, and considered the most valuable ore.

The mine in Davidson has been purchased by Mr. Roswell A. King, whose skill and persevering industry are well known, and insure success.

LATE WORKS OF MASSACHUSETTS IN AID OF AGRICULTURAL IMPROVEMENT.

We have received several valuable publications, which exhibit evidences of the recent progress made in Massachusetts in promoting agricultural interests, both by the action of the government and the people. In addition to the other and greater merits of these several publications, one, far from unimportant, is, that they are published in the uniform and handsome form of large octavo, and the paper and typography are such as to be worthy of the subjects, and to facilitate the use, as well as to induce the binding and preservation of these and similar publications. In this minor respect, of form and appearance, these publications are very greatly superior to the documents published by the legislature of Virginia; though even that great inferiority is as nothing when compared to the immeasurable inferiority of the substance—the acts and works —of the commonwealth of Virginia in support of agriculture, compared to those of Massachusetts.

Among the most important, and the first in order of these publications, is the 'Agricultural Report of the County of Essex, Mass.' This is the first part of the labors of the Rev. Henry Colman, commissioner of the agricultural survey of Massachusetts, ordered by the legislature of that state; and though the subject is a county which is one of the least agricultural of a state which, if compared to Virginia, is generally but little fitted to reward cultivation, or improvement, still, the report is an earnest of the value of such surveys to agriculture, and of the ability of the surveyor and reporter selected for this noble work. In the foregoing pages of this number, we have copied parts of this report, which our intelligent readers will doubtless find interesting, if not instructive, notwithstanding the great difference of the circumstances of Essex in Massachusetts, and every part of Virginia. There is not a county in all the wide extent of Virginia, and no matter whether it be the best or the worst cultivated at present, of which a similar minute and careful report would not be highly interesting, and highly instructive, to a large portion of the farmers of our state; and if a general agricultural survey of Virginia were ordered, and properly executed, such as is now in progress in Massachusetts, it would do more good to agriculture, and to the general interests of this commonwealth, than the worst and most stupid course of any recent legislature has done harm; and that is a very strong assertion. But it is in vain to expect any such things here; and useless to refer to them, except to denounce, in deserved terms of reprobation and contempt, the legislation of a great state, much wanting and highly susceptible of profiting by agricultural improvement, which has continually refused the smallest aid to such improvement, and lends all its energy, and gives nearly all its labors, and all the spare revenue of the state, to endless and useless *talking* about federal relations, sustaining the bank-ocracy in its every iniquity, helping demagognes to the offices they seek, and giving fat jobs and profits to numerous individuals, under the false pretence of aiding public improvements.

The other publications referred to, which are strictly agricultural, are the 'Transactions of the Essex Agricultural Society, for 1837,' and separate memoirs of the commissioner of the agricultural survey, 'On the cultivation of Spring Wheat,' and 'On Bone Manure.' Another, which is principally and most usefully, though not entirely directed to benefit agricultural improvement, is the 'Re-examination of the Economical Geology of Massachusetts,' by Prof. Edward Hitchcock; which, in its general features, seems to compare with the geological reports of Virginia, pretty much in the same manner as the business-like and matter-of-fact doings of the legislature of Massachusetts, with the eloquent declamation and endless and fruitless speech-making in that of Virginia. Some extracts from this excellent and practical report, and also some animadversions on particular portions of it, may be given in this journal at a future time.

NATURAL COKE FOUND IN VIRGINIA.

"There seems to be no end to the mineral treasures of Virginia. Yesterday we heard of another discovery, which, according to present appearance, is destined to prove of incalculable service. The reader will recollect, that during the last autumn we spoke of a rich vein of iron ore, which was in a course of exploration, on the south side of the James River, near the coal pits, and from two to three miles of the river. The ore has been further opened; and we are happy to learn, promises to be of great value. It is under the auspices of John Heth, Esq., and is immediately on the new rail road, which will soon be opened, from the coal pits to the river.

But the discovery embraces a new object—a large and rich bed of natural coke, which is just below the iron ore—and is suspected of being in a large field—and of being near 17 feet thick. The coke was first discovered by those who are engaged in laying down the rail road. They thought of burning it as fuel, and the experiment has answered. It is said that Professor Rogers has pronounced it to be a natural coke—and we understand, that Mr. Deane is about to try its virtues in his iron rolling mill. Should it correspond with the indications which have so far transpired, it will prove a source of great wealth to its worthy, liberal, and enterprising proprietor—as well as of advantages to the rising manufacturers of Richmond.—*Enquirer.*

We have seen experiments made in the foundry of this city, upon specimens of the coke, found in Chesterfield county. In the course of an hour and 30 minutes, near 1200 lbs. of iron, brought from the mine near Fredericksburg, were fused; and the castings were uncommonly smooth.

There seems to be no doubt, that it will answer admirably the purpose of smelting the iron from the ore.

The fire, which is made of it, is intensely hot. It much resembles the anthracite; but it has a little more flame.

It is considered a very valuable discovery—and it is unique in this country. Analysis gives more than 70 per cent. of carbon—small portions of iron, earth and volatile matter.—*Ib.*

From the Quarterly Journal of Agriculture.

ON REARING DOMESTIC POULTRY.

It has frequently occurred to us, that the management of a poultry-yard is not so rationally conducted as it ought to be. When we consider the rapid advances that have been made of late years among the industrious classes of the community in intellectual acquirements, more especially in the southern parts of the kingdom—Scotland having been for a series of years an educated country, while the same classes in England were yet in ignorance—we feel warranted in our objections, because we have practically proved the fallacy of the "auld warld" methods of treating that portion of our live-stock, and have established our right to make those objections, by the success which has attended our own plan. The best test of our ability in the office which we can offer to our readers is, that we pay nature the compliment to suffer her to dictate to us, and that, as far as possible, we attend to her wise and simple laws. If this candid acknowledgment be in our favor, we fear not to gain proselytes from the old to the new method, and proceed to the detail.

In large farms, and among the very poor, it would not be desirable to have a poultry-yard portioned off; in the former case, because that part of the live-stock is subsidiary, in the latter, because the outlay, though trifling, would be too considerable. A very numerous class of persons, however, remain, to whom the rearing of poultry might be an object of emolument; and others again, who seek for no remuneration beyond the pleasure which arises from possessing the means of consuming those animals which are the produce of their own estates. In all cases it is gratifying to know and to follow a plan which leads to the most satisfactory results; and *that* is presumed to be the best, which is founded upon the experience of years. We will begin with

The poultry-yard.—This ought, when practicable, to be separated from the other portions of the premises devoted to live-stock, and even subdivided when various kinds of fowls are kept which are inimical to each other, as is the case with the guinea-fowls (or Pintadas, or Gallinæ, as they are indiscriminately called), and the more familiar tribe of cocks and hens. The yard should be dry, as nothing is so injurious as damp; in order to effect this, the surface should be gravel, on a foundation of chalk, for the benefit of quick drainage. This preliminary we consider all but indispensable; the difference that would be experienced in the well-doing of poultry that is reared on a gravel or chalk-paved yard from those that *draggle* through their existence on wet clayey ground or grass is astonishing. The yard should have a full exposure to the south, and contain an open shelter from either sun or rain. Within it should be placed dry sand, ashes, small gravel, and chalk, for the use of the birds: the two first named materials they require for the purpose of dusting themselves, a process in which they not only delight, but which is essential for their health; the fine gravel is constantly picked up by them, and without it, their food would not undergo a healthful state of digestion. Although the space allotted to them is to be separated from the general farm, it should be contiguous to a meadow or a common, for grass is absolutely necessary for them; a small opening should, therefore, be made in the fence, through which they may gain access to it. Instinct will teach the old birds to remain no longer than is needful; of chickens we shall speak hereafter. We have had opportunities of comparing the state of poultry which had been prevented from ranging among grass with our own that had never been debarred from it, and the results were so satisfactory to us that we cannot do otherwise than recommend the plan. No animal thrives well upon one only species of food; of man himself it is asked "can he live by bread alone?" The craving which poultry evince for a change of food is evident to all who will take the trouble to watch them; after having eaten well of variety, with a profusion of the grain yet lying before them, they will eagerly run to a common and finish their meal, upon the various aliments that are presented to their choice, grubs, worms, insects, and even of the grass itself they will eat very considerable quantities, when left to their own freedom, and this not now and then only, but daily, for they live very regularly. Their habits appear to be as fixed as those of mankind; they like to be abroad early in the morning, before the slugs, &c., which are most alert during the hours of darkness, have retired to the earth; they then return to their corn, which they rarely finish until they have been abroad. After having drunk water and dusted themselves, the hens proceed to the nests for the purpose of laying. They afterwards lie lazily about, take their *siesta* towards noon, then look for their mid-day meal; again sally forth to the grass, and rove about at their ease, until it is time for them to receive a third feed, when they retire to roost, in summer about six, in winter towards four o'clock.

The most approved species of poultry.—In a former number of this periodical, all the kinds are enumerated, and their different qualities specified, so that choice may thus be made. (See No. xxxi. December, 1835, pp. 372, 390.) We have but to observe that *white* fowls with short legs, are those to which we give preference. There exists a prejudice against them, that they are more tender than those with dark plumage; we have not found this to be the case, though we are decidedly of opinion that the flesh of the former is more delicate than that of dark fowls with black legs.

Poultry-houses.—If the number of fowls to be kept, be very considerable, it would, perhaps, be right to have two or three dormitories, in the event of infectious disorders appearing among the stock; but we do not offer this opinion as our own, having never experienced any illness of a contagious kind, nor having indeed lost any of our numerous stock, except from casualties and accidents. One roomy—nay, lofty fowl-house, will be sufficient where judicious attention is paid to the following particulars. Ventilation is highly requisite, for where numerous creatures congregate and remain shut up for many hours, an unhealthy heat will be generated, and a bad effluvia from the manure will stagnate and create disorders which would never exist if free ventilation and cleanliness were attended to. We have seen in those anomalous spots peculiar to England, yet christened by a French name, and styled "*Fermes Ornées*," where every item was pretty, and expensive, and ornamental, and artificial, and, consequently, liable to failure; we say, in such places, we have seen fowl-houses, barely seven feet in height, with plastered walls and *ceiled* ceiling, with close-shutting door, and a glazed casement, not made to open! The inevitable consequences were most offensive odors, and a sickly stock, which of course consisted of the most expensive, because rare species, and were continually obliged to be renewed.

Fowl-houses, we repeat, should be lofty, and securely closed in the lower part, to prevent the ingress of vermin, not only foxes, but stoats, weasels, rats, &c. The upper portion may be very open, as much so indeed as is consistent with due shelter from rain. As it is the nature of warm air to ascend, it is evident that the atmosphere which is heated with, and contaminated by, the creatures and their odor, will ascend and prevent the descent of cold air. The floor of the dormitory ought to be formed of any convenient material which will be found to be most dry, even, and commodious, in order to allow of its being frequently washed. In laying the floor, a gradual slope should be made towards the middle, or to one side, where a drain might carry off the moisture, after it had been scrubbed with a birch-broom. All good farmers and gardeners are aware of the value to their land of every kind of manure, and need not our recommendation to save every portion; hence, the drain from the hen-house will of course be made to communicate with the general reservoir of liquid sullage, which *every country homestead* ought to possess in the most convenient corner of the premises, where it could be covered in and kept from evaporation, by a rough building or shed erected over it. The boxes for nests should be constructed of unplaned boards, and fastened to the walls about three feet from the ground, and by no means should they be placed in the fowl-house; an out-building ought to be devoted to the purpose, where the birds may fulfil their duties either of laying or sitting quite undisturbed; a fowl-house appears to be sedulously avoided by poultry, excepting at the hours of rest. Clean straw, not very long, must be coiled round in the nests, but hay should never be made use of; the scent is said to be too powerful for the birds, and to harbor insects. We do not assert this of our own knowledge, but had we not heard any objections made to the use of the latter, we should give the preference to straw.

The fowl-house should be lime-whited every spring. The perches for roosting should be of different heights, but wider apart than the length of the larger sized birds, to prevent the fowls which may roost on the lower poles from being inconvenienced by those above them. A sloping board with slips of deal nailed on to it, at distances of three inches, should be fixed from the floor to the lower range of perches, to facilitate the ascent of chickens when they have left their coops, and begin to assume the dignity of roosting fowls. The door of the house should be set open every morning when the birds are let out, to preserve the place healthful by constant ventilation; and where no objection exists to its being kept open all day, there need be no other place of ingress and egress; where, however, such objection does exist, an opening must be made in the door itself at the bottom, large enough to admit the birds, which (the opening) should have a sliding board made to run in grooves, that must be closed in the evening when the fowls are locked in, and this is a precaution which no one will neglect who values his poultry. It will be seen that by closing the little door, we prevent all egress in a morning, until some one of the family may be stirring. Long experience has taught us the value of the regulation; for not only are the fowls thus preserved from the attacks of early marauders of every kind (and many persons would not hesitate to run down and appropriate a wandering pullet who would fear to rob a hen-roost!), but the young chickens are thus prevented from strolling into the grass while yet it remains saturated with rain or heavy dew; nor will the creatures be debarred from their favorite and natural morning meal by this arrangement, since, where animals are kept in an establishment, persons must be abroad sufficiently early to allow of their finding worms, &c., before the sun shall have exerted so much power upon them, as to drive them into their holes, and remove the dew from the grass.

Treatment of the Poultry.—Having cared for their accommodation, we will proceed to the birds themselves. The stock being chosen—in which we would recommend that some of the "everlasting layers" be introduced—the proprietor will commence his observations. A poultry-yard is replete with interest, but, as every one may not feel equally impressed with a sense of it, and, moreover, possess neither time nor inclination to give the subject personal attention, and thus gain experience for himself, we will do our best to impart our own. We are convinced, however, that if the "master's eye" be not upon the creatures of his farm, they will fare the worse. Servants, however faithful and trust-worthy, *cannot* accomplish all that is wished of their vigilance, nor can they feel that degree of interest which is necessary in the creatures committed to their charge. Their minds are not of the same calibre, their education has not fitted them to comprehend the philosophic motives which their employers might bring to bear upon the subject; hence, to have proper attention paid, it is absolutely requisite that a master should not only say to his servant—"Do!" but see that "he doeth."

A stock of fowls should consist of pullets and hens of from one to four years of age; they usually are supposed to decline after the third year; but when any good quality is evinced, such as being good layers, close sitters, or careful mothers, it is obvious that, to deprive ourselves of valuable dependents, only because "it is said" that they are on the wane at a certain age, is sufficiently absurd. It is a fallacy to deem those hens inferior which happen to possess large combs; it is equally a mistake to consider that those which crow like a cock are worthless; and to attempt to refute the popular superstition that it is "unlucky" to keep a crowing hen would be idle; it is too ridiculous to be further alluded to. The number of laying fowls, will, of course, depend on the wish of the individual, and his facilities for their accommodation. A large number is quite as easily attended to as a scanty stock. If only four, five, or six hens be kept, one cock will be sufficient, and it will be better to increase the stock by degrees, for a year or two, by allowing a young cock to grow, rather than to introduce another from a foreign collection. Battles and persecution would be, in the latter case, endless. A change of breed can always be accomplished, by procuring eggs from an approved stock. Eggs that are intended for sitting, "it is said," should not exceed a month old; and as, in a state of nature, a hen would occupy nearly that period in laying the usual complement of eggs, the rule is a good one; but a simple process, which we shall hereafter describe, whereby they may be preserved fresh, eatable, and *sittable*, for many months, will render all precaution as to the length of the time they may have been laid unnecessary. Fifteen eggs will be generally sufficient for hens of the usual size, though the very finest, healthiest, and most successful breed we ever had, was the produce of a white hen which had "stolen a nest," had laid sixteen eggs, and brought forth the whole number of chickens, every one of which she reared. We would not recommend that hens be allowed to sit until after the turn of days. Early in January, if the weather be mild, they will sometimes indicate a wish to incubate which need not be thwarted, if conveniences can be commanded for the accommodation of the mother and her brood. Constant attention, however, is requisite, and, from being reared totally under shelter, the chickens, like hothouse plants, will be so tender, that there is small chance of ultimate success. The same objection exists against attempting to rear a brood late in the autumn; the first week in September is the latest period at which it ought to be hazarded. There is yet another time, during which it is absolutely indispensable that hens be prevented from sitting, and that is the month of June. Close observation (after having suffered at that season numerous failures most unaccountably) enabled us to discover the cause, and thereby verify the truth of an old saying which we have since met with—

"Between the sickle and the scythe,
What you rear will seldom thrive."

We had noticed that chickens which were hatched during the month of July were almost all attacked about the time of their first moulting (a period always attended with much suffering to them) with a fatal disorder, the symptoms of which were unvarying. The chickens appeared to collapse, and moved about with difficulty, as if their joints were stiffened, or rather as if the skin had become tight and tender; their feathers became rough and stood out; their wings drooped and dragged on the ground; they refused sustenance; and becoming more and more weak and torpid, they, in a day or two, died off in great numbers. Every rational means was resorted to, in order to arrest, or even account for, the disorder; at length it was discovered, that they were in a high state of fever, and that the extreme redness of the skin was caused by the irritation of hundreds of that minute pest the harvest bug. Some—very few—were recovered by anointing them all over with oil and vinegar;* but the recipe is too rough for little delicate creatures, already enduring the pain attendant on the season of moulting. It became obvious, that the period during which harvest bugs are most numerous and tormenting, must be inimical to the rearing of chickens; and that, if the hens were not allowed to sit in June, or rather, if the chicks were either strong enough to cope with the evil, or were not hatched until the season for the pest had passed by, that the destruction might be prevented, and so it has proved.

We do not suppose that we are addressing readers who are entirely ignorant on the subject of poultry, and therefore omit the more obvious and simple directions and information: such as the indications by which it may be known when a hen is inclined to sit; how long a time elapses before her chickens will be hatched, &c.; yet we would not that one reader should be disappointed by the incompleteness of the subject on which we are writing. It may be as well therefore to state, that when hens shall have laid from ten to twenty eggs, they generally, but not always, show the first symptom of a desire to incubate, which is remaining a long time upon the nest; they then begin to cluck, and their combs lose that bright red color (the infallible sign of good health, and disposition to lay) which they had shown. Very young hens sometimes deceive by evincing all these symptoms, and will even take to an empty nest, and remain close for a day or two, yet directly after they are put in possession of all they appear to require, will capriciously leave the eggs and resume their usual habits. It is customary to place an odd number of eggs under a hen, not "for luck," as the auld wives suppose, but because they lie more round and compact. A large sized hen will cover fifteen well; but if she find the number too many, she will reject one. Should an egg be broken it must be removed, and her feathers washed from the clammy substance. For the first few days, some hens will sit so steadily, that they will not leave the nest for food. Fears have been expressed for the lives of hens under these circumstances, but we incline to think they might be left to nature; however, no harm can accrue from lifting them off the nests and placing food and water ready for them in the open air. They are refreshed by the change, and resume their solitary duty in comfort. Food and water should always be provided for sitting hens once a-day, and that at a time when they cannot be persecuted and driven away from it by their congeners, namely, either before the fowls are let out in a morning, or after they have retired to roost. The plan of feeding them on the nest is perfectly erroneous, and contrary to nature. It is requisite, for the sake of cleanliness and health, that hens should leave it once in twenty-four hours. As an attention to cleanliness is indispensable in every department of a homestead, we need scarcely mention that clean short straw should be provided for every sitting hen, and the nests be thoroughly cleaned out when the brood is hatched.

---

* It should be known, that this is the best, nay, the only remedy for the annoyance which human beings experience from the same cause.

It is much to be deplored that, in subjecting creatures to our use, we cannot make their comfort a greater object of attention. Granting that man has had control given him over the brute creation, it surely would prove his fitness for the gift that he should exercise his authority with kindness, and temper his power with mercy. If nature must be thwarted, it should be effected in the gentlest manner. It sometimes happens, for example, that it is desirable to prevent hens from sitting, when eggs are more in request than chickens: to obtain this end, we have known very cruel methods practised, such as plunging the poor birds into water, swinging them violently round. &c. The most effectual plan, and the one least objectionable, is to confine them under coops, in a dark place, with plenty of clean water, and a rather short allowance of food, for two or three days. If on restoring them their liberty they should return to the nests, a repetition of the discipline for another day or two will generally be found an effectual preventive. By watching the denizens of a poultry-yard, not only much amusement is afforded, but no little information of a practically useful nature may be obtained. It will be seen which of the hens evince a disposition to sit, which to lay eggs, &c., and we ourselves enjoy the comfort of gratifying rather than crossing their instincts, by attending to these indications. When a hen has sat three weeks (twenty-one days), arrangements should be made for the young brood, but no interference should be allowed. Man is so conceited, that *poor bungling nature* cannot be expected to proceed in any of her operations without his assistance! How could chickens break the shell if he were not kindly to aid them? When he or she has efficaciously taken this duty from nature, he carries the little fragile things in his rough awkward hands, pokes them into a basket with some hay, which he sets before the kitchen fire, having first pulled off the scale at the tip of their beaks, forced open their jaws and thrust a pepper-corn down their throats. Then enter "a whole tide of children" and maid-servants, all eager to look at and fondle the "pretty dears!" and, in the struggle for precedence, down goes the basket with its half-dead inmates, which is forthwith picked up, and the creatures thus stroked and pitied, and exposed to cold, and again attempts to feed and nurse them, survive their rough entrance into life by a miracle. We repeat—there is no occasion to intrude upon the hen while she is hatching her brood, nor ought we to do so. The chick that requires to be assisted from its shell will be too puny to be worth the rearing. The mother may be left with safety, nay with benefit, for even forty-eight hours from the time that the chickens begin to come forth. The fine instinct with which she is endued, will enable her to perfect the work of which she has been for three weeks the sole artificer. She will assist the little prisoners, and throw away the intruding shells; she will liberate their beaks from the scale, and "*cro-o-o*" to them, and dry their clammy down, and foster them in the genial warmth of her breast, and they will be strengthened and nourished by the yolk, which is said to form no part of the chickens, but to be retained in the intestines, for the purpose of affording their first aliment. However this may be, certain we are, that the brood thus left to the mother's care, will be stout and strong when (the whole being hatched except those eggs which may be addled) the two days are expired, and quite ready for the food which has been provided for them. A coop should be put in a sunny spot, but *not on grass*; under this the hen and her family must be placed, with groats, a little barley, and clean water, in a chicken pan or a garden-pot saucer. They should be fed little and often with groats, a few grains of barley being always thrown to the mother, which she will peck and split, and call her young ones to partake of. Every day the coop should be removed to a little distance, so that the creatures may be clean and dry; and each morning too, a fresh sod of grass turf ought to be placed inside the coop for them to scratch and demolish, to obtain any worms or insects that may be lurking among the roots of the grass. It is usual for hens to be detained in their coops for a month: we object to this decidedly. Indeed, where the range is small, and the situation inclosed, we prefer that nature should be seconded, and the maternal anxieties indulged, by setting them free after the first two or three days.

Food.—We have stated that groats are the best aliment for chickens, but they may be discontinued as soon as it is perceived that the young ones are able to eat whole barley. That food which is most nutritious is the most proper for every animal, and will be the cheapest in the end. While we were buying our experience, we made trial of all kinds that are usually given, tail-wheat, inferior barley, sunflower seeds (of which last we grew an immense quantity, on purpose to make a fair trial of the assertion, that this food would impart the color and flavor of game to the flesh of domestic fowls, and which we found to be a fallacy), maize or Indian corn, potatoes boiled, and barley of the best quality. It must be confessed, that Indian corn is the aliment they most preferred, but as it is now very little cultivated in this country, it is too expensive, unless within a short distance of London, Liverpool, &c., where it is imported from America. The best barley, therefore, and plenty of it, should be given with a few peas in the winter; occasionally some boiled potatoes, the latter merely to amuse them, with a few green leaves from the garden, such as cabbage, lettuce, &c., to supply the place of their favorite grass, when sultry weather may have deprived them of that daily treat. Clean fresh water, should be their only beverage.

We abjure the system of cooping previously to killing, on several accounts; it is not necessary, it is cruel, and it induces a state of disease, instead of health. That it is not necessary, is evident from this fact, that a "barn-door fowl" has always retained the supremacy over the more grossly fed poultry of the metropolis; that it is cruel, need scarcely be pointed out to the most unobservant; that it induces disease, is a fact which will not be doubted, when we consider that we alter the creatures' habits, debar them from exercise, and prevent them from having recourse to those instinctive enjoyments, which contribute to health. If poultry have been well fed always, they can require no fatting; if they are healthful, they are in the fittest state for the table. The longest period of confinement which we consider necessary, is three days; on the first two, we give them barley-meal instead of barley, because, being unable to procure small gravel to assist in digesting that hard food, it is better to substitute an aliment which is softer. On the third day, they should eat nothing, that is for twelve hours, before they are killed.

The horrid system of cramming, that disgrace to these enlightened times, we cannot too strongly reprobate! It is grievous to reflect upon the innate cruelty of nature which man possesses; we regret to think it innate, yet such it must be, for if it proceeded from ignorance, our educational systems ought to have instructed the community; if from the remnants of our barbaric origin, civilization and sociality should have shamed human beings into humanity! Cruelty and cowardice are inseparable; the more weak and unoffending the objects, the greater is his delight to torture them. How vitiated, too, must be the taste of those who can endeavor, and thereby encourage, this torture of creatures which are over fed, and consequently in a state of disease!

One of our best writers on domestic poultry, Bonnington Mowbray, Esq. (whose able work is nevertheless tinctured with irrationalities) thus speaks of this vile custom, in his "Practical Treatise on breeding, rearing, and fattening domestic poultry," page 69.

"The Workingham method of feeding, is to confine the fowls in a dark place, and cram them with a paste made of barley-meal, mutton-suet, treacle, or coarse brown sugar, and milk, and they are found completely ripe *(ripe!)* in a fortnight. If kept longer, the fever that is induced by this continued state of repletion, renders them red and unsaleable, and frequently kills them. I must presume to repeat, it appears to me utterly contrary to reason, that fowls fed upon such greasy and impure mixtures, can possibly produce flesh so fat, firm, so delicate, high flavored, or nourishing, as those fattened on more simple and substantial food, as for example, meal and milk; and I think lightly of either treacle or sugar. With respect to grease of any kind, its chief effect must be to render the flesh loose, and of indelicate flavor. * * * * * Real excellence cannot be obtained, but by waiting Nature's time, and using the best food. Besides all this, I have been very unsuccessful in any few attempts to fatten fowls by cramming, they seem to loathe the crams, to pine, and to lose the flesh they were put up with, instead of acquiring fat: and where crammed fowls do succeed, they must necessarily in the height of their fat be in a state of disease."

In and around London, the trade of fatting fowls is at once extensive and lucrative. The state of misery in which these poor victims to the cruelty and gluttony of the coarse-feeding citizens and their caterers, drag on their existence, is truly pitiable; shut in from pure air, and the enjoyments of liberty, cooped up and gorged against their will with food abhorrent to their taste; what well-regulated mind does not revolt from the contemplation, and who would not rather partake of even inferior flavored poultry, rather than encourage a trade so degrading to humanity!

But we maintain, that the rational plan which we have detailed, will ensure a supply of the finest poultry that can be reared; thus, in discountenancing the cramming system, "virtue would be its own reward."

Our remarks on this subject being the result of experience, and our plans therefore practical, we feel no hesitation in promising the same success to all who may adopt them, which has attended ourselves. We are fond of experimenting; and having tried every known method to preserve eggs, and found *all of them fallible:* we discovered a simple method, which we have proved to be unobjectionable. It is well known, that while the yolk of an egg remains surrounded by the white or albumen, the egg is good. Few of our readers can have been so fortunate as to have escaped that breakfast-table infliction—a stale egg; and they will not fail to have observed, that on one side of it there exists no white, but that the yolk is in close contact with the shell? This alteration in the position of the vitellus or yolk, is the cause of the annoyance; the shell is porous, and as soon as that portion of the egg, which is intended to constitute the food of the chicken, and is consequently liable to corrupt on being exposed to the influence of the atmosphere, sinks through the surrounding medium, which contains (and perhaps partakes of) the vital principle, and touches the shell, the process of decomposition commences.

To retain the yolk, then, in the middle of the white, is the desideratum, and this we have succeeded in achieving for many months. We had failed to preserve them in bran, sand, ashes, salt, lime-water, hanging them up in nets, and scalding them; the last-named plan, however, though objectionable, is the best, excepting our own, which consists merely in turning them every day, and is thus contrived: A frame of wood, two feet long by one wide, and two inches in height, has strong copper-wire strained across from end to end and side to side, to form squares large enough to allow eggs that are of a medium size being placed in every alternate space; the wire to be twisted at each corner of the reticulation or intersection. In private families, the number of eggs will rarely exceed those of the square receptacles contained in one square frame, and can therefore be with ease turned every day, (forty or fifty being reversed in one minute); but when eggs are kept for sale, or on a large scale, hundreds could be managed in the same short time, by having several of these frames made to fit on to one another with handles, so that the whole stock might be turned at once. The plan is excellent, yet susceptible of much improvement. In the event of packing eggs for sea voyages, it would be invaluable, if the slight attention they require could be commanded.

Diseases.—Of the disorders to which poultry are liable, we really are practically ignorant, having for many years been so fortunate as to experience few or no instances of disease among our stock; and we attribute the health of our various animals in the farm-yard, entirely to strict attention to cleanliness, diet, and rational treatment. Those who listen to the advice of the ignorant and prejudiced, nay, they who seek from books remedies for disorders which may appear among their live-stock, will have to contend with monstrous absurdities, excessive ignorance, and barbarous cruelty, in the quackeries recommended. Nature will generally effect a cure, if her efforts are seconded by simple means on our own part. Calomel, sulphur, rue, pepper, and gin, are all absurdities, though all recommended for the ailments of poultry.

Ducks.—Large-bodied and dark-feathered ducks, are generally finer flavored than those with white plumage. It is not usual for these birds to lay more eggs than they can hatch, though occasionally, a valuable individual may be found in a district, whose wonderful achievements in laying, as well as hatching, two and three broods in a year, are recorded.

Their indications of a wish to incubate, though not so obvious as those of hens, are nevertheless sufficiently marked; and no one who is not very unobservant, can be deceived. We are averse from the plan, of placing duck eggs under a hen to be hatched. It is not only cruel, to keep the poor bird a whole week longer in her office, (for they require that extra period), but nature is thwarted in those fine instincts of that proud and happy period of her life, by the untoward habits of her nurslings. A pond is not essential for the well-doing of these fowls. If a large shallow tub be sunk in a convenient spot of the premises, to which the old birds can have access, in order to dip and wash themselves daily, it is all that will be required; and indeed, young ducklings ought not to be permitted to go to any water for the first six weeks, excepting that contained in wide shallow pans, in which they will dabble occasionally without injuring themselves; whereas, if they were allowed to follow their mother to a pond, they would remain too long, and be liable to become cramped.

The same objection exists with respect to cooping ducks upon grass, which attends that locality for chickens, namely, danger from damp. We cannot too strenuously impress the necessity to guard poultry from exposure to moisture; dry cold, however severe, is seldom inimical to them. If the coops be placed on grass, even in hot and arid weather, there are heavy dews in the early morning, into which these little creatures will *wander*, *draggling* their downy covering, and ensuring an almost certain death from cramp, or, if ducks, from that complaint locally and vulgarly called "the sprawls." It is very desirable, however, that they should be admitted into a field for a few hours every day, when the weather is dry. Barley-meal is the best food for ducklings. It should be frequently renewed, as well as fresh water in their pans, as often as they shall be emptied by the splashings and dabblings of the little brood. Straw should be placed in a coop with a duck, but not with a hen, as the young ones of the former being constantly wet, require to be dried as well as warmed, when they retire to the shelter of their mother's breast for occasional repose. As the ducks approach to full growth, one of their three daily meals should consist of whole oats, which must be thrown into a pan of water, for this food they will seek with avidity and delight; their natural manner of feeding will be thus imitated, which is effected by *sifting*, as it is called. The fine network at the edges of their bills suffers the water to pass through, but retains whatever particles of sustenance may be floating in the fluid.

Ducks are more easily and pleasantly reared than chickens; for unless the fences round the gardens and pleasure-grounds are close and high, the latter will infallibly effect an entrance, and distort the gravel-walks by their vigorous scratchings, much to the discomfiture of a gardener's equanimity.

We repeat, that good, nay, *high feeding from the first*, is the best way to obtain fine, firm, full-flavored birds; to say nothing of the comfort that a proprietor must derive, from the certainty that those creatures over which he has control, are in the enjoyment of the few requisites which constitute their happiness.

Geese.—What is more delicate than a young well-fed goose, from September till January; what more rank and detestable than an old, tough bird, quickly fatted on the greasy abominations that constitute the food of those which are too frequently to be met with at a poulterer's. It is quite a mistake to suppose that a Christmas goose *must* be coarse and strong: those who depend upon a purveyor will rarely find it otherwise, we admit; but they who have reared these birds, and attended to their regular feeding, can refute the assertion. If it be desirable to fat two or three, with the intention of enjoying the treat at that festive season, without the trouble of hatching a brood, we would advise that the number be purchased from a flock half grown, at the beginning of autumn. It is not necessary for them to have access to a pond, a deep pan or trough, constantly, that is daily, supplied with fresh water, will be sufficient. Three feeds, one of barley-meal, one of dry barley, and the third of oats, every day, and water only to drink, should be their sole aliment for the last fortnight of their existence; before that time, they should have the run of a common or some waste piece of grass, for of this green food they eat largely; but they make a pasture unbearable to animals, therefore should never be admitted where cattle are grazing. During the last week or two, they may be confined during the day within four hurdles, (which ought, for the sake of cleanliness, to be removed every alternate day,) and driven under shelter at night. As they are social birds, they will not thrive alone, two or more must be fatted together, or they will pine and lose flesh rapidly. *A lag*, as it is locally termed, consists of a gander and five geese. If the spring be mild, the latter will evince indications of wishing to sit, in the open weather of February, when a bundle of clean straw should be placed in an open shed, of which they will proceed to construct their nests, side by side, without requiring any assistance or attendance. It is surprising that any mystery should be made, or difficulties thrown in the way, of so simple a matter as rearing poultry; nothing can be *more simple*, or certain to succeed, where a few rational rules are kept in view, and attended to. Cleanliness, dryness, kindness, and full feeding, are the secrets of success. Geese grow with great rapidity, and require a large quantity of food, and at frequent intervals; indeed, what young creature is an exception? Children ought to be allowed as much nutritious simple food as they desire; adults require less in quantity and at longer intervals. The treatment of a goose with her young brood ought to be the same as that which we have detailed, for the duck, substituting (for a coop) a crate, such as glass and china are packed in, with a sack or mat thrown over the top, to protect them from rain. Barley-meal to be the first food.

Plucking.—Suffering of all kinds, especially unmerited suffering, among those unoffending creatures, which we make subservient to our wants, is always distressing to an unvitiated nature; it behoves every one, therefore, to discountenance the tendency to inflict pain, in which hard natures and mercenary beings are apt to indulge.

We cannot place the cause of the unfortunate geese in better hands than those of the humane writer whom we have before quoted; he thus speaks of the wicked practice of plucking them:—"The goose is a considerable object of rural economy, and kept in large flocks, in the eastern and fen counties of England. In some of those parts, their geese are exposed to the cruel operation of being annually stript of their feathers; and it has been said, that fowls plucked alive have been sold in the markets at Edinburgh. Indeed, the interested feelings of man know no scruple, and the cruelties practised upon the poor sea-fowl, which have their down and feathers torn from them, and are then cast into the sea to perish, are enormous, and yet it would seem irremediable. Not so the disgusting barbarity, under the insane idea of sport, formerly, perhaps even now, practised in Scotland. These harmless fowls are hung up alive by the legs, and savages, men and boys, ride at them full speed, catching them as they can by the neck; and there can be no doubt that the horribly pleasing process of roasting a goose alive, as detailed by Dr. Kitchener in his "Cook's Oracle," a book invaluable equally to the gourmand and the economist, was actually practised in former days; indeed, we have proofs innumerable, and utterly disgraceful to this enlightened nation, of the absolute necessity of amending the enthusiastic and indefatigable Martin's bill, and rendering it completely comprehensive. It would have the effect of teaching men to think and feel, and to be convinced of the horrible and unnatural error of deriving pleasure from the racked and tortured feelings of other animals endowed with feelings similar to their own. A writer in the Monthly Magazine, December 1823, remarks humanely on the cruelty of plucking living geese, proposing a remedy which I should rejoice exceedingly to find practicable and effective. He remarks on the the additional torture experienced by the poor fowls, from the too frequent unskillfulness and want of dexterity of the operator—generally a woman. The skin and flesh are sometimes so torn as to occasion the death of the victim; and even when the fowls are plucked in the most careful manner, they lose their flesh and appetite, their eyes become dull, and they languish in a most pitiable state, during a longer or a shorter period. Mortality also has been periodically very extensive in the flocks of geese, from sudden and imprudent exposure of them to cold after being stripped, and more especially during severe seasons and sudden atmospheric vicissitudes. The remedy proposed on the above authority, is as follows:—feathers are best of a year's growth, and in the moulting season they spontaneously fall off, and are supplied by a fresh plumage. When, therefore, the geese are in full feather, let the plumage be removed close to the skin by sharp scissors, the produce would not be much reduced in quantity, while the quality would be greatly improved, and an indemnification be experienced in the uninjured health of the fowls, and the benefit obtained to the succeeding crop; labor also would be saved in dressing, since the quilly portion of the feathers, when forcibly detached from the skin, is generally in such a state as, after all, to require the employment of scissors."

The Pintada, or Guinea-fowl.—This bird is much esteemed for the fine flavor of its flesh, which more nearly resembles that of the pheasant than any other, and is in season when the latter is out of request. *It is said* to be reared and domesticated with greater difficulty than the usual inmates of the poultry-yard. This is not the case; nor is it "delicate when first hatched," as writers assert. It, however, is more wild in its nature than other fowls, straying to a distance, and depositing its eggs under hedges, among furze, or even in the most exposed spots, where every chance passenger may more readily obtain possession of them than can their owner.

We prefer to intrust a brood of pintadas to the care of a common hen, rather than to that of its own species. Their habits are not dissimilar,—as is the case with the duck,—and her nature will not be outraged in bringing them up. A hen will, with ease, cover seventeen or eighteen pintada eggs, as they are smaller than those of the common fowl.

We repeat, they are not difficult to rear; we have never lost a chick, except by accident. In consequence of their small size and minute beaks, it is requisite that their first food (groats) should be broken for them. They are exceedingly fond of, and thrive rapidly on ants' eggs,—whole nests of which should be sought for, and brought to them with a shovelful of the mould in which they are found. This, if thrown partly within the coop, the mother will amuse herself with scratching, while she at the same time instructs her chicks to seek for their own sustenance.

We have been surprised to find, that in books professing to give the natural history of this bird, its disposition should be courageous: it is the most remote from courageous; it is cowardly, fierce, and tyrannical in the extreme. These birds persecute all other inmates of the poultry-yard, with relentless perseverance, *but always in a body*. We were, on one occasion, witness to an assault upon a solitary pullet, by eleven pintadas. They surrounded their victim, pecking it with violence, and whenever one of the inner range of assailants received a blow from the poor bird, it retired to the outer circle. A very few minutes would have sufficed to destroy the pullet, but fortunately, the dastardly creatures were driven away. Their beaks are remarkably strong and sharp when they are full grown.

Their cruelty to all other poultry passes imagination. While among themselves, they are placid and affectionate; hence they ought either to be kept in a separate yard, or, if that arrangement be inconvenient, the stock of poultry ought to be confined to these birds, or they should be rejected.

The treatment of pintadas differs so little from that of other fowls, that, with the foregoing remarks, we close the subject.

Turkeys.—The following observations and method of rearing turkeys are not the results of our own experience; but are from the pen of the gentleman above quoted. We have refrained from keeping them, being deterred by fear of the trouble and difficulty which writers have thrown in the way; though, in consequence of the gratifying success which has attended us in our other feathered stock, we have no doubt our attempts would have been equally satisfactory, as we have always *of late years* taken nature for our guide, and endeavored to treat them rationally. For example, although we have Mowbray's authority for the practice, we would not "withdraw the chicks from the nest, and keep them very warm." Turkeys are amenable to the same wise laws, that the common hen obeys; hence we should leave them to the more congenial warmth of the mother's breast. Indeed, we are no sooner instructed by this author to remove the chicks, than he renders the advice nugatory by saying, "The turkey, from sitting so close and steadily, hatches more regularly and quickly than the common hen." (!)

Who removes the chicks to a warm situation when the mother steals a nest, or is in a state of nature?

In the article of food, we have equal contradiction, as well as absurd directions; the chicks are to have curd, eggs boiled hard and chopped fine, oat or barley meal kneaded with *milk;* yet immediately afterwards adds—"milk is apt to scour them;" then why give it? Water is their natural beverage, and will *not scour them.* Then, in case of cold weather ruffling their feathers, they are to have half-ground malt with their meal, "and, by way of medicine, caraway, or coriander seeds." (!) Nor must we omit "artificial worms, or boiled meat, pulled into strings, in running after which, the chicks have a salutary exercise." (!!) He justly observes afterwards, that "superfluous moisture, whether external or internal, is death to the chickens, therefore all slop victuals should be rigorously avoided;" and in this remark we cordially agree.

Pea-fowls, tame pheasants, partridges, &c. we candidly own, we know nothing of practically, and, as they are only kept for amusement, abstain from introducing any observations on their treatment from the same work.

EXTRACTS OF PRIVATE CORRESPONDENCE, AND EDITORIAL COMMENTS.

The new French discovery in making manure. Le Couteur on the varieties of wheat.

Philadelphia, 22d *March*, 1838.

Dear Sir—I have directed a copy of the National Gazette of the 20th inst. to you, so that you may see in it a notice of the process of obtaining manure without the aid of cattle, invented by a Mon. Jauffret, of Aix, in France. What think you of it?

As usual, in communications on agricultural subjects, the notice is not satisfactory in its details. I am under the impression that it has reference to some nostrum such as the world has often been beguiled with, before now, for the cure of other evils besides poverty of soil, and that its value will prove as great as many of the infallibles which have had their day of popularity, and have passed away. I am strengthened in this impression, because of the difficulty of reconciling the facts stated with the law of subsistence being in accordance with the laws of the production of food, as is urged by my friend G. H. Walker.

There is a late production of a very different character, to which I beg to urge your attention: I mean Col. Le Couteur's work on the varieties, classification, &c. of wheat. It is a work of great merit, and I think its publication in this country would be a means of doing much good. The exposition which he makes of the relative value of different varieties of wheat, is very instructive, and enforces the necessity of attention to a choice of seed and purity of stock in a manner that ought to carry conviction to the mind of every thinking farmer.

The means of keeping a stock of wheat pure, by attention to the time of flowering of the different varieties, is also worthy of notice in this country, where the well-meant efforts of those who have been at much pains and expense to procure select and valuable varieties, are often rendered of little avail, for want of attention to this amongst other points of great importance.

The influence of different manures, as stated, ought to have a tendency to correct a bad practice which is almost universal in this country. I allude to that of applying stable and yard manures to the wheat crop. This error has often been remarked upon by the most intelligent of our writers on agriculture; but very little impression has as yet been made on the public mind. The statements of an author of the character and experience of Col. Le Couteur may perhaps do more to correct this evil practice than all the arguments that have been urged heretofore.

Without further comment on the work, I will state that Mr. Walker has a copy of it, which is now in my hands, and that he has kindly consented that I should offer it to you if you desire to republish it. I am aware that it has been noticed in the Farmers' Register; but supposing it possible you may not have seen more than the extracts republished, I desire to know if it would be useful to you.

* * * * * *

[The account of the French discovery in manure-making, which was sent with this letter, had before been selected for publication. It stands at the beginning of this number. We think, with our correspondent, that the plan is likely, in performance, to fall far short of its promise; and to form a new item in the long list of agricultural humbugs. Nevertheless, whether merely as agricultural news, or as information of higher order, it deserves notice and attention; and also fair trial from those who are able to make a trial. What we doubt, is the economy, or small cost of such speedy conversion of insoluble and inert matters, to soluble and active manure; for there is no doubt but that, by some means, every vegetable substance is thus convertible, and that, with the aid of time, natural causes are continually, and generally with effect, operating to produce such a conversion. The hardest wood—the driest broom-sedge, reeds, or pine leaves—in short, vegetable substances considered the most useless, or perhaps injurious to soil and growing plants, on account of their insolubility, are entirely composed of, and convertible to, the same chemical ingredients (hydrogen, oxygen and carbon,) as the richest and most succulent, and putrescent vegetable manures; and they vary but slightly in ingredients even from dung; the latter only having something, and that a very little, in addition to the three principal elements just named. Therefore, there is nothing incredible in the supposition that art may produce a chemical change, in a short time, which nature alone produces by slower action. The great objection to the usual and long continued processes of this natural conversion, is, that the larger part of the soluble products (especially on bad soils) are wasted, as produced; and this loss is still greater, usually, when man's ignorant labors, or practices of cultivation, are mingled with, and serve to impede the improving processes of nature. Even if this new French process of rapid fermentation is effectual, it will require to be seen whether it wastes more of the products than would natural causes and time, if permitted judiciously to operate, before the discovery can be deemed as adding to the farmer's means of obtaining and furnishing manure to his lands.

We have already given some account (from European journals) of Le Couteur's opinions; but would be still pleased to see his entire work, and to publish further extracts, or even the whole, if its length does not forbid. It is a curious and interesting subject, and one on which every farmer has much to learn.]

The law of primogeniture and English agriculture. Turnips and manure.

Holmesburg, Pa., March 22, 1838.

* * * * * * *

I saw little change in the agricultural districts, after an absence of seventeen years. How should there be? How can there be? Whilst that most iniquitous and most pernicious of all systems—the law of primogeniture exists? In the manufacturing districts, (the source of all the agriculture such as it is,) the change and improvement are wonderful. I *will* give you some account of both. I shall now have more leisure than I have had.

* * * * *

I have kept 9 cows and fattened 47 sheep *upon turnips* this winter; the latter with part grain. This is the true system—variety of food is every thing—because so obviously the law of nature; it is by far the best mutton I have eaten in the United States; and if you were to see the quantity of manure I have, you would be astonished. My farm is barely 100 acres. I manure from 35 to 40 odd acres annually, and sell all my hay and straw!!! It is a fact; I *eat* no straw, cornstalks, chaff, &c.; these things are not natural food—they are for litter, to keep the stock dry, clean, and warm, as blankets are for our use, and to keep, preserve, and increase the manure. When will farmers and planters learn and understand all this? To eat *straw* I hold to be the very worst and most costly and destructive of all agricultural improvement and economy.

* * * * * *

Draining in Scotland. Law of primogeniture as affecting agricultural improvements.

[The following extract is from the letter of a subscriber, who, as his words convey, was engaged, not very long since, in agricultural labors and improvements in Scotland.]

April 17th, 1838.

I have read with much interest and pleasure, the reprint of Johnstone's 'Treatise on Draining, &c.' The importance of this valuable addition to the pages of the Register, cannot fail to be appreciated by many of your readers. From having seen many of the improvements described in the treatise, I can fully attest to the practical value of the directions therein given, for the performance of such improvements; particularly those relating to embankments. Most of the extensive improvements of this nature, which the author has described, I have had an opportunity of seeing; and in one instance to which he refers, I believe, from his not very distinct reference, the embankments were constructed under my own immediate direction, from plans furnished by Mr. Stevens, of Edinburgh. These were on the banks of the Isla and Tay, (in Scotland,) extending to upwards of five miles in length, and of a height of from three to nine feet, on one of the estates of Countess Flahault. The modes of embankment, which Mr. Johnstone has so well described, I should suppose would be as available in many sections of this country, as in Scotland. I suspect, however, that the reclaiming of the tide-marshes in this latitude would be a much more difficult operation than in that of Scotland. Tides there rise to a great height; but at low water there is generally a sufficient fall to admit of the enclosed lands being completely drained of surface-water. The high lands being also immediately on the sea-board, admit of the alluvion brought from them being lodged or deposited at the confluence of the rivers to the sea, forming a soil of a fine permanent nature, and not liable, on being dried and cultivated, to sink or become lower, as your experience has proved to be the case in at least some instances here. The lands enclosed by some of these sea embankments are, for miles, many feet lower than high-water mark; and a breach would be attended with disastrous results. This, however, rarely occurs. The conflicting interests of proprietors of land have much retarded these and other improvements; such as straightening and embanking river-courses, &c. in Scotland; and I suspect the same obstacle would be met with in this country, in an increased degree. Landed estates here are smaller, consequently more numerous, and more frequently change owners; and the constantly increasing division of lands must increase and perpetuate the evil. This constant division of property in this country is, in my humble opinion, not the least obstacle in the way of real and extensive agricultural improvement; and nothwithstanding Mr. Walker's remarks on the laws of primogeniture and entail, (in your last No.) and whatever evils may attend the existence of these laws, that of being inimical to agricultural improvement, I think cannot practically be laid to their charge. I believe that eight-tenths of the lands in Scotland are under entail; and I presume that no country can present more spirited, extensive, and rapidly increasing agricultural improvements, in the same space of time, than have taken place in Scotland in the last half century. The proprietor there has the strongest inducements to improve his property, under these very laws, though he may also abuse them. Some may be "compelled to be lords, who ought to be draymen," or "clergymen, who ought to be butchers;" but it is now, happily for Scotland, at least becoming fashionable in high life to be acquainted with rural affairs; and many of the Scotch nobles would put many of the Virginia farming fox-hunters to the blush, were they to compare their agricultural knowledge. Every person of experience must know how much more profitably improvements can be carried on, on a large scale, than on a small one.

MONTHLY COMMERCIAL REPORT.

While great inertness in the spring trade has prevailed in New York, a fair portion has been transacted in the smaller marts south of it. Purchasers of dry goods and groceries, who usually resorted to New York, have been induced by the great difficulties attendant on inland exchanges, to obtain their supplies in Philadelphia, Baltimore, Richmond and Petersburg. Importations from Europe have been on a very small scale, and the demand for our products there will be reduced, as a natural consequence. The increased consumption of other countries, and the new markets for cotton goods which commercial enterprise, stimulated by the low price of such fabrics, is constantly developing, compensates in part for the deficiency of export to the United States; but the rapidly increasing product of cotton, renders a corresponding increase of consumption necessary; otherwise, the price of the raw material must decline so low as to check the cultivation.

The quantity already brought to market this year reaches about 1,450,000 bales, being 300,000 more than was received at the same period of 1837, and exceeding the total receipts of that year. Prices have consequently declined in European markets, and in all others where the currency is sound. In the south-western states, the currency and not the commodity depreciates. Prices are therefore higher in Alabama and Mississippi, where bank notes are at 20 to 30 per cent. discount, than in New York or Liverpool, where they are at par with specie.

The "experiment" which, contrary to the expectations of its projectors, drove specie from the country and from circulation, having almost ceased to operate, a reflux has taken place; and importations of the precious metals to an immense amount have recently been made, by the very parties who were accused by the 'experimenters' of creating the dearth.

The New York banks have already resumed specie payments; those of Boston partially, and the decision of the convention recently held on the subject is, that in all the Atlantic states, and some of the western, a general resumption shall take place in January, 1839. It is to be hoped that trade will then resume its regular channels; that banks will cease to be dealers in produce; and that something approaching to equality will exist betwixt the currencies of different states.

The demand for tobacco continues animated here, though not so in the English markets, where prices are supposed to have reached their extreme point. What course they will take, must depend mainly on the extent of the crop in the United States, the estimates of which differ very widely, especially as regards that of the western states.

The growing crop of wheat is very promising, and as the import has been much smaller than was expected, and the stock of flour in July will be moderate, there is a prospect that the farmers will be well remunerated. The quotations of last month may be repeated for all articles of produce in Virginia. Tobacco, $3,50 to $12. Cotton, 8 to 9½ cents. Flour, $7,25. Corn, 70 cents. Wheat, none.

There continues to be considerable pressure for money, and stocks of most descriptions are depressed. New manufacturing establishments are going into operation at Petersburg and elsewhere; and our neighbors in North Carolina are following the example. Several cotton mills, some of them extensive, are about to be added to those previously established.*

The opening of a regular communication betwixt this country and Europe by steam vessels, may probably be dated from this time. New York was enlivened last week by two such arrivals; one of them, in fifteen days from Bristol. Thus we have intelligence from Europe almost as speedily as from New Orleans by the regular mail. X.

USES OF SOAP-SUDS.

Let all your soap-suds be taken care of; it is good, or said to be good, by those who have tried it, who are older and more experienced than myself, to wash down young apple trees with. It is done by taking of a shuck and dipping in the suds, then rub the tree up and down pretty hard, and it will cause the trees to have a fine sleek appearance, and be clear of the old scaly-looking bark that we too frequently behold when we view an orchard. The oftener they are rubbed down the better. It requires but a small portion of one's time, and causes the trees both to thrive and look well. It is manure for the roots, &c. Soap-suds are very good for hogs which have been put up for fattening, and of course for those that run at large. It is said that it will clean them of worms, and make them hearty, and cause them to thrive faster. Soap-suds is also good to put on cabbages that are set out in our gardens. Pour it on them plentifully and frequently, and there will not be half so many lice, and it will cause them to grow very luxuriantly. I have an old neighbor, who has been the most successful man in raising and killing fine hogs, raising fine cabbage and fine fruit trees, that I have been acquainted with. He tells me that he is very particular in having all his suds taken care of; and by-the-by, he is famous for having good and choice fruit, as well as other things, at almost every season of the year.

GRANVILLE.

SUSPENSION OF COLLECTING AGENCIES IN VIRGINIA.

After April 1st, 1838, there will be a cessation of all collecting agencies for the Farmers' Register, within the limits of Virginia. Lest the motives of this measure should be misconstrued, we will say that we have every reason to be satisfied with our late general

* We would be obliged, by a correct statement on this subject from one of our Carolina friends, detailing the several establishments, number of spindles, looms, and annual consumption of cotton.

agents, and their deputies, in all their transactions of receiving and paying over subscription money. Nevertheless, the system works injuriously, to this journal at least; and we shall rely on the subscribers to the Farmers' Register to attend to the remission of their dues, by mail at our risk of loss; or by any other and cheaper or safer means of conveyance, which they may choose in preference.

The effect of employing collectors regularly, is to induce the greater number of subscribers to wait for their application. This can rarely be made to nine-tenths of our widely dispersed subscribers oftener than once a year, if so often; and even when the tardy application is made, those debtors only pay who would have paid earlier, through some other channel, if no collector's visit had been expected by them. In this way, the general effect is this; that we pay 12 per cent. for collecting a large proportion of the dues from the most responsible and punctual subscribers—and lose (whether aided by collectors or not) nearly all the debts of subscribers of character entirely different.

The suspension of collecting agencies is limited to Virginia, because, even without using the mail, every subscriber in Virginia, can send his dues to Richmond, if not to Petersburg, once a year. The agencies heretofore existing for other states, will continue, as republished on the cover of this number.

ERASURES OF SUBSCRIPTIONS.

Just before sending out No. 1 of this volume, the names of 128 subscribers to the Farmer's Register were erased, (in obedience to the rule of the Editorial Convention,) as indebted for two years and upwards, and whose arrears due for subscription amount to $1845. These are in addition to all the many previous erasures for the like cause. After the lapse of time enough for all such stoppages of the delivery to be observed by the least observant—and for payment to be made by all who have permitted themselves to fall so much in arrear merely through inattention and negligence—we shall send out notices to the remaining debtors in a different form, and more likely to have effect, than these sent heretofore. So far as we can know the facts, we shall never annoy, even by sending a bill, any subscriber whose recent losses or misfortune have rendered him *unable* to comply with obligations previously incurred. In any such known case, the charge of the *debt* itself is erased forthwith from our accounts. But a very different course is called for in numerous other cases, of persons who are not only able to pay, but who claim and hold respectable positions in society—and for some who are very wealthy, or stand exalted in office, or in public character, and who have received the fruits of our labor for 3, 4, and even 5 years, without paying any thing, and who may permit their names to remain, as now, erased, and the arrears unpaid. We have no legal remedy against remote delinquent debtors; their debts are *debts of honor*—or, if they will so have it, of *dishonor*, if they continue to disregard every notification of them, and will *compel* the public exposure of such long continued delinquencies.

THE FARMERS' REGISTER.

VOL. VI. JUNE 1, 1838. No. 3.

EDMUND RUFFIN, EDITOR AND PROPRIETOR.

THE ADVANTAGE OF OBTAINING SEED WHEAT FROM COLDER REGIONS. BENEFIT OF MARL AND GYPSUM ON SWEET POTATOES.

To the Editor of the Farmers' Register.

Berkeley, Charles City, April 5th, 1838.

I have thought some facts, resulting from my experience as a cultivator of the earth, might be acceptable to you, and therefore take the liberty of communicating them. The first in importance, is the success which I have uniformly met with in the culture of wheat, when good seed was procured from the north, or the mountains of this state. When the Lawler wheat was much approved in the county of Frederick, although never *very* productive, I procured two bushels, which were sown late in the season, and on a very poor piece of ground--all of my good land having been previously sown. The produce of the Lawler, however, was 43 bushels of as beautiful wheat as I ever saw. This was used as seed, and produced a crop of about 800 bushels, weighing 61 lbs. 12 oz. per bushel, as reported by my friend Mr. Nat. Nelson, who kindly delivered it for me during my absence from home. The 3d crop from the same seed was an indifferent one; and the 4th utterly worthless--having been destroyed by rust. A year or two afterwards, I obtained from the same county of Frederick, a white plump wheat, known there as the "skip-back;" 5 bushels of this were sown on as many acres of good land, being the lot below my garden. Its yield was 35 bushels per acre. The subsequent crop, from this as seed, was an immense one. I cannot determine exactly its amount, but it was nearly all of a crop of 3600 bushels. The third crop from the same wheat was an average one, but the 4th disappointed my expectations. I have obtained other seed since, and the results correspond with this statement, that northern or western seed, when good, was to be relied on with confidence for two seasons; afterwards, I think it rapidly deteriorates.

The first Baltimore or golden-chaff wheat I ever saw, brought into this neighborhood by Williams Carter, Esq., consisted of one quart obtained in Pennsylvania; the produce of which was, according to my recollection, not less than three bushels. This, for several years, was preferred to all other wheats, as decidedly the most productive. The same gentleman was the first in this county to cultivate the purple straw; and for two or three years with great success. I am satisfied, from these facts, and others within my knowledge, that our crops of wheat would be much more certain if we were to rely on the north or west for as much seed wheat of which the second year's produce would furnish a sufficiency of seed for a full crop. For instance, I have never made less than 20 bushels per acre from such seed the first year, and generally quite as much the second. Every farmer may determine for himself what quantity is therefore necessary to obtain in the first instance, to furnish himself with a sufficiency of seed for a crop.

Another fact which I deem worthy of record is, my success last year in the sweet potato crop. I have for many years attempted sweet potatoes, to oblige my little ones, but there was really no crop, a few scurvy roots were all we could boast; and having no idea of the product, I directed, in the absence of my family, 20 hills to be dug in October for my own use. I chanced to be present when the digging commenced, and really was astonished at the yield; the first hill producing one peck, the largest of which weighed 5 pounds; and I have no doubt the product, although not measured, was not less than 200 or 300 bushels per acre. This excellent crop was owing entirely to an abundant use of marl and plaster of Paris, and certainly yielded the best and largest potatoes I ever saw; many, very many of them, weighing from 5 to 7 lbs. each. The soil in which they grew was quite light, and inclining to sandy. The seed was procured from Mr. Isaac White of Richmond. Very respectfully, &c.

BENJ. HARRISON.

[The opinions expressed in the foregoing communication, are altogether in opposition to the theory of Dr. Bronn, which we published in the first volume of this work, and to which we have several times referred with approbation. The rules deducible from that theory would require, that crops cultivated and mostly valued for their seeds, (as all grain crops,) are improved, or preserved in greatest perfection, by being raised from seeds grown in warmer climates, or on warmer and drier soils; while crops valued not for the quantity of seed, but for the whole bulk of the plants, in stalk and leaf, (as grass crops) are improved in bulk, though at the expense of the quantity or perfect formation of the seed, by being raised from seeds brought from colder and moister climates, or soils. From the confidence we had placed in these views, we should have considered Mr. Harrison as mistaken, if he had merely judged the product of the new wheats to be the greatest by the visible superior growth of the stalks, or greater bulk of straw; which might well be the case (according to Dr. Bronn's theory,) though accompanied by a reduction in the quantity of grain. But the products were ascertained, in these cases, by actual measurement; and there can be no higher authority for facts, or correct deductions from known facts, than our correspondent; and theoretical reasoning, however plausible, must yield to facts, correctly understood. At any rate, the information is interesting, and the results well worthy of being tested by the equally careful experiments of other farmers.]

PHOSPHORESCENT PLANTS.

M. De St. Hilaire says that the *agaricus (Olivier)* gives out a yellowish phosphorescent light in the dark; and it is supposed by M. Vallot that the notices of phosphorescent plants in ancient writers refer to that of the agaricus. There are, however, flowering plants which also emit phosphorescent light; such as the *Euphorbia phosphorea L.*, the milky juice of which possesses this quality. *(L'Echo du Monde Savant.)*

For the Farmers' Register.

PERPETUAL FERTILITY OF CERTAIN SOILS.

The following extract is taken from an interesting and scientific work, entitled "Travels through the Western Country, in the summer of 1816, by David Thomas."

"The fertility of the sandy prairies near the [Wabash] river is very remarkable. If lime is a constituent of this soil, the portion must be inconsiderable, as acids produce no effervescence. Neither is the vegetable matter in much quantity. The finer parts diminish but little in the fire, and are changed from a black to a reddish-brown. Hence the fertilizing principle is a mineral earth.

"The idea of soils *perpetually fertile* was not original with H. Davy, though to him we owe the first scientific view of the subject. Vegetable matter soon dissipates; but the primitive earths are imperishable; and if my conjecture is correct, these prairies will be sources of abundance through distant ages. A field was pointed out to me, which had recently been enclosed from the commons of Vincennes, and which produced corn of extraordinary luxuriance. From the nakedness of this ground it is evident, that a vegetable soil would soon become steril.

"One of my correspondents remarks, 'we have a prairie below this place, which has been in cultivation for seventy or eighty years, and now produces well.'

"Lord Kaims mentions a field near the Clyde, in Scotland, which had annually produced a crop for 101 years, and still retained its fertility. The subjoined extract is from the 'Edinburgh Encyclopædia.' 'The lands of St. Iago, (Chili) though constantly cultivated for two centuries and a half, without receiving any artificial manure, have suffered no diminution in their amazing produce.'

"Some of the great bottom of the Mississippi, between Kaskaskia and Illinois 'has been in cultivation 120 years, and still no deterioration has yet manifested itself.'"

I have made the above quotation for the purpose of adducing a few instances of almost equal fertility, presented by some of the soils of Eastern Virginia, apparently of very diverse constitutions. In none of them, as far as I am aware, has any portion of lime been detected. That the presence of lime gives fertility and durability to soils is fully demonstrated by all practical and scientific writers on agriculture; but that equal durability should characterize other soils, of which lime [in its usual state of *carbonate*] forms no constituent portion, can only be accounted for on the supposition of the existence of neutral soils, as promulgated by the author of the "Essay on Calcareous Manures."

There is probably no soil in Eastern Virginia, nor indeed in any part of the state, which is superior to the best of the ferruginous lands in the vicinity of Beaverdam, Goochland. It is an aluminous mould, in which the clay forms so great a proportion, that in times of rain it is as adhesive as mortar; though in a dry state, the surface is light and puffy. It is so red, that the line between the soil and subsoil is not always obvious. The neighborhood was settled about the year 1712; consequently much of the land has been in cultivation upwards of a century. When it is considered that the system of agriculture, which has prevailed, has been one of continual cropping—that heavy drafts have been yearly made upon the soil without its having received any aid from ameliorating crops, or artificial manures—and when it is moreover known that these lands remain to this day highly productive, it must be admitted that they merit the title of being almost "perpetually fertile." The farm of the late Geo. Pleasants may be cited to illustrate the truth of what I have stated. In the worst seasons, it never fails to produce a fair crop; and in years of plenty, it is now capable of yielding twenty bushels of wheat to the acre. Under an improved system, and possessing, as has been evidenced by the effects of one or two partial crops of clover, the greatest recuperative powers, it is expected that the present proprietor, who has inherited this valuable patrimony, will soon advance its condition to that state of productiveness of which it is so susceptible.

There are some portions, however, of the Beaverdam lands, that are rendered almost steril by a superabundance of isinglass or micaceous earth. This ingredient not only destroys their adhesion, but prevents any permanent improvement from being effected, even by the most liberal use of manures. In twelve months, they become again as barren as they were at first.

A short distance above Richmond are to be seen some specimens of fine granite soils, on the boundaries of the bituminous coal field. On the farms of Thos. M. Randolph and John Wickham, near Tuckahoe creek, where the granite rock, which forms the bed of the coal measures, appears in large quantities, the soil is much more fertile and durable than it is either to the east or west of the granite line. Many years' cultivation, under the usual system, has not impaired its original freshness and vigor. I can only ascribe its superiority over the contiguous cold and heavy lands, to the gradual addition of granite by disintegration; thus constituting a soil in which silicious matter was originally deficient. How far this modification of its texture has been beneficial in other portions of the same range, I have not had the means of judging.

The granite soils which constitute the dividing line between the tertiary and secondary formations of the state, have been represented, and very truly, as being exceedingly barren. If there be no exception to their general character in Virginia, there is, however, a most conspicuous one in the neighboring state of Maryland. The tract of country known by the name of *Elk Ridge*, on the Patapsco river near Baltimore, and which exhibits a soil composed in a great measure of disintegrated granite, is the admiration of all travellers who have seen it. There is perhaps no district east of the mountains which possesses greater natural fertility; nor is there any, where the effects of judicious cultivation are more agreeably exemplified. In approaching tide-water, the character of the soil undergoes a gradual change in proportion to the quantity of decomposed granite.

The low grounds lying on the margin of James River, which are too well known to require any description, may be adduced as an instance of the extreme durability of soils, scarcely less imperishable than the black prairies of Indiana. Though they now exhibit the benefits of good culture in a remarkable degree, even under the severe pressure of the four-shift system; yet the most exhausting tillage to which they were formerly subjected, had effected but little deterioration in their fertility; and indeed some portions of them have never been sufficiently reduced by a long course of corn and tobacco, to yield a crop of wheat that will not lodge before harvest. Their extraordinary productiveness is no doubt chiefly to be ascribed to their alluvial formation, combined with the accumulation of mineral earths which they have received from the mountains through a long course of ages.

The whole of these flats is believed to be now under culture for a considerable distance above Richmond. If there be any remains of the original forest, it is not within my knowledge; but I have a distinct recollection of some portions of it, before it had been despoiled of its glory. Such sylvan magnificence is perhaps no where to be seen in Eastern Virginia at this day; and even the bottoms of the Missouri have seldom exhibited specimens of more towering height and gigantic proportions.

T. S. P.

From Blackwood's "World we Live in."

RAILROADS AND STEAMBOATS.

It might be a serious speculation to inquire into the probable effects of the railroad system on mankind. Certainly no system ever became so popular, and so suddenly and so widely popular. France has begun to fling out those gigantic arms of communication over her noble country. Belgium exults in the commencement of a web of railroad in which it expects to catch all the stray dollars and centimes of the continent. The transit from Ostend to the Rhine will, in the course of a year or two, be an affair of a couple hours. Germany is shaking off the sleep, her blacksmiths are lighting their Hercynian forges, and from the mountains of the Hartz to the Tyrol, huge men with antediluvian visages and Cyclopean arms are hammering at iron wedges, rail, and gear, for "fire horses." Prussia is laying down railroads from her capital to France, to Poland, and to Austria. The puzzling question of her politicians being, whether she thus invites invasion, or proposes defence. But politicians are blockheads on matters of common sense, and of all blockheads the German politician is the most profound, headstrong and hopeless. The merchant, the traveller, and the tinker know better things. They could tell them, that the roughest of royal roughriders, was never able to whip and spur either Frenchman, Belgian, Prussian, or Austrian into belligerency, more than fifty years out of every hundred. But, thanks to the growing common sense of mankind, they never will be able to do this again, now that the world are beginning to discover that fifty years of victory are not worth one year of peace. In short, the world is evidently become a buying and selling world, a vast spinning and weaving community, a vast aggregate of hands and heads, busy about the main chance, and much more inclined to eat, drink, and be happy, than to burn each other's warehouses, or blow out each other's brains. That war will never cease out of the world, is a theorem founded on the fact, that the countless majority of mankind have a strong tendency to be fools; but we may establish another theorem, that the more difficult it is to make war, the less likely it is to be made. The more mechanical dexterity, personal ingenuity, and natural expense that is required to make war, the more will success be out of the power of brute force, and the more in the power of intellectual superiority.

Let war come to a conflict of steam engines and all the barbarian rabble of the world, Turks and Tartars, Arabs and Indians, Africans and Chinese, must obviously be out of the question at once. They may massacre each other, but they must fly from the master of the mechanics. All the half barbarians, Russian, Greek, Pole, Swede and Austrian, must make the attempt only to be shattered, and Field Marshal Stephenson, with his squadron of fire horses, galloping at a rate of eighty miles an hour, must consume their battalia with the breath of his nostrils. Thus England, instead of feeling alarmed at the sudden passion of foreigners for mechanicism, should rejoice to see the passion spreading, should encourage them to throw all their powers into mechanical rivalry, and exult in every railroad that shoots its serpent line among the hills and valleys of the continent, and hail the smoke of every steam engine that trails its murky line along the sky, as not merely an emblem, but an instrument of their own superiority. Mechanicism, the great power of art, is as exhaustless as any of the great powers of nature, for it is only the exhaustless vigor of intellect combining with and commanding the secrets of nature.

Ten thousand years might roll on, and every year see a new advance of every kingdom of Europe in invention, and England keeping ahead of them all, and like one of her own engines, showing her speed by the sparks that lighten the road behind. The steam engine in its effective state, is but little more than half a century old, for its invention, in the time of Charles II., left it upwards of a century, little more than a toy. In half a century more, its present perfection may be looked upon as little else than that of an ingenious plaything. It is scarcely ten years since the steamboat first ventured to sea. Thirty years ago, the late Lord Stanhope, was laughed at by all London, for his attempt to swim the steamboat from London Bridge to Greenwich. It now dashes from the tower to Constantinople; or shoots down the Red Sea, fights the moonshine on its own ground; sweeps to Bombay, Ceylon, and Bengal, and astonishes the Mogul and the Emperor of China, the same morning, with the month's newspapers from London. The railway, in its present power, is not ten years old, yet is already spreading, not merely over Europe, but over the vast savannahs of the New World. What will all this come to in the next fifty years. What must be the effect of this gigantic stride over the ways of this world? What the mighty influence of that mighty communication which, even in its feeblest state, has been in every age, the grand instrument of civilization?

Throw down the smallest barrier to become more civilized. Open the close shut coast of China or Japan to mankind, and from that hour the condition of the people will be in progress of improvement. The barbarian and the despot hate the stranger. Yet for the fullest civilization, freedom, and enjoyment of which earth is capable, the one thing needful is the fullest intercourse of nation with nation, and of man with man.

The European passion for the railroad is certainly one of the most singular, as it is one of the most cheering characteristics of the age. Like all instruments of national power, it may be made an instrument of evil. It may give additional strength to the tyrannical, and accumulate force against the weak, pour resistless invasion against the unprepared, and smite the helpless with unexampled rapidity of ruin. But its faculties are made for peace, its tendency is to make nations feel the value of peace; and unless some other magnificent intention shall come to supersede its use, and obliterate the memory of its services, we cannot suffer ourselves to doubt that the whole system which is now in the course of adoption, with such ardor throughout Europe, will yet be acknowledged as having given the mightiest propulsion to the general improvement of mankind.

From the London Mechanics' Magazine.

EAST INDIA CAOUTCHOUC.

It is well known that a large supply of this valuable substance might be procured from India, if the same care were to be taken in gathering it as in South America. "The London Caoutchouc Company," impressed with this idea, accordingly sent to India an offer of a premium of fifty pounds for the first hundred weight of East India caoutchouc which should be shipped for England. When the offer arrived, however, it was somewhat of the latest, the great demand existing at home for the article had been previously heard of, and large quantities were already on shipboard; compared to which the "hundred weight" stipulated for was but a molehill to a mountain! The whole affair forms an apt illustration of the doctrine that, in commerce, the force of self-interest is far superior to that of artificial bounties.

ORIGIN OF COAL.

Coal is supposed by some writers to be the remains of antediluvian timber which floated in the waters of the deluge until several mineral strata had been formed; others conceive it to be antediluvian peat bog. It was used in England anterior to the reign of Henry III; for that monarch, in 1234, renewed a charter granted by his father to the inhabitants of Newcastle, by which they were permitted to dig coal on the payment of £100 per annum. Coals had been introduced into London before 1306, for in that year the use of them as fuel had been prohibited, from the supposed tendency of their smoke to corrupt the air. About the beginning of the sixteenth century the best coals were sold in London at the rate of 4*s.* 1*d.* per chaldron, and at Newcastle no more than 2*s.* 6*d.* for the same. During the ensuing century, however, they were received into such general use, that in 1648, on the scarcity of coal in London, many of the poor were said to have died from the want of fuel. The whole quantity of coal sent into London on an average of four years, has been estimated at 1,170,000 chaldrons per annum. There has been much dispute on the origin of coal, but Brogniart has given the following as the general conclusions of naturalists:—1. That coal was formed at the same time as, or after the existence of, organized bodies. 2. That this mineral when first formed was liquid, and in a great degree of purity. 3. That the same cause which produces this substance is several times renewed in the same places and under the same circumstances. 4. That the cause, whatever it may be, is nearly the same over all the earth, since the beds of coal always exhibit nearly the same phenomena in their structure and accidental circumstances. 5. That these beds have not been deposited by any violent revolution, but, on the contrary, in the most tranquil manner; since the organized bodies that are found in them are often found entire, and the leaves of vegetables impressed in the slate which covers the coals are hardly ever bruised or otherwise deranged.—*Merthyr Chronicle.*

From the proceedings of the seventh meeting of the British Association, for the advancement of Science.

REMARKABLE CLEARNESS OF THE AIR A PRECURSOR OF RAIN.

Professor Lloyd said that the distinctness and vividness with which distant objects were seen in some states of the atmosphere was quite astonishing: on one occasion he had seen from the neighborhood of Dublin the Welsh hills from their very bases, and brought so near, apparently, that he could absolutely see the larger inequalities of the surface upon sides of the mountains. That the atmosphere was at the time very much loaded with vapor in a highly transparent state, was obvious from the fact, that immediately after a very heavy fall of rain took place, and continued for a considerable time. Professor Stevelly wished to confirm what had fallen from Professor Lloyd and M. de la Rive by stating that whenever the Scotch hills appeared with peculiar vividness and distinctness, from the Lough of Belfast, the fishermen always looked upon it as a sure precursor of heavy rain and wind. A friend had informed him that on one occasion he had noticed this appearance while standing on the beach at Hollywood, and pointed it out to an old fisherman; the old man immediately gave notice to all his friends to whom he had access, who instantly set about drawing up their boats and placing their small craft in more secure places; early the next morning a violent storm came on, which did much damage upon the coast, to those who had not been similarly forewarned. It might, perhaps, be accounted for by supposing that on these occasions the intervening air became actually converted into a large magnifying lens.

From the same.

BEER.

Mr. Black communicated a paper "On the influence of Electricity on the processes of Brewing." According to his statements a thunderstorm not only checks the fermentation of worts, but even raises the gravity of the saccharine fluid, and developes in it an acid. This effect is witnessed principally when the fermenting tun is sunk in moist earth, and may be obviated by placing it upon baked wooden bearers, resting upon dry bricks or wooden piers, so as to effect its insulation. Mr. Black also stated, that during the prevalence of highly electrified clouds, the fabrication of cast iron does not succeed so well as in other states of the atmosphere.

From the Quarterly Journal of Agriculture.

ENAMELLED HARDWARE.

This admirable substance is of German invention, and has only of late years been introduced into the southern part of this country, where it is still but partially known. The art of enamelling on iron, *it is said*, cannot be accomplished by our manufacturers; and we are in a degree disposed to give credence to the assertion; for we know two instances in which potters have given their opinions of the impracticability of its accomplishment. During a visit to London three or four years since, our attention was attracted by some iron saucepans and frying pans, as we passed the shop of an ironmonger at the corner of the Old Bailey, on Ludgate Hill, which appeared as if they were lined with white paper, instead of being tinned in the usual way. On investigation, we found them to be enamelled; and, by inquiry, learnt the following particulars:—That they are imported, a ship-load at a time, from Germany; that the manufacture is unknown in England; that they are durable, and not liable to injure.

We immediately purchased one; and, subsequently, several others of different sizes, as well as a frying pan, and are *entirely satisfied with them all.* We will enumerate their advantages, and our readers will thus judge for themselves, whether or not our panegyric is too highly colored, when we pronounce them to be the *ne plus ultra* of cooking utensils,—without a fault! They are kept clean with the least possible trouble; they never crack or craze, and they perfectly retain the color and the flavor of every product of the culinary art; so many sad accidents have resulted, and are still occurring, from the use of copper saucepans, stew-pans, &c., that it becomes a duty, with every writer of influence, to dissuade the public from the use of them, by urging the deleterious nature of copper on their attention. To our readers, we are well aware, this information will be superfluous; but they must know, as well as ourselves, that errors remain unrectified,—abuses exist unabated—faults rest unreproved—dangers lurk and threaten uncared for, until our natural supineness is roused by an actual evil overtaking us, which might and ought to have been prevented from existing. When too late to avert a calamity, we wonder at our apathy, and bewail our culpable remissness. Gentlemen are out of the sphere of copper stew-pans, and provided they find their dinners well appointed, care nought for the kind of metal in which they are cooked; domestic matters being very properly consigned to the lady of the establishment. But it unfortunately happens, that ladies dislike to interfere, and rely upon the sagacity of their housekeepers, who also depend upon the cleanliness of their subordinate kitchen-maids; and thus may the lives of a whole household be periled by the ignorance or idleness of this denizen of the scullery, as yet unvisited by "divine philosophy." We can well imagine, that on reaching this period of our subject, some "lord of a wide domain" looking off from his "Quarterly Journal," will address his lady with this startling question, "Are there any copper stew-pans or sauce-pans in the kitchens, my love?" To which she will, with unfeigned surprise, reply, "Really, my dear, I not know, but I dare say Harris can inform you;" and the affair of poison in a ragôut being momentous, the housekeeper would be summoned, and be in turn astonished with a similar query. Her reply of "Yes, at least a dozen," would complete the incipient dismay; and an order to have the dangerous utensils abolished, with the reason assigned, would infallibly elicit a decided assurance on the part of the confidential servant, that "all stews *must* be made in copper, for iron, tinned, would impart a flavor; that preserves and pickles *must* be boiled in copper, because they would lose all color, and not be fit to be placed on table, if iron was to be substituted."

This imperative "*must*" would, alas! in too many cases, decide the matter, and that vile pernicious copper still bear sway in the kitchens. In these admirable German stew-pans, however, we have a succedaneum of unquestionable capabilities, to supersede the necessity of pleasing our eye at the risk of our lives. Every species of cooking has been performed in our own utensils for several years, and to far greater perfection than we ever experienced, previously to the introduction of the enamelled hardware. Independently of its salubrity, we should give it the preference over every other; for, in consequence of the delicate and innocent nature of the glaze, which resembles that of china, all color and flavor are preserved in their utmost purity; and all housewives are aware, that these are desiderata in pickling and preserving.

We have stated that this ware is not liable to injure; but we ought to have placed this essential advantage in much more forcible language. The union of the enamel with the iron is so intimate, they are so entirely amalgamated, that it is utterly impossible to effect a separation; and we have known, that in the attempt several iron tools have been broken.

If we knew of a fault in them we would gladly name it, not only as a guide to ourselves in our future purchases, but because our readers would, perhaps, trust rather to qualified than unqualified praise. The only drawback which we ever found, was in their weight, which was greater than those made in England of the same size, and perhaps a dissightliness in the forms compared with those of our own manufacture; but both of these trifling objections have recently been removed. We confess that we had migivings when we made up our mind to order a frying-pan, that the enamel would not endure the very great heat to which that kind of cooking necessarily subjects the vehicle in which it is performed; but we are gratified in being able to assert, that we have had one in frequent use for some months past, and it is as white and uninjured as when we received it first.

We should rejoice to hear that our manufacturers intend to give their attention to this useful and beautiful art; and what can they not achieve with that industry, perseverance, science, wealth, and emulation, for which they are, above those of all other nations, celebrated?

From the Gardeners' Magazine.

CONJECTURES RESPECTING THE CAUSES WHICH PRODUCE DOUBLE FLOWERS IN PLANTS; TOGETHER WITH THE RESULTS OF SOME EXPERIMENTS MADE WITH A VIEW TO THE SAME OBJECT.

By James Munro, Forester to the Marquess of Northampton, at Castle Ashby, Northamptonshire.

Of the various phenomena which nature exhibits in her economy of the vegetable kingdom, the cause which produces double flowers, and other singular varieties of plants, is, perhaps, least understood by horticulturists. Different reasons have been assigned for the presence of this *lusus naturæ* among vegetables; but, when even these theories have been subjected to a practical test, disappointment has followed.

The prevailing opinion, in earlier times, rested on the theory of contact; in other words, that double-flowering plants were a result from single and double plants of the same kind growing near to each other; an erroneous assumption, that double flowers possess impregnative qualities. Any person, possessing the slightest knowledge of the sexual system of plants, knows that double flowers are destitute of the productive organs; consequently, no seed can be obtained from plants of this description: they are anti-natural, and are occasioned by some infringement of the laws which regulate the vegetable economy. How, then, is it possible that plants thus physically incapacitated for self-reproduction, by seminal process, can influence the character of their neighbors by the mere circumstance of proximity? Besides, the unalterable relation of the order of cause and effect is fatal to this theory; for, if the agency of double flowers is required to alter the quality of single-flowering plants of any kind, the question arises, By what means did such flowers come to exist at first?

Of late years, it has been stated that Dr. Graham of Edinburgh gave it as his opinion, that, in order to have double stocks, it is only necessary to sow and rear the plants upon an exceedingly rich soil, such as the pulverised material of old hotbeds, &c. By this mode of treatment, I suppose it is presumed that the plants shall receive such a surfeit of alimentary matter as will cause a departure from the natural way by which their various organs are formed, and their functions regulated. The high authority whence this theory was said to emanate secured it from me a fair trial; but the experiment failed completely. My after experience points out a cause of treatment the opposite to that of Dr. Graham. I have found that, the more plants intended to save seed from are checked in their luxuriance, the greater is the chance of success. Every florist must have observed that all the stunted-growing kinds of annual stock are more productive of double flowers than are the rambling-growing sorts; and that, in both cases, the proportion of doubles is greater from seed that is saved in an exceedingly dry season, when the growth is less luxuriant. From this and other circumstances which have come under my notice, I think there are grounds for questioning whether the agency of any of the afore-mentioned theories is in the remotest degree connected with the producing of double blossoms.

The longer I consider this subject, the less I feel disposed to trust in the efficacy either of the theory of contact or of alimentary surfeit; the true cause, I think, is more likely to be detected by properly tracing that striking analogy which subsists between vegetable and animal creation. This analogy is stronger than is generally supposed; and, therefore, if we would arrive at correct conclusions regarding vegetable physiology, we would do well to keep constantly in view the relative position which the subjects under consideration may occupy in the scale of creation. Plants are dependent on air and nutriment as well as animals: they are furnished with numerous organs, suited almost to an animated existence; these are skin, pores, glands, hairs, bristles, flesh, or fibre: they have organs for respiration, with veins and arteries, and a circulating fluid traverses the whole. This fluid is at times held in excess by some trees; when bleeding, or an operation equivalent thereto, may be practised with propriety. Ringing the bark of fruit trees, and shortening their roots to bring them into bearing, are here alluded to; by which process, if a copious discharge is not effected visibly, still a determination of sap to the head is prevented: this fluid adds annually to the bulk and strength of the vegetable structure; which, as with animals, the better it is fed, the better it flourishes. Nor does the analogy stop here: mutilations may be healed or replaced; wounds and bruises may be cured by applications similar to those remedies resorted to in cases of fractures of the animal frame. Cancerous substances and tumorous excrescences may be excavated from trees as from animals; and counter-irritations are successfully employed by gardeners, many of whom well know the advantage of this process on trees technically termed hide-bound. Slitting open the bark, in such cases, produces effects on trees similar to that of the blister on animals. It has likewise been affirmed that excrementitious matter is emitted from the roots; and scrofulous-looking tumors, on some trees at least, are common.

If due consideration be allowed to all these close resemblances which the vegetable creation bears to the animal, I trust I shall not be thought extravagant in my ideas, if I endeavor to account for the phenomena of vegetable variation by tracing that analogy a step farther, and assign to plants, as in animals, a plurality of fluidal systems. In animals, the different fluids and humors originate in one common source, the blood; in plants, each system seems to have a direct communication with the elements, and in their operations are independent of each other. It is evident, from the manner in which its operations are conducted, that there is one grand system employed in forming the bark, leaves, and woody fibre; viz., the albuminous current: it is also apparent that a separate system exists in plants for the perfecting of the fruit, which may be denominated the seminal fluid; and it is highly probable that these systems are of a compound nature, each, perhaps, furnished with organs for producing the properties of color, taste, and smell, peculiar to each division. If the progress of vegetation is watched closely, we find that every tree, according to its kind, if raised in the natural way (that is, from the seed), has its whole powers directed to the accumulation of wood, bark, and leaves, for a series of years. Twelve years commonly elapse before the fruit-buds appear on the apple. In form and size, these buds differ so widely in appearance from the buds which produce the annual spray, that the most partial observer must conclude that they cannot be the work of one and the same agent: if it were so, the fruit-buds, of course, would be contemporary with those that produce wood; this is sometimes the case with grafted trees, but never with such as are raised from the seed. If one universal system of fluid in plants (a servant of all-work) is contended for, viz. the albuminous current, how are we to account for its extremely eccentric nature? To suppose that it possesses the faculty of communicating color, taste, and smell to the wood, bark, and leaves, of a peculiar description, whilst it supplies the flower and fruit with these properties of a totally different description, is preposterous. In its journey through the leaves, the alburnous fluid must, doubtless, all undergo the same process of elaboration; consequently, must possess a unity of character: the whole mass must be applicable to one purpose only, either for the creation of bark, wood and leaves, or of flowers and fruit. It cannot be credited, that the same agent that gives to the capsicum stem and leaves the green color and insipid taste, is capable of communicating the inveterate acrimony of taste to the seed, and high color to the capsule. For my own part, I can see no way of overcoming the difficulty of accounting for the difference of color, taste, and smell, held respectively by what I shall here designate as the two grand divisions of the vegetable structure, except a plurality of fluidal systems be admitted. In short, the fact that these properties can be affected by the manner in which a plant is treated, is conclusive: color, in particular, may be altered by treatment, without interfering with any of the other properties; a fact clearly demonstrative of the independent action of the different systems.

There are many other facts which might be brought to bear upon this interesting subject; and I may particularise the dahlia as constituting a lucid example. Strictly speaking, the dahlia is not a double-flowering plant; still, I affirm that no plant ever introduced into our British gardens has been so rapidly improved. Great are the changes that have been effected in the color, size, and form of its flowers; still the stem and leaves have kept a uniform similarity, differing but little in appearance since the day of its introduction; a fact clearly proving that one of the grand divisions of the fluidal systems in plants may be affected by foreign influence, without detriment to the others. The improved condition of the dahlia, in regard to its flowers, I do not consider to be a consequence either of contact or of alimentary surfeit; but that it owes its origin to treatment in accordance with the theory herein contended for. Competitors at dahlia exhibitions, from observation, have learned the propriety of preventing an excessive bloom on their best sorts, seldom permitting more than three or four of the flowers to expand. By this means the sphere of the seminal fluid is curtailed, and the excess thus produced, acting upon a concentrated field of operation, undoubtedly causes the departure of the progeny from the habit of the parent: whereas, if the whole of the flowers which appear upon a plant were permitted to expand successively, the seminal fluid would then be equally distributed, in such proportion to each seed as would accomplish the intentions of nature; namely, consentient reproduction. The following experiment, performed by me some years since, is so strongly corroborative of what is here advanced, that I cannot resist giving it in brief detail.

At that period, I had a quantity of single scarlet ten-week stocks. Impressed with the belief that my theory was worth a trial, I selected a number of the plants; and, as soon as I observed five or six seed-pods fairly formed on the flower spike, every succeeding flower was pinched off. From the seed saved in this manner I had more than four hundred doubles on one small bed. Whether this success was in consequence of my mode of treatment, remains to be proved by future experiments; yet I cannot help thinking that it was; and that, if I had left fewer seed-pods on the spikes, the proportion of double plants would have been still greater.

In conclusion, I shall instance one or two more facts in favor of this theory, which are acted on almost every day: I allude to thinning of grapes, peaches, and other fruits; a process whereby the quality of fruit is much improved, while the woody part of the plant is not visibly affected. If the albuminous current were alike the source of woody fibre and fruit, any operation tending to produce immediate improvement on the one would, as a matter of course, be observable on the other: this, however, is not the case. Again, when a tree shows any decided determination to fruit bearing, little or no spray-wood is made; on the contrary, when an inclination to wood is exhibited, fruit is less plentiful: circumstances clearly proving that in vegetables there do exist two principles, and, to a certain extent, opposed to each other. It is in consequence of the contention of these principles, that practical men resort to ringing of the bark, shortening of the roots, &c., as remedies bearing the sanction of experience, for counteracting any ascendency which the one may have obtained over the other. I shall only add, that the experience which I have had of the working of this theory has determined me to resume my experiments on the first opportunity, the results of which shall be faithfully communicated.

Castle Ashby, Dec. 1837.

From the Franklin Farmer.

HARVESTING OF CORN.

To the Editor.—As the season is approaching in which the farmers will commence the securing the abundant crop of corn with which a bountiful Providence has blessed our country, it may be pertinent to the occasion to offer a few remarks upon the best mode of harvesting the crop.

Our Virginia ancestors and those who think it wise to plant and cultivate and gather as our fathers have done, pursue the old method; about this time they gather the blades below the ears of corn—after they consider the corn to be ripe, they top the stalks and secure all of the fodder in stacks for winter use. In November they pull the corn and remove it to cribs, where it is husked out at leisure. This mode is rapidly yielding in the stock districts to that first introduced among the graziers on the south branch of the Potomac. The farmers in the northern and middle districts of Kentucky, and in the Scioto valley of Ohio, have generally adopted this latter mode; which is to cut the stalks, corn, fodder and all, and place them in shocks commonly embracing sixteen hills square.

I have seen the richest crops of many climates gathered, and there is no operation in husbandry so animating as that of cutting corn in the mode just mentioned. It is a most cheering prospect to see twenty acres of corn pass in one or two days to a condition in which it is prepared to keep in the field throughout the winter. This remark is predicated particularly upon the plan of riddling the squares, instead of cutting the whole square at once. It will readily occur to any observing mind, that as corn does not ripen with precise regularity, if the entire square is cut out at once, some of the corn will mould and sometimes even the fodder will be affected, if the cutting shall be followed by warm or wet weather. To avoid this contingency, some graziers commence with the process of riddling, that is, they select only such part of the sixteen hills square as may be ripe—go through the field in this way, and in ten days complete the cutting of the square. By this process several important advantages are obtained—the greatest amount of fodder is secured, consistantly with the paramount object of saving the corn, and a nucleus for the shock being formed by the first cutting in the square, the shock becomes settled and stands better during the winter. In the rich counties of Clarke and Bourbon, they sometimes cut half of the square on one side and then in ten days finish it. Whilst many graziers in Fayette, Lincoln and Shelby, prefer the process of riddling.

In the course of October and November, these shocks are shucked out, the corn placed in cribs and two of the shocks placed together, or one placed upon the ground and two others put around it.

It is the opinion of practical farmers, that the practice of cutting corn in this mode secures the greatest amount of corn and fodder with the least expense, and is decidedly an improvement on the old Virginia plan, more especially when applied to the feeding of cattle or mules. T.

From the Quarterly Journal of Agriculture.

ORGANIZATION AND FUNCTIONS OF ANIMALS AND VEGETABLES COMPARED.

It is a very important preliminary to the study for which I would gain the attention of practical men, that they understand the nature of plants; of those organic creatures whose diseases they would obviate; for an ignorance of, or an inattention to this, is one of the causes that so little progress has been made in this branch of natural philosophy. It is absolutely necessary and important for them to understand fully that this part of the creation, the very grass they trample upon, is so highly organized, so exhibiting intimations of the functions more highly developed in the superior animals, that it is not possible to point out where animal life terminates, and where vegetable life begins: the zoophyte connects the two kingdoms. It is absolutely necessary, I think, for this to be understood and felt by those who enter upon the investigation of vegetable diseases, because I have a strong opinion that these in many, very many instances, are caused by the plants which they infect being treated as if they were totally insensible, inorganic matters, scarcely more susceptible of injury at some periods of their growth than the soil from whence they partly derive their sustenance.

To determine the question whether plants possess a degree of sensation, is not so easy as many persons may believe. "It is as difficult," says Mr. Tupper, who has written ably upon the subject, "to ascertain the nature of vegetable existence, as to determine what constitutes the living principle in animals." Darwin, by the aid of imaginary beings similar to the Dryads and Harmadryads of the classic mythology, has raised plants to a position in the order of nature superior to that to which animals are entitled. Other philosophers, taking a totally antagonist opinion, estimate vegetables as bodies, only somewhat more organized than crystals, but like these entirely and exclusively subject to chemical and mechanical changes.

The above opinions are equally erroneous, as will appear from the facts arranged in the following pages. It might easily be made to appear that the gradation from reason to instinct, from instinct to inanimation, is as gradual as the transitions of light from the noon-tide to the midnight of a summer's day; but this essay must be confined to that section of creation that commences from the close of the animal classes in the zoophyte, and terminates where inorganic matter commences in the crystal; and its details must be specially directed to demonstrate how closely it approaches, how indistinctly it is divided from the former.

Let us first consider the comparative composition of animals and plants demonstrated by the researches of chemists. Their constituents are identical: carbon, hydrogen, oxygen, nitrogen, sulphur, phosphorus; acids, alkalies, earths, and metals, are the common components of both. Nitrogen has been considered by some chemists as the constituent, marking by its presence animal from vegetable matters, but the distinction fails in as much as that from some animal matters it is absent; whilst in the gluten of plants, a chief constituent of wheat, and in the whole frame of the tobacco, it is present.

If we follow the above chemical bodies through their combinations, we shall find that these in animals and plants are closely similar; and in both are equally numerous and intricate.

Of the acids there are contained in

Animals.	*Vegetables.*
1. Sulphuric,	1. Sulphuric,
2. Phosphoric,	2. Phosphoric,
3. Muriatic,	3. Muriatic,
4. Carbonic,	4. Carbonic,
5. Benzoic,	5. Benzoic,
6. Oxalic,	6. Oxalic,
7. Acetic,	7. Acetic,
8. Malic,	8. Malic,

and others equally numerous in each, but not common to both. Of the earths and alkalies, lime, magnesia, silica, soda, and potass, are found in each class. Of the metals, iron and manganese are their conjoint constituents.

If we follow the two classes through their more compound constituents, we will find the analogy still holds: they contain common sugar, mucus, jelly, coloring, and other principles, gluten,* fibrin, oils, resins, and extractives. The functions of animals and plants are similarly closely analogous.

Animals take in their food by the agency of the mouth, and prepare it for digestion by various degrees of mastication, or attrition, as in the gizzard of birds. In this they differ from plants, but these have this compensation, they imbibe their food in a liquid form, and consequently in a state of the finest possible division. Animal and vegetable remains are their common food, plants having this superiority over animals, that, as they only absorb the soluble and finer parts, they are not obliged to throw off the grosser constituents which appear in the excrement of animals.† In the animal stomach the food undergoes an extensive change, being reduced to a pulp of greater specific gravity, and being altered entirely both in taste and smell. In the lymphatics of plants, which may be considered their primary organ of digestion, their food, or lymph, undergoes a change precisely similar; its color and flavor are altered, and its specific gravity increased.

From the stomach, the animal's food passes into the intestines, is there subjected to the action of the bile, and converted into chyle, the nutritive part, and excrementitious matter. In their passage through the intestines, the chyle is absorbed by the lacteal vessels, and is conveyed into the blood; by the heart, the mingled fluids are propelled into the lungs, to be there exposed to the action of the air. The vital fluid there changes its purple hue for a florid red, loses a portion of its watery particles and carbon; the latter combining with the oxygen of the atmospheric air in the lungs, and being breathed forth in the form of carbonic acid gas. As plants in their food take in no gross, unnecessary ingredients, it is obvious that no process like the biliary operation of digestion is required. The lymph, or sap, proceeding at once along the branches, is poured into the leaves, the very lungs of plants. There, as in the blood, its color is changed, oxygen is emitted from it during the light hours of the day; but carbonic acid gas is thrown off during the night, and at all periods a considerable quantity of water.

From the lungs, by the agency of the heart, the blood is propelled through the arteries over the whole animal system, supplying nourishment and warmth to all the parts, and where, by these abstractions, it is again converted into purple or venous blood, it is returned by the veins to undergo the changes that were described as being effected by the lungs.

The sap, after exposure to the action of the air in the leaves, is returned by another set of vessels situated in the bark, ministering to the growth and support of the whole plant.

Such is the close assimilarity in the digestive and circulatory processes of the two classes; an assimilarity which obtains in all the other functions enjoyed by them in common. In respiration, the air inhaled through the mouth and nostrils proceeds immediately to the lungs and acts upon the blood; in plants, when it is inhaled by their leaves, it operates instantaneously upon the sap. The changes that take place have just been imperfectly noticed; but it is necessary to add, that the oxygen of the atmosphere, is the gas essential to the existence of animals; but it is its carbonic acid that is nearly as important to vegetables. They may be considered the vital airs of the two classes. If animals are placed in a situation where they inhale pure oxygen, their functions are highly and rapidly increased; but it is an exhilaration which would soon terminate in exhaustion and death, if breathed by them for any extended period. So plants will flourish in an atmosphere containing $\frac{1}{12}$th of carbonic acid, but if it much exceeds this proportion, they are rapidly destroyed. During sleep, animals expire less carbonic acid than during their waking hours; so plants emit little or no oxygen during the night.

After an animal has enjoyed the regular course of its functions for a period varying in its duration, the time at length arrives when decay commences. The wasted, enfeebled, and relaxed form gradually declines, until death finally closes all activity. The body then becomes contracted and rigid; the skin exchanges the ruddy tinge of health for death's pallid hue. Decomposition speedily ensues, with all its offensive phenomena; and finally the only permanent remains are the skeleton and a small amount of earthy matter. The same characteristics attend the last period of vegetable existence. Plants may flourish only for one season, or their lives may be extended through centuries of years, yet decay eventually comes over them; becoming more and more stunted, weak, pallid, and ragged, they eventually cease to live, become contracted and rigid, and pass through the same phases of putrefaction that are exhibited by the animal carcass. In both there was a time when warmth and exposure to the atmosphere were the sources of vigor, they now become the agents of destruction; they were once able to resist and to overcome the laws of chemical affinity, they now are destroyed by their attacks. What causes this most striking change? What antiseptic agent have they lost? There can be but one reply. It was their vitality. Now, let us examine how the vitality of plants in other respects resembles the vitality of animals, and I will confine this examination to two or three points.

Plants are *excitable.* Light acts upon them as a stimulus. Every body must have observed that plants bend towards the direction from whence its brightest influence proceeds. M. Bonnet, the French botanist, demonstrated this in some very satisfactory experiments, by which he showed that plants grown in a dark cellar, all extended themselves towards a small orifice admitting a few rays of light. Every flower almost has a particular degree of light requisite for its full expansion. The blossoms of the pea, and of other papilionaceous plants, spread out their wings in fine weather, to admit the solar rays, and again close them at the approach of night. Plants requiring a powerful stimulus, do not expand their flowers until noon, whilst some would be destroyed if compelled to open in the meridian sun,—the night-blooming *Cereus* unfolds its flowers only at night. Heat also acts as a stimulus upon plants.

* The gluten of plants is the albumen of animals.

† Is not the excretion from the roots of plants, as proved to exist by M. De Candolle, somewhat analogous to the excrementitious matter of animals?—EDITOR.

M. Duhamel observed, that during moderately fine weather the footstalk of a leaf of the sensitive plant *(mimosa pudica)* stood in the morning at an angle with the lower part of the stem of 100°; at noon the angle had increased to 112°, but at night had fallen to 90°. If a leaflet of this plant be but slightly touched, it immediately shrinks away; and the impulse being communicated, each pair of leaflets on the branch collapse in succession; and if the impulse be strong, the very branch itself will sink down by the side of the stem. If an insect alight upon the upper surface of the Venus's fly-trap, *(dionæamuscipula,)* its sides spasmodically approach each other, and crush to death the intruder. If the inner side, near the base, of any one of the anthers of the barberry, *(berberis vulgaris)* be gently touched, as with a bristle or feather, it instantly springs forward and strikes against the stigma. But the strongest indication, says Mr. Keith, of the existence of a species of sensitive principle in a plant, is, perhaps, that which is exhibited by the *hedysarum gyrans*. It is a native of India, growing on the banks of the Ganges. Its leaves are ternate, the middle leaflet being larger than the lateral ones. All of them are in constant vibratory motion; sometimes equably, at other times abruptly, but without any unison in the movements. If their motion be prevented, by grasping them in the hand, they renew it more vigorously when the confinement is removed, but by degrees subside to their natural rapidity of motion. This motion does not depend upon the application of any external stimulus, for it continues throughout the night as well as the day. It is most active during a warm fine day, the leaves then having an additional tremulous motion. *(Keith's System of Physiological Botany*, ii. 464.)

Instinct seems to be a characteristic of plants, from the following phenomena. Some of them close their flowers invariably when rain is approaching. Others have an unalterable direction assumed by them when climbing. No force can make one twist round a pole from left to right, if its natural direction be from right to left. If a garden pot be divided by a vertical partition, and one-half filled with a poor steril earth, and the other moiety filled with a rich fertile soil, a geranium or other plant placed in this pot, with some of its roots over the steril soil, and the rest of the roots over the fertile soil, those over the first named portion will gradually change their direction until they can also get into the richer pasturage. Instances have been known of the roots of trees piercing and destroying walls in their efforts to attain a more preferable soil than that in which they were planted. M. Saussure relates, that he placed some plants of *polygonum persicaria* and *bidens cannabina*, in water containing acetate of lime in solution. These plants then imbibed with the water a portion of this salt; but when they had the opportunity of selection given them, by dissolving in the water some common salt, glauber salt, and acetate of lime, they absorbed the two first named, but rejected the latter entirely. *(Saussure's Recherches*, 247-261.)

From the foregoing facts, without arguing that they demonstrate sensation to exist in plants as acute as that possessed by the higher or more perfect classes of animals, yet they certainly are satisfactory evidence that plants probably are nearly as sentient as the zoophyte, or even as the polypus and the hirudo,—animals that may be cut into pieces, and each section become a perfect individual,—animals whose heads may be taken off and grafted upon other bodies,—animals that may be turned with their outsides inwards, and yet without any apparent inconvenience. If plants be endowed with sensation of the most limited degree, it explains the cause, throws light upon the prevention of many diseases that affect those which are the object of cultivation, warns the tiller of the soils from the late performance of many of his operations, and teaches him generally to be less violent in his field practice. If a grape vine be pruned too late in the spring, the bleeding, or effusion of sap, has been known to be so violent, that the tree has died from absolute exhaustion. Stone fruits, if severely wounded, are frequently destroyed by the inroads of a disease resembling in all its characteristics the cancerous affections of animals; and I have known a whole crop of wheat affected with a swelling of the stem or culm, evidently caused by an extravasation of the sap from its ruptured internal vessels, owing to the roller being passed over the crop when of a growth somewhat too forward.

From the proceedings of the seventh meeting of the British Association, for the advancement of Science.

CATASTROPHE IN A MINE.

Mr. Sedgwick requested the attention of the meeting to an account, which he was about to submit, of the late unfortunate accident at the Workington Colleries. He pointed out, on the geological map, the rocks which occur in that neighborhood, and stated some of the phenomena of the stratification of the coal measures, which are there very much disturbed. There is an anticlinal line, on the opposite sides of which the strata dip differently, so that, in one place, very important beds of coal crop out under the sea. Workings, quite submarine, have accordingly been carried on for some time: in the Isabella pit, a depth of one hundred and thirty-five fathoms under high water has been reached. A culpable want of caution has been shown by the managers of late, as they have caused the workings to reach too near the sea—even within fourteen fathoms of it; and the pillars and roof of the older works had been taken away, by which the danger was greatly increased. There had been repeated warning from the shrinking of the ground, and from an old work having become filled with water; also in the new workings—although the pumping brought up one thousand gallons per minute, the miners were in such danger of being drowned, that several left the employment. In the latter end of July, the sea at length broke in, filling the mine in all its parts, in little more than two hours, and destroying twenty miles of railway. On one side of the Camperdown Dike, which ranges through the mine, not a soul was saved; but several escaped from other parts, and one individual, an Irishman, called Brennagh, had not only a remarkable escape himself, but saved three others by his intrepidity. Professor Sedgwick related to the Section this man's story, which was so singular and told with such a mixture of the serious and ludicrous—often in the language of the man himself—that it is impossible to convey to the reader an idea of the effect produced on the audience. A remarkable fact in the escape of one of the individuals rescued by Brennagh was, that he was actually *blown up* the last open shaft of the mine by the enormous force of the air, the noise of which was heard at a considerable distance in the country. The first notice to Brennagh of the accident, was an unusual undulation of air in the galleries, which made him suspect that all was not right, and he took the precaution of moving near to an air passage in the dike, which he had been permitted to use: he was thus enabled to save himself and his companions. At the suggestion of the professor, a subscription was made in the Section for Brennagh, which amounted to £34.

From the same.

PLANTS GROWING UNDER GLASS.

In April last, Dr. Daubeny introduced into globular glass vessels, their aperture being covered with bladders, three several sets of plants. In the first were *sedum, lobelia, &c.*; in the second, *primula, alchemilla, &c.*; in the third, *armeria, sempervivum, &c.* At the end of ten days the plants were healthy, and had grown. The air in the jars was examined, when it was found that the first had four per cent. more oxygen than the atmosphere. the second also four per cent. more, and the third one per cent. more. This was the result of examination during the day, but at night the excess of oxygen had disappeared. On the eleventh day, the first jar contained two per cent., the second and third, one per cent. excess of oxygen. At night there was less oxygen than in the atmosphere. On the 20th of June, the following results were obtained: in the first jar, two and a half per cent., in the second jar, three and a quarter per cent., and in the third jar, four per cent. less oxygen than in atmospheric air. Some experiments were then made to determine the rate of success of air to the plants through the bladder, and it was found that when the jars were filled with oxygen, the average rate at which it escaped till the internal air was like that of the atmosphere, was eleven per cent. daily.

Professor Lindley then read a paper by Mr. Ward on the same subject. The professor observed, that Mr. Ward, of Wellclose Square, London, had made many experiments on the subject of keeping plants in unventilated vessels, and was the original proposer of the plan for preserving plants in this manner. The discovery of their being able to be thus preserved, was of great practical importance, as it enabled us to bring plants from foreign climates, that could in no other way be introduced into this country. The paper commenced "consider the lilies *how* they grow." The attention of the author was first directed to this point by accident. He had placed under an inverted jar, a chrysalis, and on looking at it some time after, he found a fern and a blade or two of grass had grown under the jar, the sides of which appeared to be covered with moisture. Taking the hint, he introduced some plants of hymenophyllum under a jar, which grew and flourished in this situation. The Messrs. Loddige then enabled him to perform some experiments on a larger scale. The plants were enclosed in glass cases, or small green-houses, made tight with paint and putty, but, of course, not hermetically sealed, and were watered once in five or six weeks. From his experiments, the author came to the following conclusions: First, that confining the air secured a more equable temperature for plants, as its expansion and contraction by change of external temperature, by its relation to heat in those states, prevented any great or sudden change. This was remarkably exemplified in some plants that were brought from India, which were in the course of three months successively exposed to 20°, 120°, and 40° of Fahrenheit. The enclosed plants were very frequently found surrounded by a temperature higher than the external atmosphere. Secondly, that vascular plants required to be grown in a greater quantity of air than cellular. Thirdly, that the light must be freely admitted. Fourthly, that the enclosed air must be kept humid. This can be done by occasional watering, provided any means of escape for the water is allowed, but is not necessary where the water has no means of escape. Besides the advantage of enabling us to bring plants from abroad, it would also furnish to the physiological botanist the means of observing those operations of nature in his study, for which, before, he had been obliged to resort to the forest and the plain. As an instance, the author had been enabled to observe the rapid growth of a *phallus fœtidus*, by merely devoting to it a few hours of the night. The writer concluded by suggesting that this mode of preserving tropical productions might be extended from the vegetable to the animal kingdom.

Professor Lindley also read a letter from the Messrs. Loddige to Mr. Ward, stating that in every case in which his instructions had been attended to, foreign plants had arrived in a state of safety.

The Rev. J. Yates read a paper on the same subject. Wishing, he observed, to make an experiment, on a large scale, which might be exhibited at the meeting of the British Association in Liverpool, a green-house, nine feet by eighteen in dimensions, and with a southern aspect, had been erected in the yard of the Mechanics' Institute, in Mount-Street. It was stocked with foreign plants, of all kinds, to the number of about eighty species. A list of the plants, and observations on their condition and progress, accompanied the report. The general result of the experiment was, that the plants had flourished perfectly well, being in a vigorous and healthy state, without any extraordinary growth. Many of them had flowered, and canna and some ferns had ripened seed. The green-house had no flue, and no provision for any artificial heat. It was judged best to construct it without a flue, both as least expensive, and for the purpose of trying, by a fair experiment, to what extent plants might in this state be kept alive, even during the severity of winter, which would certainly die if fresh air were more freely admitted. It was also to be observed, that nothing had been done to prevent the water from escaping through the yellow sandstone rock, on which the green-house was erected, and hence it had been necessary to give the plants occasionally a fresh supply of water. Mr. Yates further stated, that he had also grown plants under glass in London, where no plant could be made to flourish without such a protection. Nearly a year ago he planted *lycopodium denticulatum* in a chemical preparation glass, with a ground stopper. During that time the bottle has never been opened; yet the lycopodium continues perfectly healthy, and has grown very much, although, for want of space, the form of the plant is distorted. Seeds which happened to be in the soil have germinated, and marchantia has grown of itself within the glass. He also obtained a a hollow glass globe of eighteen inches diameter, and with an aperture sufficient to admit the hand for planting the specimens. A variety of ferns and lycopodiums were then set in the soil, which was properly moistened with water. This having been done, the aperture was covered with sheet India-rubber, its attachment to the glass being made perfectly air-tight. No change of air could take place, except by percolation through the India-rubber, which was every day forced either outwards, as the air within the glass was heated and expanded, or inwards in the reverse circumstance; these ferns grew probably as well as they would have done in a green-house, or hot-house. They were all foreign, and some of them requiring great heat. Several had ripened seed.

Mr. Gray stated, that he had grown droseras under glass jars; one circumstance with regard to them he thought worthy of remark, their leaves did not turn red, as is usual when exposed to the atmosphere. Professor Graham observed, that although in Mr. Ward's experiments atmospheric air had been admitted, he did not think it essential to the welfare of the plant. Plants grown in this manner only required a glass large enough to contain a sufficient quantity of air, to permit of the absorption of oxygen without deteriorating the air of the vessel to such an extent as to injure the plant. The want of red in the leaves of drosera, he thought, depended on the presence of moisture. A singular point was, that plants growing naturally in arid soils and climates, flourished in the humid and confined atmosphere of the closed jars. He had placed under jars completely closed some plants of cacti, which had flourished more than those not so situated. He did not think that animals could be sustained in the same manner, as they consumed all the oxygen which they inspired. Dr. Travers remarked, that he had seen common mould, which was a species of fungus, in a tube which had been heated and hermetically sealed for two years. Mr. Bowman had observed at the Duke of Devonshire's, Chatsworth, that droseras did not, under the jars, change the color of their leaves as in open air. He wished to know of Dr. Graham, how long his cacti had lived in a moist atmosphere; they were naturally, at certain seasons of the year, exposed to heavy rains. He thought it was very possible for plants and animals to live together. Mr. Duncan inquired if plants were healthy, and fit to be transplanted to the open air, when treated in this manner. Professor Graham stated, that the cacti had lived without access to air eighteen months. He believed that plants and animals might live together, provided the vessel in which they were inclosed was sufficiently large to enable the plants to absorb the carbonic acid gas, expired by the animals. This would be a representation in miniature of what takes place in our own world. Professor Lindley, in reply to Mr. Bowman's question, stated, that plants suffered little when confined in carefully closed vessels. From improper treatment they may become debilitated, but he had seen them arrive from foreign countries, when treated in this manner, in the most perfect state of health. Want of skill in the management of those brought from abroad was the most frequent cause of injury. Too much water was frequently given to plants when just packed. They had better be placed in too dry, than in too moist an atmosphere. He had seen this illustrated in plants from India; plants exposed to too much moisture rotted very soon. He thought the change of color in the leaves of plants depended on their free exposure to light; the droseras mentioned, had not been exposed to the free access of light; this was certainly the case with the droseras at Chatsworth and of Mr. Gray. The discovery of Mr. Ward was not only important in enabling us to import foreign plants, but it also rendered the ventilation of green-houses less necessary, and would enable gardeners to manage the artificial climate of their hot-houses with less difficulty. The fact that cellular plants grow best under this mode of treatment, was well established. In answer to a question from Professor Lindley, Mr. Gray and Mr. Yates stated, that plants had both flowered and fruited under this plan of treatment. Professor Graham stated that the order in which he had found plants to grow best, was: 1. Lycopodiums; 2. Grasses; and 3. Begonias.

LIME AS MANURE.

We are pleased in laying before our readers the following valuable communication of Judge Hayes, as he is considered one of the best farmers in the country, and his experience will be valuable to others. His beautiful and productive farm gives evidence that the hand of industry is directed by intelligence. Other communications from the same source will be very acceptable.—*Yankee Farmer.*

South Berwick, March 29, 1838.

Mr. S. W. Cole:—Your letter of the 22d inst. requesting information in relation to the use of lime as a manure, has been received. My professional engagements have engrossed all my time till the present moment. I have no very particular knowledge on the subject, but will with pleasure state to you in what way I have successfully used lime as a manure, and how I have known it used by my neighbors.

I have used on my farm from ten to thirty casks of lime every year for the last twenty years; and have found it beneficial. Although a portion of my farm and buildings are on high ground, still between that and an adjoining swell of land there is a muck swamp, which formerly must have been a deep pond, and has been gradually filled up with vegetable matter, till the surface has become level with the adjoining land. This swamp is on higher ground than my barn-yard, and about twenty rods therefrom. The muck is inexhaustible, and is very easily hauled to the barn-yard. Immediately after haying, when the ground is very dry, I cart out about sixty or seventy loads of this muck, which is very sour when taken from the swamp; and I endeavor to manage it in such a way, as will correct its acidity, and make it food for plants. I have yards for my stock all around my barn. On the eastern side and southern end are yards for sheep, and on the western side and northern end are yards for neat cattle, surrounded partly by a high wall and sheds, under which there is a well of never-failing water. When the muck is taken from the swamp, about forty loads of it are dropped in the sheep-yards. Here the muck is spread and the sheep lie on it during the ensuing winter. The next spring immediately after planting, this muck, together with the sheep manure as well that in their yards, as that in the sheep-houses, is hauled round to the yards used by the neat stock on the farm. Here it is spread over the yards and intermixed with unslacked lime. The cattle tread over and lie on it during the summer, when in the yards. These yards are ploughed and harrowed, and more lime applied several times during the summer. The manure made in the barn during the winter is thrown into these yards, and the cattle during the whole foddering season, when not in the barn, lie there. As the yard is well supplied with water raised by a pump, no portion of the stock, except the working oxen, go out of the yard from fall till the next spring, when they go to pasture. The muck, lime, litter, manure and urine from the stock being well intermixed form a valuable compost, which in the spring is all applied to ground newly broken up, except that portion which is applied to root culture, other than potatoes.

My buildings are situated on the side of a high swell of land inclining to the west. The stable is connected with the house by a large shed, and on the further side of the stable is a hogs' yard, in which the manure from the horse stable is thrown. On the backside of the shed is a drain made of pine plank, free from sap, ten inches wide and four inches deep, covered with plank and dirt in those places where an open drain would be unsightly or inconvenient. This drain has been in use twenty years, has been renewed but once, and is now in good repair. The ground inclining, favors this arrangement. By means of this drain all the soap-suds from the kitchen, water from the sink, &c. must pass through the necessary vault, by which it is kept clean, to the hog-yard. A portion of the hogs on the farm are kept in this yard, and a dry and warm apartment is provided for them under a part of the stable. As soon as the yard is cleared of the manure in the spring, we begin again to fill it with muck taken from the swamp the year before, putting in at first five or six loads, and one or two casks of lime, and so on, muck and lime every few weeks during the summer. The manure of one horse in the summer and generally of two in the winter is thrown into this yard, and is often spread over the yard. During the warm season more lime is used in the yard, and scattered in the drain, whence it is washed into the yard, and thereby every unpleasant smell is prevented. All the leaves and dry litter which can be procured are placed in the apartment under cover for the hogs to lie on; and all the green weeds and wet litter which can be obtained are thrown into the hog-yard. The muck being formed of vegetable matter which has been decomposed without fermentation, is very bulky in proportion to its value as a manure—but is of some value in itself, and serves as a sponge to take up and preserve the juices and gases of the putrescent manure, which might otherwise be lost. Turf from a good soil, if it could be obtained without injury to the farm, could be used in the same way to equal advantage. By means of the muck, lime, horse-dung, litter, leaves, weeds, soap-suds, wash from the sink, necessary, &c. we make in this yard about fifty loads of the very best manure. Formerly in the spring we were accustomed to shovel this compost out of the yard, and suffer it to lie in a heap a few weeks till wanted to be spread on the corn ground. While it thus laid in a heap, it would become very much heated by fermentation, so that it one year killed a large elm-tree, about which it was thrown. For several years last past we have not thrown it from the yard till it has been shovelled into the cart to be conveyed to the ground where it is to be used. I have not observed but what the compost is equally efficient, when used without the fermentation produced by throwing it out of the yard. We generally keep a cask of unslaked lime in the cellar under the house, and another in the cellar under the barn, and scatter unslaked lime on that which is partially air-slaked, on the bottom of the cellars and in the pens from which the vegetables are removed. This lime is occasionally swept up, and carried to the manure-yard, and fresh lime again applied. In this connexion permit me to recommend the yearly use of whitewash in dwelling houses and cellars. With great gratitude I can say, that I have one of the largest, and most healthy families in the county, and I have no doubt but the liberal use of lime about my dwelling houses and appurtenances has contributed more than any other cause to preserve their health. I cannot accurately state the value of lime on the farm when used in this way, but am confident that it is much cheaper than to purchase manure at the usual price.

Until within a few years very little lime has been employed by my neighbors as manure, and the method in which they apply it, is that which is best adapted to general use, and is as follows:

Select a spot of ground near the place where the lime is to be applied to the soil by the side of the highway or in the pasture, where turf or rich vegetable mould can be obtained without injury to the farm. Spread a cask of unslaked lime on such a spot, then cover it with turf or vegetable mould, and so on alternate layers of turf and lime till the heap is raised three or four feet, or until the turf or good vegetable mould within reach has been used up. Then select the next best spot for the same operation, and so on till the lime is used up. This is suffered to lie in a heap till the next spring, when the heap is cut down perpendicularly, shovelled into a cart, hauled on to the ground where it is to be applied, dropped in very small heaps, and spread *suantly* (a Yankee word) over the ground which has before been ploughed and harrowed. The precise quantity which good economy would require should be applied to the land has not been ascertained, but I can safely say that from ten to fifteen casks per acre, at from one dollar to one dollar twenty-five cents per cask, prepared and applied as above-stated, would on scarcely any land be an injudicious appropriation of money. The use of lime in this vicinity has been extended yearly, as its good effects have been ascertained. It is believed that lime renders putrescent manure more efficient, when both are applied to the same land.

I have thus hastily answered your inquiries. If you think these remarks of no value, throw them aside, but if you think they will assist any one in the management of his farm you will make such use of them as you think proper.

Yours, &c.

WILLIAM A. HAYES.

P. S. I would remark, that very little wheat is raised in the lower part of the county of York. It is generally destroyed by rust. In the few instances in which I have raised a good crop, the wheat has been sown on very high land. The publication of this fact may induce others to observe whether wheat is generally more likely to escape rust on high ground.

W. A. H.

The two following communications were among those elicited by the queries on marling, stated in the 8th number (page 510) of last volume. The shape in which these are presented, is not that of special and particular answers to the queries, and, in addition, the limited range taken by each correspondent, (and permitted by his limited though valuable experience of results,) forbids the change of form required by the plan of digested information proposed in connexion with the queries; and therefore they cannot be advantageously used in aid of that plan. Nevertheless, the facts furnished are interesting and instructive, and as independent communications, the pieces are of a value of which we would be unwilling to deprive the readers of this journal.

Should any other correspondents than those to whom we are already indebted, attend to our former request on this head, we beg to remind them that unless they give special answers to the queries, (or to such as their experience permits, passing over the others,) their communications cannot be used as part of that plan of furnishing information on this important subject. But any other form of communication, however limited in range, or different in plan, and more agreeable to the writers, will be gladly received and published, as these are, as independent articles.—ED. FAR. REG.

LIMING AND MARLING IN MATHEWS COUNTY.

To the Editor of the Farmers' Register.

Mathews, Virginia, December, 1837.

Your circular letter of last month was received by mail, but it has not been convenient to make a reply until now. You request that the answers may be made in the order of the queries. As the use of marl has been very limited in extent and recent in this county, it may be more desirable to state what little information I have been able to obtain, from experience or observation, in an embodied shape.

I infer from the object of your undertaking, you wish to ascertain the effects of the carbonate of lime, in whatever mode it may be applied to the soil—whether in the form of shell lime, stone lime, or marl. I will therefore proceed to state my experience in the use of lime and marl.

I was, so far as my information extends, the first person who commenced the systematic application of lime to the soil in this county. Some had applied lime carelessly, without knowing its mode of application or its effects, and the consequence invariably was, a too heavy dressing, and the consequent injury sustained therefrom. It had been applied in small quantities from shell kilns or old mortar, and put on the land in the same manner rich earth or dunghill manure would have been applied. Hence, invariably, the spots where the lime had been thus applied, were rendered for some years unproductive, if not absolutely steril. Hence followed the condemnation of lime as a manure. When I commenced the use of it in 1833, I was told by many I should utterly ruin the land wherever I put lime. Marl has not been used by me until the present year. There is no marl in this county, which is accessible for agricultural purposes, except a small part of the county bordering on the Piankatank river. Those who use marl, are consequently under the necessity of transporting it by water from some of the river marl banks. I have this year brought from York river in a vessel between 3,000 and 4,000 bushels of marl, at an expense of 6 cents per bushel when on my landing, which I and two or three of my neighbors contracted with a gentleman on York river to deliver on board vessels at 2 cents per bushel. The freight cost $3\frac{1}{2}$ cents, and the expense of landing half a cent; which will make six cents per bushel. The expense of carting and spreading you have estimated, I think, at about half a cent per bushel. It costs me more than double that sum, as I am careful to have it measured in bushel boxes at measured distances, and spread with great care, so that I do not imagine the expense of applying would fall much short of two cents per bushel. Thus my marl, when put on the soil, stands me near eight cents per bushel. I put on from 100 to 150 bushels per acre. It contains by analysis 67 per cent. of carbonate of lime. One hundred bushels of marl would therefore be equal to sixty-seven of shell lime and 150 bushels to 100 of lime. I cannot state the effects of marl on the soil, as it has not had an opportunity of exhibiting its powers. One of my neighbors, year before last, (1835,) had a load brought from some of the river banks, and applied it to a wheat fallow with good effect. Certainly, his wheat was better than his neighbors', although it was a most unfortunate year to all wheat-growers. As we have so recently begun the use of marl, I cannot say any thing farther of its effects, but may do so at a future time, when they shall be perceived. I suppose there have been about 15,000 or 20,000 bushels of marl brought to this county by water, at an expense according with the foregoing estimate. There have been about 400 acres marled or limed in this county.

Having related all I know of the use of marl in this county, I will proceed to detail my experience in the use of shell lime. I have applied it in various quantities, from 25 to 100 bushels, and from observation, I think on land of common quality, containing some vegetable matter, that 70 bushels is about the proper quantity, although I have perceived as good effects from half the quantity.

My first application of shell lime, was on a fallowed lot of about 10 acres. This lot was very poor. It had been completely exhausted by a wretched cultivation without ditches. It would not have produced a barrel of corn to the acre. To a moiety of this lot, I applied lime at the rate of 100 bushels per acre on the ploughed surface without any other manure, harrowed and sowed rye over the whole lot. As far as the lime extended, the rye was killed as fast as it vegetated. The quantity was too great for the poverty of the land, and for a top-dressing. I saw my error; but my neighbors who had predicted a failure, smiled and said, "I told you so." The next spring I ploughed the land as far as the lime had killed the rye, and sowed oats. It produced a good crop. The rye was scanty. The next year I ploughed the same lot and planted corn. As far as limed, it produced by estimate three barrels of corn, the unlimed moiety not more than a barrel to the acre. After corn, the limed portion was sown in wheat. A little farm-pen manure was scattered lightly as a top-dressing on part of it, the remainder had none. Clover was sown on the wheat in the spring and harrowed in. The wheat was tolerable; about 8 bushels per acre. The clover which followed took well, and produced a pretty good crop. A part of it was cut for food. My neighbors were a little astonished, nay, they were convinced, and from that time has lime been looked upon favorably, and some exertions made to obtain it for manure. This lot laid two years in clover not grazed, was fallowed this fall; the unlimed moiety was marled on the surface (150 bushels per acre,) and manured with stable and farm-pen manure, and the whole lot sown in wheat. It is up, and now looks well. The portion marled did not destroy the wheat as the lime did the rye in the first instance, although the proportion of carbonate of lime was about the same in both cases. It is true the marl had manure with it, which no doubt prevented any injury from that mode of applying it. The lime had no manure to prevent injury from its causticity.

On another lot containing about 15 acres, which had been also reduced to as low a degree as that just described, I applied lime in the following manner. This lot had been permitted to lie two years without cultivation or grazing, and a heavy coat of coarse water-grass had grown up on it. It had been subjected to water, and was much water-sobbed, and very close. It is what is called a 'crawfish soil.' I had the whole lot ploughed up in the latter part of the summer, when the grass on it was yet green, and after being ploughed, I put on about one-fourth of the lot lime at the rate of 70 bushels, on another fourth at the rate of 35 bushels, and on the remainder no lime. The whole lot was planted in corn. As far as the lime went, there was no visible difference in the corn. The land containing 70 bushels produced no better than that which had only 35 bushels of lime. But up to the line where the lime ceased, the difference could be seen in the corn. That limed was estimated to produce three barrels, that not limed one barrel and a half of corn. Let us now see how the cost would stand. I purchased this lime from persons whom I employed to collect shells, burn them into lime, and deliver it at my landing at 10 cents per bushel; the cost therefore per acre would be as follows:

70 bushels lime at 10 cts. per bushel,	\$7,00
Carting and spreading, say 2 cts.,	1,40
Whole expense per acre,	\$8,40
Difference of product between the limed and unlimed:	
$1\frac{1}{2}$ barrels corn at \$4,50,	\$6,75
Balance of cost for the first year,	\$1,65

The next year the same lot was put in oats—the limed was doubly as good as the unlimed, and more than paid the balance due from the expense of liming. If the calculation be made at 35 bushels of lime per acre, a profit would accrue the first year as follows:

35 bushels lime at 10 cts.,	\$3,50
Carting and spreading, 2 cts.,	70
Expense per acre,	\$4,20
Difference of product between the limed and unlimed:	
$1\frac{1}{2}$ barrels corn at \$4.50 per barrel,	\$6,75
Profit per acre,	\$2,55

From this statement, the conclusion may be drawn, that the smaller quantity is as beneficial to the first crop as a greater; but it would require a speedier repetition of the lime, and I do not doubt the larger dressing will effect a greater ultimate improvement of the soil.

My observation of the effects of carbonate of lime, has in no instance discovered any thing contradictory of the positions laid down in your 'Essay on Calcareous Manures;' on the contrary, so far as they have extended, have been confirmatory. It has confirmed the facts: 1st, That where lime is applied sorrel will disappear. My land, where lime was put, had been very subject to the growth of sorrel. It was a cold, compact, sour soil, but becomes more open, puts up a different growth of grass; and I noticed on a lot partly limed and partly not, that the cows, when permitted to graze it, would invariably go to that part which had been limed; thus showing that a sweeter and more nutritious grass grew on it. 2d, That lime renders land fit for wheat which had not been before adapted to that grain. I have cultivated wheat with success upon land which had never been considered adapted to wheat, and had never produced that grain until lime was applied. 3d, That it causes clover to grow luxuriantly on land that would not previously produce it. Here I would remark, that I have been strongly impressed with the conviction, that your views of the action of gypsum on land after liming, are correct. I never could believe the old opinion, that the sea air operated to prevent the action of this powerful manure. Your view is more reasonable and philosophical. I had used gypsum on some of the same land now limed, before it had been limed, without perceiving the least benefit. It is my intention next spring to try it again on the same land. The results I may perhaps communicate, as I look upon it as a matter of great importance to all who design to lime or marl their lands.

WM. SHULTICE.

MARLING IN QUEEN ANNE COUNTY, MD.

To the Editor of the Farmers' Register.

Wye, Queen Anne County, Md.,
10th December, 1837.

I observe your queries in the last number of the Register, and wish I could answer them, or some of them, with accuracy to satisfy myself. I commenced the application of marl in 1824, with but little knowledge of its action, and have kept no memoranda. About the same time, I began the use of marsh mud, and found its immediate effects so much more productive, that the marl was neglected. In the year 1833, your book on Calcareous Manures was recommended to me by the late Col. Edward Floyd of Talbot. Your views on the subject have induced me to turn my attention principally to marl, for improvement of my lands. From two fields of about 45 acres each, marled for the most part since that time, and an intervening crop of clover, I gathered this year six hundred barrels of corn, and it is not in my recollection that they ever before produced more than four hundred; a small quantity of putrescent manure being carried out as usual. My marl is blue, mixed with sand, and our geologist, Dr. Ducatel, states it at 45 and 50 parts of shell. I applied 500 bushels to the acre.

WM. CARMICHAEL.

FARM REPORTS:

III.—*Netherby, Cumberland, (England.)*

MANAGEMENT OF THE HOME FARM.

The management of the Park of Netherby, the extent of which is upwards of twelve hundred and ninety statute acres, (independent of the woods surrounding and interspersed through the grounds,) comprehends the practical detail of a large grass and arable farm, managed on principles suited to the climate and local situation of the country, and occupied by the proprietor, not only with a view to the permanent improvement of the lands, but also to securing the largest return possible from them.

The detail is conducted by an active overseer or bailiff from one of the best-managed agricultural districts of Scotland.

The establishment consists of four regular ploughmen, each having the charge of a pair of horses; a steady elderly person, who has the charge of the granaries, and who superintends the field operations of hand-hoeing, reaping, &c.; and a park-keeper, who acts in the double capacity of superintendent of the whole grazing stock of cattle and sheep, and as butcher to the family. There is, besides, a person whose sole business it is to attend to the open and close draining of the lands about to be described, and whose services are of much consequence towards their good management. All these under servants have been very carefully selected. The female part of the establishment consists of a dairy-maid and an assistant in the cow-house. The establishment is so arranged that all hands are fully employed. All extra labor required at hay and corn harvest, and in hand-hoeing the various crops, &c. is very readily commanded from the adjoining market town of Longtown. Every account and payment incident to this establishment is kept by the overseer, and is regularly audited and settled by the agent once a month; and a copy of the monthly account is duly put into the proprietor's hands, who is thus enabled to have the real situation of his farming matters constantly under his eye.

Extra work, such as mowing, draining &c. is let by contract to laborers.

Description.—The management about to be described extends, as already mentioned, over about twelve hundred and ninety acres. The soils are of various descriptions, and consist of the following general divisions:

1st. On the banks of the river Esk, which cuts the grounds into two portions, the soil is a loamy clay on a porous bottom, and very various in point of quality, as is generally the case with all lands whose formation is the deposite or washings down of lands situated at a higher level. These lands are under permanent pasture.

2d. A mossy soil of no great extent, but of considerable depth, incumbent on clay, now irrigated meadow land.

3d. Gravelly soil, on an open bottom of gravel, technically called a rusty gravel, held in pasture or alternate husbandry; and,

4th. A clay soil of various qualities on a close till or stubborn clay subsoil, unsuited to constant pasturage, and therefore kept in alternate husbandry.

The lands consist of about 480 acres loamy clay, $28\frac{1}{2}$ acres meadow, 320 acres gravel, and 462 acres clay soils.

The aspect is generally flat, but with a gentle undulating surface, and with a moderate inclination from the river which runs through the lands in a direction from N. E. to S. W. The whole lands lie compact and in a ring fence, and form together a very beautiful park, equal to any in the north of England, not only in point of appearance, but in real value, while these lands do not lie at more than from 70 to 120 feet above the level of the Solway Frith. The management of each kind of soil being different, requires a distinct and particular description, as will be found in the following account.

The farm buildings at Crofthead stand very nearly in the centre of the grounds, which has been found of great advantage in their management.

Longtown.—A considerable market town, containing from 1800 to 2000 souls, through which the great road from Edinburgh to London by Carlisle passes, is situated at the S. W. angle of these lands.

No manure can be procured here except what is produced on the farm, in the farm-yards at Crofthead, and what is purchased at Longtown. Of the last—as the farmers in the neighborhood procure all they can—no great quantity of manure can be obtained. There is abundance of lime, however, to be got within four miles, at a price averaging about 3*s.* per single cart-load at the lime-kilns, or 4*d.* per imperial bushel. No chalk, clay, or shell marl is found in the neighborhood, and the chief dependence is on dung and compost made on the lands, and lime as already stated.

Turnips are indeed consumed on the lands, where the soil is dry, by sheep.

A trial is just now in progress of using bone dust, as a manure for the production of turnips; and if it succeeds, as is expected, this assistant will be much used here in future.

Draining.—The first operation of management has been *in every case* to ensure a complete under-drainage, to relieve the lands from the springs by which they were surcharged, as well as attending closely to open draining. The improvement of close draining has been most effectually done by tiles manufactured on the estate, at a distance of about three miles, and in the same manner as is practised in Staffordshire and Warwickshire. Many hundred roods of drains have been executed in this way, and with complete success. The open draining has also been a point of paramount consideration. The ditches, or main drains, have always invariably been cut out to the proper level, so as readily and freely to discharge the water delivered into them. The sides are carefully sloped back by the spade, so as to discharge the water from the ridges; and the earth so cut away, as well as all high head-ridges have been in every case most carefully mixed up with lime, repeatedly turned over at proper intervals, and, lastly, applied as a rich compost in top-dressing the adjoining lands, after being depastured for the first two or three years. It is very surprising that sloping in the sides of main drains, and open ditches, which is a means of providing an ample supply of rich manure in thousands of cases, is almost invariably neglected by the practical farmer; and that he should equally neglect to remove the high head-ridges existing in almost every field (occasioned by the repeated use of the plough), which would be the means of enriching the adjoining lands at an inconsiderable expense. This, with ditch and road scrapings, and every possible means of increasing the quantity of putrescent manure, have been closely and successfully attended to here, and with great success; and as the application of compost so collected has been almost in all cases to pasture lands, the effect has been excellent; while the grounds, when broken up for white crops, after being so manured, have —even on very inferior soils—yielded full and fair crops. Indeed the system pursued for a number of years, of turning every particle of soil not required for the production of useful crops, into compost to be applied as a top-dressing to the grass lands has been found very beneficial.

Management of Pasture Lands.—The climate here, in common with the whole west coast of Britain, is rather wet; and considerable quantities of rain fall in Cumberland, in consequence of its proximity to the Atlantic. Dry soils therefore are of the greatest value here, and grass husbandry on many accounts is the most proper and natural for the district.

When lands are well and judiciously laid down to permanent pasture, the expense of their management is at once reduced. The local situation of this part of Cumberland, bordering on Scotland, renders it in a great measure a grazing or cattle-dealing country, and pasture land, of a good quality, is constantly in request, and yields full and fair rents, when let from year to year; or, when farmed in a run of seasons, it produces, either by cattle or sheep, a fair return to the grazier. The greatest part of the cattle and sheep sold in the great Scotch markets, in Galloway, and the north of Ireland, pass through this country to Carlisle, the great point where they change hands.

Old Grass Lands.—Around the house of Netherby a very considerable extent of old grass land exists. This has been completely under-drained; and as it was disposed to produce moss—so as to render the pasturage late in coming to maturity—a very heavy dose of *hot lime* was applied about ten years ago to the whole, with remarkably good effect; for after the first year's application, the moss was eradicated, and the pasture is now unrivalled in the country. The soil alluded to is generally good clay loam on an open bottom.

New Grass Lands.—Whether on light or heavy soils, it has been the constant custom here, in the first place, to lay the lands completely dry by under-draining; then to clean and pulverise the lands completely by summer fallow or green crops; to apply all the putrescent manure that could possibly be produced or purchased at a fair price. On light soils, turnips are consumed, by sheep folded on the grounds; and on clay soils, the turnips, if any are produced, have been regularly consumed in the farm-yards, and the manure so produced has been applied to the ensuing white crop. In all cases, supposing the lands (of whatever description of soil they may consist) to be thoroughly cleaned, the course here has been to sow out to permanent pasture with the *first* white crop, and with the following variety of pasture seeds, *viz.*

If Clay Lands,

Timothy Grass - - -	Pleum pratense.
Pacey's Ryegrass - -	Solium perenne.
Red Clover - - - -	Trifolium pratense.
White Clover - - -	Trifolium repens.

If Light Dry Soils,

Pacey's Ryegrass - -	Solium perenne.
Red Clover - - - -	Trifolium pratense.
White Clover - - -	Trifolium repens.
Cocksfoot - - - - -	Dactylis glomerata.
Rib Grass - - - -	Plantago lanceolata.

Hay *is never* taken from lands intended to remain in permanent pasture. These lands, whether heavy or light soils, are constantly depastured with sheep for the first season. If clay lands, the grass is depastured from 1st May to 11th November, and if light soil, from 1st May to 1st March yearly; and no stock of any kind is admitted on either description of soil between the terms mentioned. The second year any ordinary description of stock is admitted. In the course of years it has been found necessary to break up some part of these lands, and to lay them down anew to permanent pasture: the following varieties of pasture seed are now sown and approved of here.

Clay Lands,

Timothy Grass - - -	Pleum pratense.
Cocksfoot - - - - -	Dactylis glomerata.
Meadow Fescue - - -	Festuca pratensis.
Dog's-tail - - - - -	Cynosurus cristatus.
Meadow Cat's-tail - -	Pleum pratense.
Pacey's Perl. Ryegrass	Solium perenne.
Red Clover - - - -	Trifolium pratense
White Clover - - - -	Trifolium repens.

Light Lands,

Timothy Grass - - -	Pleum pratense.
Pacey's Perl. Ryegrass	Solium perenne.
Cocksfoot - - - - -	Dactylis glomerata.
Rib grass - - - - -	Plantago lanceolata.
Dog's-tail - - - - -	Cynosurus cristatus.
Mixed Fescues - - -	Festuca duriuscula, Festuca, pratensis, &c.
Mixed Poas - - - -	Poa pratensis, Poa cerulea, &c.
Red Clover - - - -	Trifolium pratense.
White Clover - - - -	Trifolium repens.

The inferior description of clay lands in particular have been much improved by opening the furrow every autumn, about the month of November, by means of the furrow draining plough—an implement of simple construction, but one that cannot be too well known by the agriculturist. Its object is to cut a furrow slice out of the already existing furrow, 6 or 7 inches deeper, while its mould board, formed of wood, throws this slice 8 or 9 inches clear out on the right-hand side of the plough—thus forming a complete (we may say almost invisible) drain—which lays the land dry, and which discharges all superfluous water through the ensuing winter, while the furrow slice so removed is an addition to the compost heap. This simple implement has been of the greatest use here, and is strongly recommended to all farmers of wet clay lands.

Double Digging or Trenching.—Last year, during the distress of the hand-loom weavers, a large extent of ground of a very stiff clayey nature was trenched by those out of employment, in order to employ them. The deepness trenched was eighteen inches, and the inequalities of the surface were regularly reduced and attended to, and the grounds planted with potato and mangel wurzel, properly drilled and manured. Next year wheat will be sown, and the ground laid down again to permanent pasture.

Irrigated Meadows.—Here there are 18½ acres of water meadow on the ridge or bed system, and about 10½ on what is termed catch-work. It happens unfortunately that the water collected in a brook, descending through the lands to the Esk, is hardly sufficient, except in floods, for the purpose of complete irrigation. But the heavy crops produced even under imperfect watering, leave no doubt, however, of the utility of this branch of agriculture.

There are no other meadows here, and indeed the want of meadow ground is seriously felt over this district. In the general management of the pastures, care is taken to eradiate docks, thistles, &c., from the surface; and moles are destroyed whenever their workings appear.

ROTATION OF CROPS.

The plough rotation followed on these lands has been as follows—on

Gravelly soils.—1. *Turnips.*—Generally Swedes or Aberdeen yellows, consumed on the ground by sheep.
2. *Barley.*—Sown about the middle of April with seeds for pasture: the lands laid generally quite *flat* in the surface.
3. Young grass seeds depastured by sheep; generally ewes and lambs, from 1st May to 1st March.
4. Pasture.
5. Ditto.—Top-dressed this season with compost.
6. Pasture.
7. Pasture.
8. Pasture.
9. Oats out of ley.

Clay lands of the best description.—1. *Summer fallow*, or, if the season is suitable, globe turnips. In either case, the land thoroughly cleaned and manured. Turnips pulled and consumed in the yards by cattle.
2. *Wheat*, sown in autumn; and grass seeds for pasture sown in the succeeding spring: no stock of any kind allowed to depasture these seeds in the ensuing winter.
3. *Young pasture seeds*, depastured by sheep from 1st May to 11th November; but unless the ensuing winter should happen to be particularly dry, no stock admitted after that period.
4. Pasture for the same period.
5. Ditto, ditto.—Top-dressed with lime or compost.
6. Ditto, ditto.
7. Ditto, ditto.

If the lands now begin to show moss, so as to hurt the pastures, and render the grass later in coming to a full bite, they are generally ploughed for oats in the eighth year, about the middle of winter, so as to derive advantage from atmospherical influence, and are ploughed with a strong furrow.

Clays of the second-rate description.—1. *Bare fallow.*—Thoroughly cleaned, limed, and manured; the greatest pains being taken in all cases of clay land in the ploughing, so as to give the ridges a proper shape, to discharge all surface-water from the centre to the furrow.
2. *Wheat*, of the red kind, or oats, sown out with seeds for pasture.
3. *Seeds*, depastured by sheep from 1st May to 11th November.
4. Depastured by any kind of stock from ditto to ditto.
5. Depastured by any kind of stock from 1st May to 11th November. Top-dressed with lime or compost.
6. Ditto, ditto.
7. Ditto, ditto.
8. Oats out of ley.

These various courses of cropping have been found to suit the lands extremely well. The application of lime or compost to the third year's pasture, is a point never overlooked; for it is found to renovate the pasture grasses, and the grounds, after an interval of two or three years, break up in capital condition for oats.

Wheat.—The wheat sown on the best descriptions of soil is invariably the white kind. That most in request for seed is understood to be what is called, in East Lothian, "Hunter's wheat." Wheat, after summer fallow, has always been found of the best quality and greatest weight to the acre; on inferior clays, red wheat is often sown. This variety is certainly well suited to such soils, and often fair average crops are obtained; but it is thicker in the husk, and therefore not so much in request with the corn-factors. The price in the market is generally one shilling per Carlisle bushel under the price of white wheat.*

*A Carlisle bushel is equal to 3 A imperial measure.

Sowing.—The quantity of seed wheat to a statute acre sown broad cast, is from two and a half to three imperial bushels. The usual return, in favorable seasons, may be about from thirty-four to thirty-eight imperial bushels per acre.

Period of sowing.—On summer fallows, wheat is sown about the second week of September; and if wheat is tried after turnips, fed off on the lands by sheep, which is sometimes the case on lighter soils, the sowing being performed during the winter months in proportion as the turnips are consumed.

Tares or vetches—Are seldom or never sown in this district. They answer, however, admirably in this district on fresh soils: they have invariably yielded a very large return of green food for soiling, and have been sown on purpose to be ready to be cut as green food, between the first and second crops of clover. Tares are never made into hay in this district; and indeed from the great quantity of succulent matter they produce, in a variable climate, the process of making them into hay would be attended with much risk and probably little advantage. They are very useful when consumed in summer, in soiling by cattle or horses, and thereby adding greatly to the dunghill—a point of paramount importance, but in no other light is their culture recommended.

Rape.—Rape succeeds here very well on lands in fair condition. An experiment on rather a large scale, was tried about eight years ago, of sowing in the month of July, no less a quantity than 120 acres of land of the first-rate quality—of loam intended for permanent pasture—with rape alone. The ground was previously thoroughly cleaned and limed, the rape and grass seeds sown, and the rape, immediately on arriving at maturity, eat off by sheep. The effect has answered, and the lands in question are the best pasture in the country at this moment.

Turnips.—The turnips sown here are the globe, the Aberdeen yellow, and the Swedish; all these varieties, when the seed is good and fresh, and the proper culture followed, have invariably succeeded here. The globe is consumed first, then the Aberdeen yellow, and lastly the Swedes. A number of other turnip seeds have been tried, such as the tankard, the green round, &c.; but from experience, the three kinds first named are decidedly preferred.

Drill husbandry.—Turnips are always drilled here, and without a single case of failure. The turnip husbandry of East Lothian and Berwickshire is followed from first to last. The crops produced are generally heavy, sound, and good, even on the stiffest description of clays. These crops are either consumed in the farm-yards by cattle, or on the ground by sheep. In eating off turnips by sheep, the practice here has always been at first to confine the flock on an extent calculated to support them fully for one week, and to give them a fresh break once a week afterwards, allowing the flock the range over the first portions of ground allotted to them. Hay, in sheep-haicks or cribs, is given along with turnips; Swedes are undoubtedly a most valuable crop to the farmer, and are the favorite food of all sorts of cattle and sheep. It is the custom in this establishment also to give the working horses, in the winter and spring months, a considerable proportion of Swedes daily; and the effect is to make the animals eat their oats with more avidity, and to render them more fresh, and their coats more glossy. No other crops (potatoes, beans, and mangel wurzel, excepted,) are drilled here. On the light soils, however, there is not the least doubt that all the white crops may be drilled and hand-hoed with the greatest advantage; and it is in contemplation to resort to this mode of culture in future, as the most garden-like management, and as yielding a heavier and better description of grain, while at the same time all annual and other weeds are destroyed. Swedish turnips are sown in the latter end of April or beginning of May; globe and Aberdeen yellows during the first and second weeks of June. It is proper to mention, that the sheep generally fed off by turnips, are the best description of Cheviot wedders from Sutherland, Roxburgh, and Dumfrieshire. Ewes and lambs on turnip, are seldom or ever attempted here. It would be reckoned very slovenly management to allow turnips to sprout in spring; they are always consumed when perfectly sound in the bulb, whether in the yards or in the fields.

Barley.—Barley succeeds turnips which were consumed on the ground by sheep: of course these crops can only follow with advantage in rotation on turnip soils. If the turnips have been properly managed, as already described by the eating them on the ground, the lightest soils will be compactly beat together by the treading of the flock. One furrow on such soils is considered in general sufficient, and the proper time of sowing is from 1st April to 20th May. It is here proper to state, that barley after turnip should be sown *hot furrow*, that is to say, the sower should immediately follow the plough, and the harrow the sower; and probably, if the weather appears to set in droughty, the grass seeds and roller should close the scene behind the harrows. When the process of barley-sowing is conducted in this way, a failure of crops has never taken place here. Pure barley alone is sown; and the old variety, called rough beer or big, seems, with much propriety, to be quite out of fashion in the district. These grounds seldom fail to produce barley of an excellent malting quality; indeed, the vale of the Esk is celebrated for the good quality of its barley crops.

Grass.—Grass never fails to succeed here after barley. If it is intended to cut the grass crop green for soiling, ryegrass, with a large proportion of red clover, and a small proportion of white, are sown. The soils here, from the management described, are generally fresh; and not one single case is remembered where the clover crops have failed altogether on any of these soils.

Ryegrass—As a hay grass, is a very valuable variety; but when land is intended for permanent pasture, or for lying a number of years, ryegrass does not appear to be so well adapted as many other varieties for grazing purposes, and hitherto too much seed of this kind has been sown here on permanent pasture lands.

Fiorin Grass has never been cultivated here. It is probable, however, that practical agriculturists may, in many cases, entertain unfounded prejudices against this grass. A small fiorin meadow, as a trial, is in the progress of being laid out at present.

Sainfoin is never sown in this district, and clover is seldom or never sown without a mixture of grass seeds along with it. One experiment, on good land, of sowing red clover only, succeeded admirably.

Potatoes, under good management by the drill system, never fail here, even on the clay soils. No great quantity, however, is ever grown on this farm, except for the use of the family.

Mangel Wurzel has been cultivated for two or three years. The growing of this esculent is, however, quite new in the district, and is therefore only cautiously attempted at first. The result, hitherto, is favorable, although the Swedish turnip is supposed to be a crop of equal value.

STOCK.

As feeding cattle for the butcher has always formed a principal point in the management of these lands, it is considered a matter of importance to select the breeds likely to arrive soonest at maturity. The pure short-horned breed, selected with care and expense from the stocks of the Messrs. Collins and other celebrated breeders, have long been used here, and on the best description of soils, with success. Various crosses have also been often tried between the short-horned and other breeds, and the result in general has been favorable for the first cross. The second cross produces here by no means so good an animal as the first. The cross between the short-horned and highland breeds produces a very good animal, with every tendency to feed, but of a nature almost as wild and untameable (and sometimes more so) as its highland progenitors. The cross between the short-horned and Ayrshire breeds produces a very good animal, generally well suited for dairy purposes. The cross between the short-horned and polled Galloway breed produces a very excellent animal, possessing, in a great measure, the feeding qualities and best points of the short-horn, and the hardiness and docility of the Galloway cattle. On good lands, this cross is here preferred to any other stock. The pure short-horned cattle are found, after many years' experience, to be rather too tender for the climate, and difficult and expensive to winter.

Galloway cattle are the general stock of the district. They possess many advantages, as they can at any time be brought to market. Their hardy and very healthy habits fit them well for the climate and soils of Cumberland; and although the first cross with the short-horn does produce a good beast, no good breeder would choose to continue his stock from these crosses. Thirty of the best West Highland heifers, and four-score aged Highland black-faced wedders for the family use, along with the Galloway cattle, form the permanent stock on these lands. But from their extent, it is impossible to winter as many cattle as the grounds can summer; and therefore in April and May yearly, a flying stock of cattle, chiefly Galloways and West Highland heifers, are purchased in the local markets on their journey southward, and fed off on these pastures; and it is the custom to have an annual public sale of this flying stock. They are sold in lots, and are generally bought by cattle dealers and butchers. The greatest number are resold again at the great fair of Broughhill in Westmoreland, on the 1st of October. Thus the pastures are completely eased at the proper season, and left rough for the wintering stock, and about this period all accounts are settled, the remaining stocks, crops, &c. valued, and the profits or loss on the whole concern annually struck.

Sheep.—Except the black-faced stock already mentioned, as kept for the consumption of the family, no other sheep are kept, for it has been found that cattle pay much better; pure Leicester and South Downs have been kept as breeding stocks, as well as Cheviot and half-bred sheep, but the result has been to abandon a breeding stock of sheep entirely.

Lambs.—The breeding of lambs for sale to the butcher, has never been followed here, but breeding for a stock has been. The ewes have in every case lambed in the open pastures, and little or no loss has ever ensued from the practice.

In extensive stocks, it is impossible to protect the ewes in the lambing season, from the fall of rain or snow. In very small stocks, sheds for sheep may answer a very good purpose, but it has never been found necessary to provide such protection here. Folding ewes in a confined place in the lambing season, is decidedly an improper mode, and is never practised in this country.

The sheep commonly grazed in the district are the Cheviot breed, but probably the most profitable is the half-bred or cross, between the pure Leicester, and the pure Cheviot; for these possess the stamina or hardy constitution of the Cheviot, with the docile and gentle nature and feeding qualities of the Leicester breed, while the wool is improved by the cross Sheep are seldom laid with tar and butter on these grounds, but otherwise every thing that can conduce to their health and comfort is attended to by a careful person who manages the stock.

Horses.—The farm horses in greatest repute in this district are the rough-legged Clydesdale or Lanarkshire breed. In this establishment, these and the Cleveland horses are generally used. The preference in the reporter's opinion is due to the Cleveland breed, for they are more quick in their movements, and consequently better adapted to light soils than the Clydesdale, which breed, however, is admirably adapted to heavy soils, and are remarkably quiet, and generally possess good constitutions.

Pigs.—This particular district produces great quantities of bacon and hams for the London and Liverpool markets, and the breed of pigs is in consequence a point much attended to. There are different breeds here, but the kind preferred in this establishment is what are provincially called the "prick ears," a well made, short-legged animal of its kind, of a yellowish-white color, averaging, when quite fat, sixteen or seventeen stone of fourteen pounds each. This variety seems of a remarkably sound constitution, and is generally fed off at from twelve to fifteen months old. In this district pigs are allowed a range of pasture, with food in their piggery at regular intervals, and they thrive remarkably when so managed. On this farm, however, they are only allowed the range of the straw-yards. They consume the refuse from the kitchen, aided by potatoes, &c. steamed for their use, and they have always yielded a very fair return.

Management.—Cleanliness, as well in making ready the food as in the piggery, is essentially necessary to promote the health of the animal, and fresh beds of clean straw are regularly given them. A steaming apparatus on the most approved principles for preparing the food of the horses, dairy cows and pigs, has always been used here, and ought to be used on every large farm, but attention should be paid not to give any food more than lukewarm to any stock.

IMPLEMENTS.

Ploughs.—Iron ploughs only are used. The first of the kind was manufactured by Wilkie, of Uddingstone, near Glasgow, but these implements are now regularly made on the best construction, by tradesmen in the neighborhood. They are uniformly drawn by two horses abreast only, and with such ploughs and horses, any kind of soil may be well cultivated. The furrow-cutting plough, described under the head of grass husbandry, may be made by any plough-wright, and is a most useful implement. The number of horses employed in drawing it, depends on the depth of the furrow, and the nature of the soil.

Carts.—Carts with iron axles and two shafts, as commonly used in Lanarkshire, drawn by a single horse, are decidedly the best, and no other kind is used here. In harvest and hay-making, a frame is mounted on the shelvings of such carts for bringing the crops from the fields.

Harrows.—Finlayson's patent harrow is greatly used here for cleaning lands. It is a very useful and excellent implement for such purposes. The common seed harrows are in use on this farm; some of these are made of iron.

Drill Machines.—A machine for sowing turnips by two drills at once is used here, and another machine mounted on a small wheel, and pushed by a man, for sowing grass and clover seeds, is also in use.

Threshing and cleaning the Grain.—At first for many years this was done by a threshing machine driven by horses—latterly, it is altogether done by hand labor and by the flail, and paid for by the bushel of cleaned grain. The expense is probably as cheap by the flail as by the machine, and employment is thus given to the poor, and every purpose required is answered by the present practice.*

MANURE.

No part of rural economy is less understood or attended to than the management of manure; and it would require a treatise on the subject to detail the systems pursued in the best farmed Scotch districts, which are always held as the guide for good management here. It may be shortly stated that all the urine from the stables, yards, cow-houses, piggeries, &c. is carefully conducted by under drains into the dung-pits. The dung collected is carted out during the winter for turnips, and laid up in convenient places for a speedy application to the lands, the instant the season suits for sowing. The middens, or dung-hills, in the fields, are hollowed out in the bottoms, so as to prevent the moisture from escaping, and are regularly covered with mould. The carts are never allowed to pass along the dung-heaps. The manure made in summer, when cattle get green food in the house, is always of better quality than winter-made dung, and is generally applied to the summer fallows. Short dung is unquestionably most suitable for turnips, as in that state it affords no interruption to the plough and drill. Long dung, that is to say, dung not fermented, may be applied to potatoes without any impropriety. The management of compost occupies considerable attention; frequent turnings, and probably twelve months are required to reduce the stubborn lumps of clay often used in the making compost, and turnips are in many cases raised by no other application.

GENERAL CHARACTER OF THE DISTRICT.

The estate, of which the lands here described form a part, consists of an extensive district, in which there is a very considerable quantity of good loamy clay and gravelly soils on the rivers, but by far the greatest portion is clay soil. Horses are regularly bred by almost every farmer, and the dairy husbandry (chiefly in the making of butter) is largely followed. Every person produces a certain number of young cattle as well as fat beasts for market, and large quantities of pork and bacon are produced, besides considerable quantities of wheat, barley, oats and turnips. In this district, where a mixed system of husbandry is followed, from the necessity of attending markets, and from having a considerable intercourse with strangers, the farmers are sharp clear-sighted people, alive and ready to adopt any successful experiment, *after it has succeeded under the proprietor's management.* On this estate, a local farmer society, confined to its bounds, but having three hundred members, has long existed, by whom prizes are yearly awarded to every branch of good management in agricultural matters, and to the various descriptions of stock. The yeomanry thus meet regularly once a year; they hear the management of their farms discussed openly and freely; good managers are praised and rewarded, and indolence and bad management would be ashamed to exhibit themselves. All the good stock of the country is annually shown, and the spirit of emulation is invariably attended with good consequences at the next meeting.

The country is purely agricultural. No man is above his profession, and almost all are possessed of means fully equal to managing their lands in the best style. The country is now enclosed and subdivided into suitably sized fields. Quick hedges of thorn, kept neatly dressed by the pruning knife, are the common fence of the country, and few countries can boast of better hedges than this.

Except along the sides of the great roads, hedge-row trees are not usually seen or planted, and the country where grain is chiefly produced, has been purposely and judiciously left open, to admit a free current of air and sun to the crops, a point of much consequence in bad seasons, and in a climate as damp as this is. This district lies low. It extends from the head of the Solway Frith, rising from the level of the sea, with a very

---

* The experience of every other district of the kingdom is contrary to this conclusion. The machine threshes much more cleanly, and it is equally beneficial to the consumer and the farmer, from the facility with which it enables the latter to meet all the changes and exigencies of the market.

gentle general rise for twelve miles, to an altitude of about five or six hundred feet. The district is not subject to any epidemical disease. The people are temperate in their habits, and often attain a great age: pulmonary consumption, however, frequently makes its appearance, particularly in the vales descending towards this open country; and numbers of the youth of both sexes are cut off by this fatal malady.

PLANTING.

The management of plantations is probably foreign to the common operations of the farmer, but the shelter which they afford, render them at all times, and especially in an open district, objects of great moment even to him. Hundreds of acres have been planted on this estate, and the general success has been cheering. Trenching by the spade has never been done here preparatory to planting timber, the scale on which planting has been conducted being far too large to be managed in this way, but the lands have in every case been laid dry by open drains, and in some cases (particularly in planting land covered with short ling) the ground has been ploughed before planting by a plough drawn by four horses. For the first three years, the young trees have not grown so luxuriantly as might be desired, but in the fourth year, and afterwards, they push out vigorously. In every case care has been taken to plant hardwood trees of oak and ash, &c., and at such spaces that they may ultimately become the standard trees; and larch and Scotch fir are, in the meantime, planted as nurses, to be removed according to the necessity of the case. Every variety of tree thrives well on this property, but more particularly on the loamy soils.

CAPITAL AND ACCOUNTS.

Without an adequate capital, good farming cannot be followed. This, however, though a point of first consequence, we fear is often too little considered by the young farmer, and probably by the proprietor in letting his lands. Before letting lands, the proprietor or his agent should, if possible, be thoroughly acquainted with the farmer's means and capital, as well as his general habits and disposition; and if this is insisted on, it will prevent, in many cases, tenants of inadequate capital and bad character from obtaining leases.

Few, or almost no farmers, keep *regular* accounts, and the consequence is they are often in the dark as to the true state of their affairs. A system sufficiently simple and concise might be easily contrived to answer all the ends in view; but, from prejudice or want of habit, it is to be feared the general run of farmers dispense with the keeping regular accounts.

Laborers.—Laborers are easily obtained here, either for piece-work or by the day. Their wages by the day are generally 1*s.* 4*d.* to 1*s.* 6*d.* in summer, and 1*s.* 2*d.* to 1*s.* 4*d.* in winter. These men are bred from infancy to all kinds of agricultural labor, and are generally expert in the use of the spade, scythe, &c. The real good farming laborer here cannot, with justice, be said to be in distress, for he always finds employment; and in this district the laborer has advantages unusual in some other parts of the country. For instance, his fuel costs only his own labor in cutting and preparing the peat; he, in every case, keeps a pig, and sometimes two; and the manure, ashes, &c. his pigs and cottage produce, are readily laid on by the farmers on their fallows for the cottager, who receives one crop of potatoes from his own manure. The great evil is early marriages: young men generally marry before they are twenty, and the females much sooner, and the alarming extent to which bastardy has increased in the country is a most serious evil. No laborers in these parishes possess any little property, such as a cottage and garden of their own. The poor-rates have not increased here for eleven years past, and the county rates are rather less now than at that period. The farm laborers are generally well behaved, cheerful, and obliging; and it is very rare indeed that any of that class ever appear to solicit aid from the parish vestries.

POOR-LAWS.

The lands described are situated in two parishes. The management of the poor-rates is conducted in each parish by a select vestry, under Mr. Sturges Bourne's Act, the rector of the parish acting as chairman. The poor, (chiefly the aged and infirm, and the hand-loom weavers of Longtown, and some small villages in the neighborhood,) have their various cases heard and relieved, and if ever there is an appeal from these vestries to the local magistracy, the case of the applicant is fairly and properly inquired into, and suitable relief afforded. Indeed, there is an evident wish among all parties to do what is fair and just to the poor. The presence of the clergyman in these vestries, however, has no doubt had a great influence in checking any thing improper on the part of the members of vestries.

Assistant Overseer.—Each parish has an assistant overseer, who, besides a regular salary, receives ten per cent. on all moneys he may recover from the fathers of illegitimate children. This is a point of much consequence, for, from the local situation of the district, divided from Scotland by an ideal line, the fathers of such children, from either side of the border, easily escape from the maintenance of their progeny if they are so disposed. These overseers are thoroughly acquainted with their profession, are respectable in their way, have a perfect knowledge of the paupers, and are exceedingly useful in keeping down the poor-rates and seeing the funds properly applied.

CHARACTER OF THE PEASANTRY.

As already remarked, the peasantry are generally civil and obliging in their dispositions, and grateful for the good treatment and kind words they may receive from their masters. It is a truth which constantly strikes the reporter's observation, that however illiterate they may be themselves, the peasants strain every nerve, and often deny themselves many little comforts, in order that their scanty funds may be saved to get their children decent education at the parish schools. It is no uncommon thing for laborers to continue in one master's employment many years, and on this farm of Netherby all the servants have been in their present service for a long period, although their engagements are only from week to week.

Parish schools.—In these two parishes, there are eight endowed schools, at which all the useful braches of common education are taught by schoolmasters appointed by the rector of the parishes: these schools deserve, and do receive every support from all classes of society here, and are indeed a blessing to the country. The many thriving and wealthy merchants and tradesmen of respectability, natives of this district, now settled in London and elsewhere, fully prove the good effects of educating the lower orders, and the example of the good character and the enterprise of the young who leave the district, acts as a spur to push on those left at home to emulation and good conduct.

Means of improving the condition of the peasantry.—Ploughmen cannot be employed by the piece,* but a great portion of agricultural labor may be so done. It has long been the practice on this farm to let every thing possible by the piece, as a matter of justice and propriety, both to the employer and his laborers. This is a most encouraging plan to the industrious peasant, who thus secures the fair return for his labor. Jobs are always let by estimate, but the competition, though fair, is never so very keen as to reduce the prices given too low.

Medical aid.—The family surgeon attends the whole permanent servants of the establishment in cases of bad health, and he receives a regular allowance for his services.

Gardens.—All the permanent servants have small gardens, well kept. These patches are a source of great comfort to the possessor, and a rational amusement at his leisure hours. A few of the ploughmen are allowed to keep a cow each, on paying a very moderate rent for the pasture through summer.

Separate dwellings.—The dwellings of the laborer ought undoubtedly to be separate from each other. This, however, unluckily, is not the case here, for all the permanent servants live under one roof in a large three-story building erected many years ago, near the farm-yard. These people are all respectable in their way, but huddled together as they are, it is not possible to prevent little quarrels and bickerings from breaking out occasionally, where people with families (although each has two separate rooms,) are so congregated. It is in contemplation to remedy this mistake, by erecting separate cottages for the servants.

Residence of the proprietors.—In this district one great proprietor owns the whole, whose residence is constant.

Marriage.—There can be no reason why the laborer should not marry, except that they are too ready to enter into that state when very young, and before they have saved a little money to begin the world with; though as yet, the excess of the agricultural population is not felt as a serious burden in this district, for the country is making rapid strides in improvement, and all good hands find at present ready employment.

Believing that details of real practice are of more use to the cause of rural improvement than theoretical opinions, unsupported by the test of experience, the reporter has confined his observations, as closely as possible, to giving an accurate account of the management of a gentleman's park and farm on a large scale; and he has only further to say, that the profits or returns have been always fair, and such as completely to warrant a communication of the systems pursued.

Glinger Bank, Longtown,

*But for that reason are paid at a higher rate of wages than the ordinary day-laborer.

For the Farmers' Register.

THE MORALS OF MANURING.

Bad health is a good excuse for most of the negligences of man; and it is with grief that I offer you this for not communicating with you more freely. Little now remains to me in life more dear than to give my young friends the benefit of my experience, and show them how to make themselves prosperous, abundant, and happy. Holding, as I do, that the moral power of every community depends upon the facility of man's obtaining subsistence, I assume as undeniable, that he who teaches how ten grains of corn and as many blades of grass can be grown where now but one can be shown, in that very proportion increases the moral power of society. In plain disrobed English, I hold that our duty to Mother Earth is the basis of moral law and moral duty; and disguise it as you may, the facts which sustain me are abroad and "trumpet-tongued." Neglect of this duty has created the necessity of legislating society to death, or into deep disease; but this is mere quackery. Loco-focoism is marking and banding its party, and in the fulness of time it will produce the madness of battle, and, like that of the cats of Kilkenny, nothing but the tails of the combatants will be left. Man is strictly and purely selfish; and he is nothing loath to seek his self-gratifications at every hazard deemed compatible with his safety, or his *probable* safety; else why your court-houses, jails, whipping-posts and penitentiaries? not forgetting that summary contrivance with which Haman was wont to remove Mordecai from the king's gate? Disguise it as you may, neglect of duty to dear old Mother Earth, to "till and dress her" faithfully, has hatched and now feeds those necessary Vampyres. Nor is this all. Look back upon the whole history of man, and hatred of labor and self-gratification are his ruling passions. He has not always been cannibal; but let self-gratification make it necessary, and he has been ever found ready to take the blood of his fellow, or make him his servant. If, in the beginning, Moses had taught that to "till the earth and dress it" was a paramount duty, divers other commandments would never have been broken. True it is that he did say "whosoever sheddeth man's blood, of him shall blood be required;" and yet we learn that more than ten times the number now living have been slain for the gratification of the selfish purposes of others. If it be the duty of man to till the earth and dress it, and we show him how much self-gratification he will have in the result, surely, though we preach of the resurrection of dead land, we may be heard; for this is the great panacea of church and state. First let the land be made perfectly dry, and lay upon it 50 or 100 bushels of shell or stone lime to the acre, let it lay three months if possible before you plough it for corn, (a shorter time will do,) then harrow down well to close the cracks, and plant in checks or straight lines as may suit the cultivators' fancy, this done coulter the land well, clean the corn with the hoe as soon as it is large enough, passing the cultivator as many as three times in a row five or five and a half feet wide; this keeps the land light and free to the roots of the growing plants, and saves the evaporation of the volatile fertility of the earth; in this way a single horse will well cultivate as much land as will make 100 barrels of corn. For fallow, lime your land in the same manner, and turn it well in May and June, and harrow it down close. After your wheat is thrashed and delivered, throw your land in the desired shape, and keep it clean until seeding time. My life for it, there will be no mistakes; nature never makes any; it is the lazy man who mistakes, and finally cheats himself. I now have a most beautiful field of 100 acres thus prepared, and I am deceived if it be not equal to two crops of clover lay. Let me be understood fully; I take it as granted that every farmer, or every man pretending to be a farmer, makes and applies all the manure he can, his farm affords him a great mass of material, and if he will add to this all the rich earth he can collect, mixing the same with lime, I doubt not he will soon begin to doubt whether he is upon his own miserable tattered estate. I seed my land in clover in February. I think, sir, if I could take you over my fields, you would agree that I was in a fair way to carry out my premises. Court-houses, jails, and penitentiaries, you would see in imagination going into dilapidation, and the very church superseded in half of its moral labors. For why denounce vices that have ceased to exist? Who would practice "coward deceit and ruffian violence," if not urged on by want and envy? From Canada to Mexico we have but one cry, and that is, "stand by your party." If, sir, our fields were covered with abundance, who would dare to raise that cry? Who would dare to raise any cry unfriendly to our beloved country? Where would the wretch hide himself who would dare to declare that "to the victors belong the spoils?" I am no politician, sir, but I stand by my country, and her would I have covered with abundance.

Before I close this, let me say a few words about manure. It is the bread and meat and the money-power of the farmer; without it, he is a poor fellow. Let him therefore keep in mind that as it is his only active capital, his dividends of profits *must* depend upon it. Let him therefore at all opportunities cover his farm-yard with rich earth, and over that apply a good coat of lime; upon this pen his cattle, and so go on through the year, and the quantity he will make will surprise him. If possible let him apply it as surface dressing upon grain or grass; but apply it as he may, it is productive power. Let his motto be "my duty to Mother Earth," and my life for it, dear old Virginia is once more great, patriotic, abundant and happy. Let me say to you, Mr. Editor, that you have no cause to despair; you are acting upon that great and absorbing principle in man, self-love, and you cannot fail.

I bid you farewell, in the name of dear old Mother Earth, whose kindness is only limited by our own acts.

LIME.

Fairfax County, 6th May, 1838.

Extract from the British Farmers' Magazine for April, 1838.

RELATION OF SOILS TO MANURES.

There is an essential difference between sands and sandy loams; the former are greedy of manure, and being almost purely silicious, they decompose it rapidly, and relapse into their original poverty; but loams, though composed of little more than one-tenth of fine aluminous and cretaceous matter, with nine-tenths of silex tinted by oxyd of iron, retain and fix manures; they are pulverizable, reducible to ash fineness, yet cannot be deprived of manure otherwise than by the attractive energy of a vegetable crop. Thus, to borrow the excellent description given of a *naturally* good and rich soil, by an American agricultural chemist:—"After being exhausted by cultivation they will recover their productive power by merely being left to rest for a sufficient time, and receiving the manure made by nature of the weeds and other plants, that grow and die upon the land. * * * The better a soil was at first, the sooner it will recover by these means, or by artificial manuring."

There is one fact which cannot be too strongly impressed upon the purchasers or renters of arable and pasture land, it is this:—that, be the natural quality of the staple what it may, it remains permanently the same! Poor, beggarly land may be glutted with manure, but *that* is evanescent: the more hungry the native earth, the more speedily will it become exhausted. By parity of reason, it may be shown, that *rich land* may be deprived of its decomposable manures, and by a wretched parsimonious management can be prevented from exerting its decomposing powers,—that is, it may be rendered inert and idle, but its native inherent worth can never be depreciated, and hence he who purchases good and sound land, embarks his property on a venture which must be prosperous, if he act upon the principles of a liberal philosophy, which will teach him that *the decomposition of putrescent manures in soil* is brought *about by a mutual energy exerted between the vital principle of the roots*, and the staple *undecomposable native* earths. This energy is not remote from that of the galvanic battery; and when we become more conversant with the powers of electricity and magnetism, we shall feel ourselves proportionally enlightened upon the points, now involved in mystery, connected with the laboration of vegetable aliment. My own mind is satisfied thereon; but, in the absence of incontrovertible evidence, we must wait the progress of further discoveries.

From the British Farmers' Magazine.

USE OF FISH MANURE IN ENGLAND.

The fish which are usually employed as manures, are, 1st, sprats; 2dly, pilchards; 3dly, herrings; 4thly, sticklebacks; 5thly, whale blubber. These are very rich fertilizers; the fleshy or muscular portions abounding in oil. The scales are composed of coagulated albumen and phosphate of lime; the bones are full of oil, and their solid portion is composed of phosphate of lime and carbonate of lime, in different proportions.

Sprats.—In the counties of Essex, Kent, and Suffolk, the use of this manure is very general, although the practice is not of very long standing. The quantity applied per acre varies from 25 to 45 bushels, the poor gravelly soils requiring more than the loamy lands.

They are actually spread by hand, and on winter fallows intended for oats, of which, especially if the summer is not too dry, it produces most luxuriant crops, of a peculiar dark green color, yielding ten or eleven quarters per acre, and that on land of a very second-rate description. The effect of the application, however, remains only for one crop. They produce an equally good result if mixed with earth and suffered to remain and dissolve, for some time, in the heap, before they are carted on the land. In this way they answer exceedingly well for turnips. They are usually obtainable at the rate of from sixpence to eightpence per bushel.

The extent to which this manure is used may be judged by that of the Stow-boat fishery, which is solely devoted to catching fish. Upon this fishery the committee of the House of Commons of the session of 183[?] thus reported—

"This fishery, which prevails principally upon the Kentish, Norfolk, and Essex coasts, has been proved to your committee, to occasion very extensive injury to the spawn and brood of fish. The nets used in it are of a very fine description, so small as not to let a pea pass through, and they enclose not only sprats, but the spawn and young brood of all other kinds of fish, and as these nets are frequently drawn along the ground, and in shallow waters during the breeding season, and in the winter months before the young fish are gone into deeper waters, an immense destruction of the spawn and breed of fish is the inevitable consequence; whilst from the almost unlimited demand for this species of manure for land, and there being a ready sale for all that can be procured, this branch of fishing has greatly increased; and there are at present from four to five hundred boats engaged in Stow-boating on the Kentish coast only, which remain upon the fishing grounds frequently for a week together, not for the purpose of catching sprats or any other fish to be sold as food in the market, but until they have obtained full cargoes of dead fish for the purpose of manuring the land."

The farmers of Essex and Suffolk purchase these fish by thousands of bushels at a time, and carry them in wagons ten or fifteen miles into the inland districts.

Pilchards are extensively employed in Cornwall and Devonshire, both in the fresh and in the salted state. The pilchard is a small fish not larger than a herring; it visits part of the coast of Cornwall and Devon in large shoals, during the months of August and September, and again in November or December.

The refuse fish, which are those principally used by the cultivator, are usually mixed with earth, sea-sand, sea-weed, or some other substance, to prevent them from causing too rank a growth. The effects of these pilchards, according to Sir H. Davy, are apparent for several years.

The pilchard is a very oily fish, and may be had in almost inexhaustible quantities. Between eight and nine thousand persons, at sea and on shore, are employed in this fishery, and about 30,000 hogsheads are annually exported either to the West Indies or the Mediterranean.

The Herring.—The employment of this valuable fish for the purpose of manuring the ground is limited to those districts near the sea, to which the shoals of herrings are regularly visitors, and even there, their use is confined to those seasons in which there is an unusual glut, as occasionally happens on the coasts of Scotland and the eastern side of England. They are a very oily fish, and produce the same rank luxuriance of growth as sprats or pilchards.

The celebrated Arthur Young has given us an account of an experiment, in which some wheat, manured with these fish, grew so luxuriantly that it was entirely laid before the period of harvest.

Very numerous or accurate comparative experiments with this fish can hardly be expected, for its use must necessarily be confined to peculiar districts; and when obtained, it is generally ploughed in with considerable expedition, or dug into earth heaps, which is a mode found to answer extremely well.

Sticklebacks.—The use of the stickleback is principally confined to the neighborhood of the Fens of Lincolnshire and Cambridge, in which it breeds with great rapidity, and in whose shallow waters they are caught at certain seasons, specially as an article for manure. They are used in much the same proportions, either by themselves or mixed with earth, &c., as sprats, and are not more durable in their good effects.

The fat or blubber of the whale.—Whale blubber was employed by the late Lord Somerville, at his farm at Fairmile, in Surry, as a manure, and produced the richest crops. Its general high price, however, rarely admits of its employment by the farmer. It was mixed with the sandy earth, and suffered to dissolve in the heap. It cost, at the wharf in London, 20s., and, with the expenses of carriage, cost his lordship about £2 per ton. It answered equally well upon arable and pasture lands, producing most luxuriant crops; and its good effects were visible for two or three years.

Whale blubber is composed principally of train oil and other animal matters; but the oil is by far the largest portion of the blubber; and to the presence of this fish oil, which does not appear to differ materially in composition, from whatever fish it is obtained, must be attributed the chief fertilizing value of all fish.

Train oil has been analyzed by Dr. Thomson. He found in 100 parts—

Carbon	-	-	68.87	
Hydrogen	-	-	16.10	
Oxygen	-	-	15.03	
				100.00

Spermaceti oil, according to Dr. Ure, contains in 100 parts—

Carbon	-	-	78.00	
Hydrogen	-	-	11.80	
Oxygen	-	-	10.20	
				100.00

Fish oils, therefore, are composed of exactly the same substances that constitute almost all vegetable substances, differing only in the proportions for sugar, starch, gluten, gum, &c., &c., which are all composed of these three substances—carbon, hydrogen, and oxygen; blubber, therefore, may be regarded as the most condensed manure that it is possible to apply to a soil: it contains little, if any, water, and every portion of it is a food for plants.

The same remarks will apply to the dregs of train oil, &c., which are sometimes applied; mixed with earth, to the same purpose; but it is seldom that these substances can be procured in any quantity, at a sufficiently reasonable rate.

Some farmers may possibly doubt the correctness of my assertion, that all the principal vegetable substances are composed of precisely the same ingredients as oil and other purely animal matters; and as it is of the first importance that the cultivator should clearly understand the reason why the decomposition of animal matters furnishes such admirable food for vegetation, I must beg of him to compare the analysis of the oils which I have already stated with that of the following common vegetable substances, as ascertained by the most careful analysis; and, not to be tedious, I will merely give that of three substances:—

1. Sugar, 100 parts of which are composed of—

Oxygen	$51\frac{1}{2}$	parts.
Carbon	$41\frac{1}{2}$	"
Hydrogen	7	"
	100	

2. In 100 parts of starch from wheat flour are found—

Oxygen	$49\frac{1}{2}$	parts.
Carbon	$43\frac{1}{2}$	"
Hydrogen	7	"
	100	

3. The wood of oak is composed of—

Oxygen	$42\frac{1}{4}$	parts.
Carbon	52	"
Hydrogen	$5\frac{3}{4}$	"
	100	

All oily and other animal substances, therefore, as they putrefy in the soil, are slowly converted into those gaseous substances which are the food or breath of vegetable life, such as carbonic acid, gas (fixed air) or carbonated hydrogen (the gas employed for illumination), and which are absorbed either by the roots or the leaves of the plant as they are formed. There is little or no waste, in these, for when the decomposition of the oils and fibrous matters of fish is finished, there is very little or no earthy or solid matter remaining, unless in the soil. In this, again, the experience of the farmer substantiates the chemist's doctrines, for he uniformly tells us in answer to our inquiries, that "the fish only last for one crop."

In the east of England the farmers of the soils conveniently situated for water carriage employ to a very considerable extent as manure several kinds of fish besides sprats, such as five fingers, cockles, muscles, &c., and this use is only limited by the supply, or what is commonly a more important impediment, the difficulty of transporting them any distance while sufficiently fresh.

When once the fish begin to putrefy, their fertilizing properties rapidly diminish; the oil from the fermenting sprats I have seen dripping from the wagons as they travelled along; thus they speedily lose in weight, and become intolerably obnoxious to the district through which they pass; several convictions have, indeed, taken place among my neighbors in Essex, for carrying putrefying fish through towns and populous villages.

This is hardly a matter of astonishment, since the farmer who has to convey a freight of several hundred bushels of sprats, perhaps ten or twelve miles, has often much too little time allowed him for that purpose. The fish perhaps arrive stale. Is a load detained by contrary winds, or prevented by circumstances from reaching another destination, the farmer has to be informed of their arrival, cannot despatch his teams as speedily as the nature of the case requires, the fish become offensive, and his ardor for the improvement of his land is checked by a magistrate's summons and a conviction for a nuisance. These are the reasons which retard the use of these kinds of fish as manure, but cannot entirely prevent their being employed. Their use is still, in spite of all impediments, annually increasing, especially in the neighborhood of those places to which the fishing smacks find a ready access.

By the general formation of railroads, the cultivator even of the inland soils of England will have all these valuable sources of improvement offered for his service—fertilizers of even national interest, since they are drawn from an inexhaustible source, afford employment to a branch of industry invaluable in a maritime point of view, as a nursery for seamen, and have, moreover, this great and paramount advantage, that they add to the permanent riches of the land, and are not, as is the case with other fertilizers, drawn from one district of the state to enrich another. There need be no fear of the supply not keeping pace with the demand, for the ocean is inexhaustibly tenanted with fish. As fresh agricultural markets arise and are satisfied bythe railways, fresh sources of supply will be discovered, other coasts explored, and increased fisheries established.

From Miseries and Beauties of Ireland.

THE PRICE OF RENTS, AND OF THE TENANTS' "GOOD WILL" IN IRELAND.

"The circumstance that would strike an Englishman as most remarkable on first investigating the agriculture of Ireland, is the enormous price given for the tenant-right or good-will of a farm, in addition to a full and sufficient rent. Ten pounds per Irish acre is no unusual price. This cripples the farmer, and keeps him in debt as long as he lives. Nor is the practice confined to farms held under lease; those held from year to year are purchased; and, if belonging to a kind landlord, fetch nearly as much as those held on lease, though the tenant is liable to be turned off whenever the landlord chooses. Such is the confiding disposition of these people, when the conduct of the landlord, whatever be his politics or religion, is regulated by honorable principles. This confidence in their superiors is one amongst many proofs of the docility of the Irish people, and the ease with which they may be governed. I was anxious to ascertain how these farmers, always poor and in debt, could possibly raise the money to buy the farms. This I never got satisfactorily answered, and I believe they scarcely know. Some go to England and earn money by trading, shearing, and other work. They borrow the greatest part by becoming sureties for each other; in this they exhibit great kindness. Under this system of paying tenant-right, the landlord has always security for his rent, even supposing the stock to be driven off, because he would take advantage of the property which the tenant had in the farm, and the new tenant always pays the arrears of rent, the balance only being paid to the off-going tenant. It has also naturally induced the tenant to consider that he has a beneficial interest in the farm; the practice, by long usage having assumed the character of a right—so much so, indeed, that in some places, (the county of Donegal, for instance,) a tenant, I am told, sells his interest in his farm in spite of his landlord. A father leaves it by will to his children, or gives it whenever he pleases, and it passes by will like real property. This may account for the peculiar hardships the people feel, and the way in which they prosecute their revenge against the landlord, or his steward, and the incoming tenant. In many parts of Ireland the difficulty consists not so much in dispossessing the present tenant, as in securing peaceable possession for his successor."—Vol. i, pp. 84—86.

"Small farmers pay their rent in money; laborers generally in labor. The competition for small holdings, single acres, &c., causes the tenantry to bid any thing in order to get in. 'If a farm of five or ten acres,' said Thomas Rogan, 'were vacant in the barony, there would be dozens of bidders for it.' This witness occupied a farm of three acres and three roods Irish, for some of which he paid £1 5*s.* per acre, and for more of it £3. 'If you were going away,' he was asked, 'what would you expect for the land?' 'I dont think I'd leave it under £60 or £70,' was his answer. Mr. Trotter, one of the witnesses, had known £170 to be given for a farm of Lord Downshire's, at Ballykanly. The land was six acres, at a rent of £2. 2*s.* per acre; this value was set upon it, not because it was building ground—it was a common farm. The same witness stated a case where £100 per acre was given for six acres (Irish measure) paying 10*s.* 6*d.* an acre rent; this, however, was in the war time.

"When the tenant gets a year or two in arrear, the landlord, instead of ejecting him, allows him to sell his 'good will,' on condition that so much of the purchase-money as will clear the arrear be given to himself. Of those thus got rid of, some, said Mr. Gracey, go to America; but the majority repair to towns with the remainder of the money, and set up business—generally a public-house. It did not appear from any of the witnesses that a single penny of rents is reduced in case of a hard year; and yet it seemed that the anxiety to obtain land, even at a high rent, increases, as the means of paying the rent diminishes. From all that could be ascertained, the farmers now give every thing towards the rent, except a bare subsistence. 'People, in fact, are mad after land, and in the bargains respecting it, the landlord is sure to be on the winning side.' It was stated however, that Lord Bangor, in letting some ground lately, refused the rents that were offered. He sent out his valuator, and though several offered considerably above the valuation, his lordship did not accept of any advance upon it. The witness who furnished this information stated also, that rents in general were increasing; that the average in the vicinity of Strangford was about 25*s.* per Irish acre; the cess 4*s.* per acre; and the tithe, 2*s.* 6*d.*

"The average extent of farms is about twenty acres Irish; there are very few exceeding one hundred acres. The size of the holdings has rather increased than otherwise. According to the statement of Lieutenant Martin, there is only one dairy farm, properly so called, in the barony. Those proprietors who have attempted to enlarge their farms have incurred considerable odium; the farmers would as soon part with their lives as with their farms. When a man is in arrear, the landlord causes him to sell his farm, and is anxious that some adjoining farmers should purchase: this was stated to be the usual course. 'I myself,' said one of the witnesses, 'commenced the world on seven acres, but by hard labor and care I have purchased up to forty-one now.' 'One of my neighbors,' said Mr. Gracey, 'began on nine acres, and by strong industry he has purchased £600 worth of land.' All the farmers agreed that if a farm of fifty acres were divided into five farms, more would be produced than if the whole were in the occupation of one man: more care and labor can be devoted to it. There is a wonderful competition for farms of all sizes, of which Captain Saunders gave us an instance. 'A tenant of Major Beauclerk's,' said he, 'some time ago bought ten acres in addition to his own farm of forty, at a very high rate. I told him at the time it would be his ruin, because he had to borrow some of the purchase-money; and so it turned out. He came to me the other day, wanting to sell it again, in order to pay up his arrear: and what do you think he was offered for it? A neighboring tenant offered £200 for his 'good will;' for the ten Irish acres are out of lease. But I refused to permit the bargain to be completed, knowing that it would only break the other man, inasmuch as he also would have to borrow most of the purchase-money. I only consented to the sale on condition that the purchase-money should not exceed £50. The ten acres paid a rent of £2 2*s.* an acre.' "—Vol. i, pp. 113—118.

Extract from the Rev. H. Colman's Report on Spring Wheat.

MANURES FOR WHEAT.

Land among us can seldom be found too rich for wheat; but the enriching manures may be applied in too great quantities; or in an improper condition; or at an improper time. The feeding of plants is as imperfectly understood as the feeding of animals. As with animals, so with plants, we know that they cannot live without food, and their vigor and fruitfulness depend much upon the quantity and quality of their food. But how it is taken up, and by what means elaborated and distributed, remain as yet, in a great degree, among the deep secrets of nature.

Manures are of two kinds; putrescent, animal, or such as are supposed to furnish directly the food of plants; or active, such as excite either the organs of the plant to receive, or the powers of the earth to prepare, this food to be received, or by themselves educe from the substances, with which they come in contact, the means of sustenance and growth for the vegetables to which they are applied. The former class consists of animal or vegetable substances in a state of putrescence or decay, the latter, of mineral substances capable by their action of rendering these vegetable and animal substances soluble and receivable.

I shall go little into any theory of vegetation or of the operation of manures. Many theories have been framed, but no one so demonstratively established, that none other can be substituted in its place, after farther inquiries shall have made us better acquainted with these mysterious but profoundly interesting operations of nature. Facts established by repeated experiments, are mainly to be relied upon. The application of green and unfermented manures has always been prejudicial to wheat crops. We know that the food of plants cannot be taken up unless it is reduced to extreme fineness or rendered soluble. This is applicable to all plants. If green and unfermented animal or putrescent manure be applied to wheat, it is always advisable to plough it in deeply, so as not to be reached by the roots of the plant until it has undergone some degree of decomposition. If, however, the manure be completely fermented and decomposed, it may then be safely applied, by being spread on the ground and harrowed in. It is desirable, however, in general, that the manure should be applied to the crop which precedes the wheat.

Lime.—The presence of lime in some degree in the soil, seems essential to the growth of wheat, and in a degree to the perfection of any plant. A very minute portion of lime is always found in the wheat plant. Some portion of lime likewise is found, it is believed, in all soils, excepting those composed entirely of decayed vegetable matter like peat, or of pure silex or sand.* In the most productive soils for wheat, lime is found in the form of a carbonate; and the permanent value of a soil for grain crops may be in a degree determined by the presence of lime. In Europe, the analysis of the best soils gives 25 to 30 per cent. of carbonate of lime.† We shall soon be favored with the analysis of the soils of our own state from our learned geological surveyor.

Lime is not however the food of plants. It is not a mere stimulus to the plant. The most reasonable theory is, that it causes the dissolution of other substances in the earth; and prepares them to become the food of plants, or to yield that substance which constitutes their food. As lime itself does not constitute the food of plants, this explains why lime alone does not enrich a poor soil; and why, where it has been applied in excess and without the addition of other manures, it for a time impoverishes a soil.

A new theory of vegetation has been suggested by some distinguished European philosophers, which professes to approach nearer to a solution of this great mystery than has yet been reached. "A new substance has been discovered in all soils and manures, which is denominated *humin* or *geine*. It has been found likewise in all barks; in saw-dust, starch, and sugar. Humin is a substance not unlike carbon, for which it has hitherto been mistaken. It combines with the salts and forms the humic acid. There is a strong analogy between humin and other nutritive substances, such as gum or fecula. It forms a humate with an alkali, which is very soluble in water. All substances which contain carbon, are dissolved in the water of vegetation through the means of humin; and the dissolved mass is taken up by plants as food. Humin in combination with lime, ammonia, or potass, also becomes soluble in soils or dung. Humic acid, and carbonic acid gas, mixed with water, according to this discovery, constitute the chief food of plants. Every description of manure is only valuable in proportion as it contains these substances."

Such is the modern theory of vegetation; which is in itself plausible, but which will be farther tested by the lights of chemical science; from which examination the best results to agriculture are to be expected. Lime causes the evolution or extraction of this matter from various substances. Potash leads to similar results, and with more power than lime and bone manure; and night soil and all animal manures are supposed to furnish humin or geine in abundance. In respect to night soil or human excrement, a discovery has been recently made in France, which promises valuable results. The charcoal procured from burning wood, peat, or coal in close vessels has been mixed with it in the form of a fine powder, which operates to disinfect it of all offensive odor; and reduce it to a powder, which is portable and may be easily distributed. I have seen this process perfecty effected in the course of an hour. Manures in a decomposed and fermented state, are said to supply this humic acid much more abundantly than in a crude or fresh state. In what precise condition they are best applied must be matter of farther inquiry and experiment; and depend somewhat on the mode of their application. If designed to be spread broad-cast and ploughed in, experience seems decidedly in favor of applying them in a green and unfermented state; but it is as well decided that green and unfermented manure should never be brought in immediate contact with the roots of a growing plant.

The rules for the application of lime to the soil, are of more immediate importance to the farmers than any further discussion of the theory of their operation.

Limes are found of various qualities from their different measures of combination with silicious, argillaceous, or magnesian earth. Magnesia is found combined with some of our limestones in considerable quantities, and when in great amount is deemed prejudicial to vegetation. The quality of our various limestones is of great importance; and this will soon be furnished to us by the highest authority. Lime may be applied to soils for two objects. The first to make a permanent change in the nature of the soil, as for example, to render a clayey soil less adhesive, and make it

* Which need not be stated as exceptions, as neither pure silex, or vegetable matter alone, deserves to be called "soil"—to constitute which more than one ingredient is always required.—Ed. Far. Reg.

† And in all our Atlantic States, not one acre in 100,000 has even one per cent. of carbonate of lime. Still Mr. C. is correct in saying that some small portion of lime is in every soil (properly so called)—and a larger proportion is as certainly a part of every *fertile* soil.—Ed. Far. Reg.

friable. In this case, a very abundant application would be required; and at the present prices of lime and of land, would be an experiment not likely to be undertaken by many of our farmers.

The second object is to afford immediate aid to vegetation. In this case, if we had means of reducing the limestone to a fine powder without calcination, it might at once be advantageously applied, and with permanent benefit. This has been done by an intelligent observer in West Stockbridge. He has obtained the ground stone in the form of a fine powder from the mills and shops for sawing and planing marble. The usual form in which lime is to be applied among us, is in a calcined state, and with a view to its immediate effects. In order to apply it advantageously, it must be either air-slaked, or slaked with water. It may be slaked with water in the field, and distributed immediately while warm; or mixed with mould, in the proportion of one bushel of lime to five of mould, and spread in that form; in which latter form it is, perhaps, more likely to be equally diffused. It may be mixed with peat earth; but in this case it should be allowed a considerable time for fermentation, in order to render the vegetable matter of peat soluble, and to extract from it the proper food of plants. But it must not be mixed with animal or putrescent manure. Its effects in such case are to destroy the animal matter, and leave only the woody fibre.

The effects of lime, whether applied in a caustic or an effete state, either air-slaked or water-slaked, are not very different. The heat imparted to the soil by its application when warm, would undoubtedly be to a degree beneficial. It should be applied on the surface of the soil, and merely harrowed in. It has a constant tendency to sink into the soil: and its operation is wanted in the vegetable mould, which is at the surface. In regard to the quantities to be applied, there are great diversities of practice. In England, upon soils comparatively destitute of calcareous matter, from 100 to 600 bushels have been applied; the last quantity, however, with injury to the land for some time. The English consider that 300 bushels are ordinarily a proper dressing for an acre, and this is applied at once; very much larger quantities have been applied, but the advantages of such copious liming are not always a compensation for the expense.

The French, and the Germans, of late especially, have been highly successful in the application of lime. The practice of the former differs from that of English agriculture; but its advantages have been fully tested. They recommend the application of about 12 bushels per year, annually, for three years in succession, or 40 bushels applied at a time once in five years. This is deemed ample. In this case is probably intended 12 bushels of unslaked lime, the bulk of which in the form of a hydrate, or slaked with water, is more than doubled. The plants on an acre will not take up a sixth of this quantity; but much of it is lost by gradually sinking into the soil, or goes to its permanent improvement. The French method rests upon the highest authority of science and actual experiment; and may be commended to our farmers.

Marls, which contain a good proportion of lime, are of great value in ameliorating soils; and operate in improving soils and supplying calcareous matter, though not in the active and immediate manner in which lime operates. Their application, however, is considered by many as preferable to lime. On this subject we want more experience. The Berkshire shell-marls, which have been recently discovered, contain from 80 to 90 per cent. of lime. The operation of shell-marl, or marl containing a large amount of shells in a state of decomposition, is much slower than that of quick lime; but its effects are quite lasting. When applied to heavy soils and soils naturally cold, it enriches vegetation, but does not forward it.

Potash, or vegetable alkali, is stated to be of more value than lime in producing the humin which is deemed the essential food of plants. Some value it at a much higher rate. It has been applied at the rate of from 50 to 100 lbs. to an acre; and, as stated, with great success; but I have no knowledge of any such decisive experiments as would justify me in speaking with confidence of its effects, or the mode of its application. Mr. Williams's great crops of wheat have been assisted by fifty bushels of wood ashes spread to an acre; and a good crop of wheat seldom fails to be obtained on newly cleared and burnt land. The potash is here present in large quantities.

Leeched ashes and soapboilers' waste are esteemed a most valuable manure. A good deal of lime is ordinarily mixed with them; and they abound in vegetable alkaline matter, which is highly favorable to the crop. They should be spread on the surface, and harrowed in. From fifty to one hundred bushels can be safely applied to the land, though few farmers will feel that they can afford the application at the prices at which they are at present held. I have used them with great advantage; and one great advantage from the use of bone manure and ashes is, that they do not introduce weeds into the soil. The farmers on Long Island often import leeched ashes from New England for their wheat lands; and, as they say, with much advantage. They must not be too often repeated on the same land.

Bone Manure, in the form of dust, or small pieces and dust intermixed is a most valuable manure. It contains a large proportion of the phosphate of lime, which has always proved a most efficient aid to vegetation. Forty bushels of crushed bones, or twenty-five bushels of bone dust, to an acre, have been found as efficient as a much larger quantity; and no advantage whatever has come from doubling this amount. Bone dust mixed with ashes has been highly efficacious. The best mode of application is to mix them with mould, or barn-yard compost; and if for grain crops spread and harrow them in lightly; but it is essential that they should undergo a degree of fermentation before they are applied to the land; and that the land to which they are applied should be dry. The lands on which bone manure has been found efficacious have been light, dry, and sandy soils:—upon clayey or heavy soils it has not been useful. If for immediate effect, the bone dust is to be preferred; if for permanent improvement, the crushed bone. At the only mill known in Massachusetts, which is at Roxbury, the manufactured article contains a good deal of the dust intermixed with the crushed bones. It is sold here, we understand, at 35 cents per bushel, and large quantities are on hand to be supplied.

The application of lime, too, should never be made but in dry weather, and when the land is dry; as otherwise it is apt to be formed into a mortar, which is not easy of solution. Lime applied in any form to the land, it is to be remembered, is not an enricher of the soil; and therefore, if lime alone should be applied for a succession of years, and all putrescent or vegetable manures be omitted, the land would be losing instead of advancing in fertility. It is merely a preparer or evolver of the food of plants.

Gypsum has not been found of any apparent value to wheat.

Saltpetre. Another manure, never, we believe, used in this country, from foreign accounts deserves a trial. This is saltpetre. It has been used at the rate of one cwt. to the acre, finely pulverized, and sown broadcast upon the growing crop; and its beneficial effects upon the plant are stated to have been remarkable, especially in its effects upon the straw. It is to be used, however, with caution, as not having been sufficiently tested.

From the American Turf Register.

TAMING WILD HORSES.

Having announced some months since, that the editor of the Turf Register had become possessed of the secret for taming wild horses, some publication of the results of our experiments has been of course expected, and we now proceed with a statement of facts. We must premise, that there is no man who detests quackery in all its forms, or that abhors more thoroughly the witchery of *charms*, then does the writer of this. It was this contempt for empiricism, that kept him for some years from even listening to the reports of 'taming wild horses' in a few minutes, by aid of some secret means; and when the high respectability of the reporters was forced upon him as a voucher for the correctness of the reports, the same feeling compelled him to attribute those wonderful results, to delusion, to the practice of which, respectable men are as liable to become the dupes as any others. At length, a report came from a source which could not be doubted, either on the score of respectability, or the supposition of delusion—the reporter practised with his own hands, and witnessed the results with his own senses, (see Turf Register, vol. viii. page 261, 262, 263, and 500.*) We then determined to obtain the arcanum and try it ourselves. We have done so, and we are convinced. We shall now state a few facts. Having had no opportunity of course to try it on *wild horses*, our experiments have been confined to balky horses, and we have had but three chances even with them, and they were accidentally met with, and of course we were not *duly* prepared. A friend was found in the street with one of his carriage horses refusing to go. It was an old trick of hers, (it was a mare,) and in a ride of two miles, she had stopt several times, laid down in the road, and acted the stubborn and sulky brute in all its characters. When we found him, our friend was stuffing the animal's ears with soft paper; he had whipped the brute till he was tired, the paper was speedily shaken out by the animal. We approached the mare, asked our friend to desist from further efforts, saying the mare would go presently, at the same time applying the arcanum slightly, but not perceptibly to any of the bystanders. In less than ten minutes, I told my friend I thought she would go; he took the reins, she went off handsomely, travelled seven or eight miles out, returned in the evening, and exhibited no more signs of balking. We have not heard whether the animal has balked since; but should not be surprised if it did, as the operation was very slight and imperfect, from our not being properly prepared. The other two cases were both alike precisely, at different times. They were horses with heavy loads of wood on carts at the foot of the long hill in Charles street. We found the drivers whipping and beating them with the but-end of their whips over the head, and the horses in a perfect frenzy from fear. We prevailed on the drivers to rest the horses, put up the shafts, approached gently their heads, patted them, and applied the acranum slightly, (being unprepared.) In about five minutes the horses were perfectly composed, and we then told the drivers to take the reins, and start them, but not to let the horses see the whip. They both started handsomely, went up the hill to the top with perfect ease, and without the slightest symptom of a balk. The crowd of negroes standing around were greatly surprised, and expressed their feelings in loud tones. Now, in relation to all of these cases, it may be said, that the change of treatment from an extremely severe, to a mild and conciliatory course, would naturally produce the same result, and therefore, we are not left to the necessity of attributing it to a cause so mysterious as the pretended arcanum. We confess these were precisely our own reflections almost reduced to conclusions, until we had an opportunity of applying the same treatment *without* the arcanum, which had no effect whatever; and before we could return and supply ourselves with the remedy, the horse had been taken out and sent away. But a gentleman on the Eastern Shore of Maryland, has made four experiments with it, much more satisfactory and important than our own. We shall give the description of them in his own words, premising that there is no gentleman in our state who stands higher in the estimation of good men than he does.

1*st Experiment.*—"I have a horse that had stopt at a particular hill two or three times. In every other respect, perfectly gentle and kind. When I got to the hill the horse halted, I got out, applied the arcanum, gave him the word, and he moved off instantly. It appeared to me, that he went with more spirit afterwards than usual."*

2*d Experiment.*—"My next experiment was on a *bull.* It was for the most part satisfactory. We had to throw a rope around his horns and draw him up forcibly to a post and secure him. For some time pending the operation, he made the most violent efforts at intervals to break loose, but in vain. I discovered that he was pinched severely by the rope about his head, and on relieving him from the pressure, he soon yielded to the influence of the arcanum. A yoke and bow were

---

* See Farmers' Register, p. 481, vol. 5.

* This horse balked afterwards with another person. The remedy has not yet been tried on him thoroughly.

placed on his neck and he was put in the shafts of a cart alone, and driven a mile out and back, and was perfectly tractable. The two negroes who had hold of him were perfectly astonished. The following day, however, he became sullen, but was gentle to handle, would go a little way and then fall flat on the ground, but was in no way vicious. The third day he exhibited the same sullenness, and after various means had been resorted to, to move him, some straw was placed along side of him, and fire applied to it; as soon as the blaze reached him, he jumped up and went to work honestly. He has fine spirit, can be approached every where, and handled with perfect gentleness—he never laid down after the firing, and never from the first showed any bad symptoms but the one of being sullen."

3d Experiment.—"The next trial was on a fine four-year-old mule. A partial attempt had been made to break him last summer, but he kicked every thing to pieces, and I determined to wait for the secret. He was exceedingly vicious, and difficult to approach. We finally succeeded in barring him up in a stall, and getting a bridle on, and securing him properly. The operation commenced by very slow degrees and great caution. He twice got over the bars of the stall with two powerful men holding on to him. You will understand, that his position was reversed, his rump was against the manger, and two bars were put across the stall, resting against the post, the upper bar as high as the top of his back, and to my astonishment he got over, but did not get loose. It was a long time before the arcanum took effect, and I had absolutely begun to despair. A violent storm of wind and rain came on during the operation, and I was much troubled what to do; but just as the rain abated, he began to yield; we could then handle him any where; the gear was put on him, he was led out and put in the shafts of a light cart, the wind blowing terribly, he moved off finely, was driven out several miles and back; taken out, fed, and after dinner, eight or ten light loads of manure were hauled by him. He is true to the draft, has prodigious spirit, and works well in a cart; he has, however, kicked a few times. This mule could probably never have been subdued by the ordinary methods."

4th Experiment.—"I broke another mule of the same age as the above, this evening, with about one-fourth part as much of the arcanum as was used on the preceding."

It is proper to remark, that the same gentleman tried the remedy on a fine blooded mare last winter, and failed to produce any effect, or if any, very slight. But believing that circumstances prevented a full and fair trial, the report of her case is deferred until another effort is made.

In relation to the experiments above reported it is also proper to explain that the sullenness of the bull might probably have been overcome by the application of the arcanum, though the firing was equally as easily applied. As to the prolonged and tedious operation on the mule, in the third experiment, the cause is perfectly apparent to us, and we were surprised that it did not occur to the very intelligent operator. It was the violent *wind.* We cannot with propriety explain the *modus operandi* of this cause in this place, but it will be perfectly plain when suggested to those in possession of the arcanum. The weather should always be perfectly calm during the operation, or the animal should be placed in a stable perfectly closed against its effects. It was not, we think, the devilishness of the animal, that resisted such persevering treatment, but the unfair chance the treatment itself had of being effectual.

Now let us ask all persons acquainted with horses, to examine the above cases candidly, and to refer to the statements of 'Signa,' (above referred to,) and then say whether there is any delusion in the 'secret for taming wild horses.' Next to the evidence of our own senses, is the testimony of reputable men; but we surely cannot resist both. We know the magnitude of the draught we are making upon human credulity; but are we not armed with a force that at least authorizes the attempt? We know full well that the present received system of philosophy, will reject even all the testimony we have adduced, because "the why and because" are not developed—because the philosophers cannot trace the effect to the cause, or because an effect is said to be produced by a cause not heretofore recognized! But we will venture to place before them, a still more formidable stumbling block. This singular effect is produced by causes heretofore held by philosophers to be utterly *powerless!* Though they have been known, perhaps, for hundreds of years, and used by millions of people, with the thoughtlessness of thumbing a nosegay, none but the initiated few ever suspected the power of the toys they were playing with. Physicians do not recognize in them any medical effect whatever, (nor are they mentioned in their books,) and yet the writer of this believes them to possess a power over the animal economy, superior to that of any received practice. *How* they operate the writer has not fully made up his mind upon, but he thinks from the few observations he has been able to make, that they effect a complete change in the nervous system, rendering the animal proof against nervous irritation of all kinds.

The most unpleasant circumstance connected with this great remedy is the necessity we are under of keeping it secret. The few persons who possess it, have obtained it under solemn pledges that it should not be published, and paying considerable sums. We have the privilege of communicating it to individuals in our discretion, but not to authorize them to divulge it to others. This circumstance of secrecy gives it the appearance of a speculation, and causes doubts as to its value. As soon, however, as all interested, shall have been *indemnified*; we have hopes of getting the privilege of publishing it, and we pledge ourselves to the public that we shall omit no effort to accomplish the object.

REAPING MACHINE.

The *Mémorial de l'Allier* mentions a very simple and ingenious machine, which had just been examined, the aim of which is an increase of produce to the cultivator, with less labor. Its other advantages are, the simplicity of the mechanism, the facility of construction, and the moderate price (15 francs at most.) Two sickles, seven or eight pieces of wood, some semicircles *(demi-cercles,)* and two yards of cloth, compose the materials. The corn is cut by the play of the sickles in a breadth of 4 ft., and at the desired height. *(L'Echo du Monde Savant, Dec.* 13, 1837.)

From the National Gazette, October 6th, 1836.

TOBACCO TRADE.

It was desired by several of our friends, who are largely interested in the trade of tobacco, that we should endeavor to obtain and forward to them a statement of the exports of that article, and of its various kinds, viz.: Ohio, Kentucky, Maryland, and Virginia, for a series of 15 or 20 years, to enable them to form some opinion as to the probable increase or falling off of the consumption of tobacco, and of the particular description increased or diminished in consumption in particular countries. Such a statement would not only be highly useful to dealers, but also to planters; but there are no data from which it can be compiled, as the records of exports seldom or never designate the description of tobacco exported. In the course of our efforts to obtain the desired information, we became possessed of all the facts relating to the growth and exportation of tobacco which are to be obtained from the records of our own country, and the published documents of others, so far as they were accessible.

A letter of the Governor and Council of Virginia, dated James City, January 20th, 1622, says, "that there was not above 60,000 pounds made in the colony;" but in 1639, only 17 years afterwards, the Grand Assembly passed a law, which recites, that, "Whereas, the excessive quantity of tobacco of late years planted in the colony, has debased the quality," and enacts, "that all the tobacco planted this present year, and the two succeeding years, in the colony of Virginia, be absolutely destroyed and burned, excepting and reserving so much in equal proportion to each planter, as shall make in the whole just the quantity of 120,000 lbs. of tobacco, stripped and smoothed, &c. In consideration whereof, the creditors of the planters were compelled to "accept and receive 40 lbs. of tobacco so stripped and smoothed, in full satisfaction of every 100 lbs. now due them." It is not important to ascertain whether this law was re-enacted at the end of the 3 years named in it; for we find in an official report to the commissioners, that the yearly exports of tobacco for ten years ending in 1709, were 28,868,666 lbs. of which 11,260,659 lbs. were annually consumed in Great Britain, and 17,598,007 lbs. in other countries of Europe. In 1744--1776, the average annual exportation was 40,000,000 lbs., of which 7,000,000 lbs. were consumed in Great Britain, and 33,000,000 lbs. in other European countries. The annual average exportation from 1768 to 1770, both inclusive, was 67,780 hhds. of about 100 lbs. each, or 67,780,000 lbs. As we have now approached the period when the exportation of tobacco arrived at a point from which it has vibrated, (sometimes a little above or below it,) we subjoin a statement of the exportation for the years 1772-1775, inclusive, which will furnish the remarkable fact that (compared with any succeeding four years since that period) the annual exportation of tobacco just before the revolution, was about the same that it has been at any time since, in our most prosperous periods. For although 1790-1792 were three years of very heavy exportations, they fell off in 1793 nearly one half, making the annual average exportation not materially different from 1772-1775;

Statement showing the quantity of tobacco exported from the United Colonies from 1772 *to* 1775 *inclusive.*

Years.	Pounds export'd	Pounds consumed or remaining on hand in Great Britain.	Pounds consumed or remaining on hand in other countries of Europe.
1772	97,799,263	97,791,805	7,458
1773	100,472,007	3,695,564	96,776,443
1774	97,397,252	18,698,337	78,676,915
1775	101,828,617	27,623,451	74,205,166
Tot.	397,497,139	147,809,157	249,665,982

Total exportation for the four years, 397,497,-139 lbs., or an annual average of 99,374,785 lbs. This brings up to the period of the Revolution. The following will exhibit the exportation of the article during that period.

Tot.	86,649,533	43,943,349	42,705,984

Total exportation for the 7 years, 86,649,533 lbs. or an annual average of 12,378,504 lbs. Of the total 7 years' exportation, 33,974,949 lbs. were captured by the British during the war.

The following table exhibits the exports of tobacco from the United States, for the years 1787, 1788, 1789, immediately preceding the adoption of the present constitution.

Statement showing the quantity of tobacco exported from the United States from 1787 *to* 1789, *inclusive.*

Years	Pounds export'd	Pounds consumed or remaining on hand in Great Britain.	Pounds consumed or remaining on hand in other countries of Europe.
1787	99,041,000	45,379,795	44,661,205
1788	88,595,000	39,600,404	48,995,186
1789	88,675,000	48,831,232	39,843,768
Tot.	267,311,000	133,811,431	133,500,159

*This year Great Britain exported to the continent nearly 26,000,000 lbs. of old stock.

†Great Britain exported this year to the continent 6,000,000 lbs. of former stock.

Statement exhibiting the number of hogsheads of tobacco exported from the United States from 1790 to 1835, inclusive, and the average price per pound, and gross value from 1802 to 1835, inclusive. Also the number of pounds of manufactured tobacco and snuff exported from 1791 to 1835, inclusive, and gross value from 1817 to 1835, inclusive.

It may be proper to remark, that the weight of a hogshead of tobacco is much greater now than formerly. Originally, tobacco being less compactly pressed, the hogsheads averaged only 600 lbs., but they gradually increased, and in 1770, reached 1,000 lbs. average. At this time Kentucky averages about 1,300 lbs. per hogshead, and the average of all kinds (Kentucky, Virginia, Maryland, and Ohio) we have estimated at 1200 lbs. per hogshead, which we believe to be very nearly right. The annual average exportation for the last 21 years, from 1815 to 1835, inclusive, is within a fraction of 82,760 hogsheads. Taking our estimate of 1,200 lbs. per hogshead to be the true weight, we shall thus have 99,313,000 lbs. as the annual average for the last twenty-one years; and we have seen that the annual average exportation for the four years ending in and including 1775, was 99,374,785 lbs., which establishes the remarkable fact, that the exportation of leaf tobacco has remained stationary for a period of 60 years.

On a careful examination of the foregoing statements, it appears, that when our exports of leaf tobacco, for two or three successive years, much exceed one hundred millions of pounds; for some succeeding years they are proportionably reduced below that standard. It is also evident that the

*French revolution. †Berlin and Milan Decrees. ‡Embargo. § Rambouillet Decree ‖War with Great Britain ¶ Peace.

revolutionary war gave a check to the exportation of leaf tobacco from which it has never recovered; for until that period, as may be seen by reference to the preceding statements, the annual average exportation increased regularly and steadily. It was 37,780,000 lbs. greater for the years 1763 to 1770, than for the years 1744 to 1746; and for the years 1772 to 1775, it was 31,594,785 lbs. more than the annual average for the years 1763 to 1770. In other words, for the 31 years immediately preceding the revolution, our exports of leaf tobacco annually increased very nearly 2,328,000 lbs., and for the 60 years since that period, it has remained stationary, except when interrupted by wars or other commercial embarrassments. The reason is apparent. Before the revolution, all Europe depended on us for supplies of the article; but, being cut off from the supplies, by the war, Europeans turned their attention to growing it for themselves, and have continued to cultivate it all over the continent.

It will be observed that the exportation of manufactured tobacco and snuff has increased more than forty-four fold since 1791, and more than three fold since 1817; but the gross *value* has not proportionably increased, at least since 1817.

From a review of the subject, as above detailed, it will be perceived, that, if it were in our power to furnish a precise statement of the exports of each description of tobacco, and the countries to which it was exported, (although very desirable on many accounts,) it would not furnish satisfactory evidence that the consumption of tobacco generally, or of any particular description, had increased or diminished in Europe, without knowing *what they grow*. as well as *what we export*. We have devoted much labor and attention to this part of the subject; but, although we can learn generally that the production of it in Europe keeps pace with the increased consumption, yet our researches have not enabled us to lay before you any useful statement, either as to the quantity or the qualities grown, except for three years in France, as follows:—

Statement showing the quantity of Tobacco grown in France for the years 1818—1820.

Years.	Kilogrammes.	Pounds.	No. of hhds., estimated at 1,200 lbs. per hhd.
1818	7,418,000	18,545,000	15,454
1819	10,360,000	25,900,000	21,583
1820	13,155,000	32,887,500	27,406

This shows an increased production of nearly double in the three years.

It will strike you with surprise, as it did us, that the consumption of tobacco has increased so much in our own country, as to carry off the very large surplus grown beyond the foreign demand. Formerly, when all the tobacco was grown in Virginia and Maryland, we exported as much as we do now; and now, in addition to those states, which produce nearly, or quite as much as they did then, Ohio, Kentucky and Tennessee, together with Connecticut, Pennsylvania, Indiana and Missouri, produce as much more. We must, therefore, consume more than the quantity repuired for exportation.

Remarks.—If the preceding statements may be relied on as correct, it appears that there has been a very surprising increase of the use of tobacco in this country, and that the annual consumption now amounts to upwards of 100,000,000 lbs.:—giving about 7 lbs. to every man, woman, and child. The sum annually paid by the consumers of this quantity of tobacco in its manufactured state, has been computed by a writer in "The Portsmouth Journal," at $20,000,000.

The following passage is extracted from Dr. Mussey's "Essay on the Influence of Tobacco on Life and Health."—"Eighty thousand dollars' worth of cigars, it was estimated, were consumed in the city of New York in 1810; at that rate, the present annual consumption would amount to more than $200,000. The statement of Dr. Abbot, in his 'Letters from Cuba,' in 1828, is that the consumption of tobacco in that island is immense. The Rev. Mr. Ingersoll, who passed the winter of 1832-3, in Havanna, expresses his belief that this is not an overstatement. He says, 'call the population 120,000; say half are smokers; this, at a bit (i. e. 12½ cents) a day, would make between $7,000 and $8,000. But this is too low an estimate, since not men only, but women and children smoke, and many at a large expense.' He says, that 'the free negro of Cuba appropriates a bit (i. e. 12½ cents) of his daily wages, to increase the cloud of smoke that rises from the city and country.' This, in 30 years, would amount to $7,058 72, a respectable estate for a negro, or even for a white man.

"The Rev. O. Fowler, from considerable attention to the statistics of tobacco consumption in the United States, estimates the annual cost at $10,000,000; time lost by the use of it, at $12,000,000; pauper tax which it occasions, at $3,000,000.

"This estimate, I believe to be considerably below the truth. It has been estimated, that the consumption of tobacco in this country is *eight times* as great as in France, and *three times* as great as in England, in proportion to the population."

According to an estimate given by the editor of the "New York Commercial Advertiser," in a late number of that journal, the cost of the tobacco smoked in the city of New York, is much greater than is stated by Dr. Mussey; but his estimate will probably be thought, by most readers, a great exaggeration. According to the "Commercial Advertiser," 100,000 persons in the city, (about one-third of the whole population,) are supposed to be smokers; and the average cost to each smoker is computed to be ten cents a day—total daily cost, $10,000; and the annual cost, $3,650,000. The annual cost of bread for the inhabitants of the city, allowing thirteen ounces of bread for each person, and computing flour at ten dollars per barrel would amount to $3,493,050. "Thus a little attention to the subject discloses the painful and disgusting fact that in the clear-headed, sharp-sighted, money-making city of New York, the inhabitants pay more for tobacco than they do for bread."

Statement showing the quantity and value of tobacco exported from the United States, from 1832 to 1835, inclusive.

For the Farmers' Register.

DEEP PLOUGHING, &c.

The Athenian orator, to whom your Frederic correspondent refers, who esteemed action the first canon in the art of eloquence, had reference to the taste and genius of his own times; such would not have been the answer of the late William Pitt, the prince of orators, in the age in which he lived. Your correspondent considers deep ploughing the first rule in successful agriculture: if his theory had been confined to the Valley of Virginia, I should not feel disposed to question its accuracy. Opinions founded on practical experience are entitled to great respect; but the circumstances upon which they are formed are fair subjects of investigation. I spent some time last summer in that part of Virginia, and I did not remark extraordinary diligence in improvement by lime or putrescent manures, nor did I esteem their agriculture of the highest order; but the fine crops of Indian corn and oats afforded full evidence of the richness of the soil. The cause is now disclosed in the substratum containing a portion of carbonate of lime; and improvements made in Maryland and lower Virginia at large cost, are accomplished in that fortunate valley, (for fortunate I must call it,) by the ordinary operations of cultivation. This property in the soil must give great value to the lands, and fully justifies deep ploughing.

Successful, diligent farmers, who have kept their lands up to a state of moderate product, and have improved their fortunes by thrift and care, not unfrequently speak lightly of knowledge derived from books, and, by way of reproach, call it "book farming;" and they derive support from the fact, that good theoretical writers sometimes fail greatly in their practical illustrations. I do not think it can be justly denied, that books on agriculture have contributed greatly to its improvement. By periodicals the approved experience of one region is communicated to another: I am a debtor to the Farmers' Register, and to the Cultivator; but I have seen some mischief done by confident theorists acting upon limited experience.

About thirty years ago, a farmer of this state published a tract on agriculture. Like your Frederic correspondent, he insisted that deep ploughing was suitable to all soils. He supported his theory by facts, and some plausible reasons: among others, as I recollect, that the old exhausted surface might be turned down to recover, and a fresh soil brought up for production. The scheme was generally condemned by the old and experienced farmers, but found favour with the young and confiding, and the price paid for their credulity was diminished crops and impoverished lands. The late Col. E. Floyd, of Talbot, who had then recently come into possession of his estate, and was full of enterprise, was greatly taken with the plan, and experimented to the full extent of the theory. Many years afterwards, I asked him the result of his deep ploughing: he said it proved a most injurious business, and the lands he had so treated were greatly injured. I do not think your correspondent derives support by his reference to England and Belgium; the extent of marling in those countries has rarely been attained in ours in crop cultivation. By lime, ashes, and other suitable manures, they there make a soil; in ours, we only seek to improve. If one cubic foot of suitable manure be added to three or four cubic feet of soil, it is no great matter whether the soil be sand or clay. In this we are instructed by our garden cultivators; and when the facilities of labor and the prospects of profit offer the same inducements, perhaps we shall plough our lands as deep as they do theirs in the Valley of Virginia.

Successful agriculture has of late become a matter of national consideration; whilst schemers and projectors, under color of increasing the national wealth, have received largely assistance from the general and state governments, no fostering ray has been shed on agriculture. Without any support but what it has derived from its own energies, it has been often embarrassed by the wild and extravagant schemes of the commercial and manufacturing community. The failure of the grain crop for the two last years, and the large European importations, have demonstrated that the present production, in a favorable year, is but little more than sufficient to supply domestic consumption; and when the crop is diminished by an unfavorable season, we must look to foreign countries for supplies. In the event of a war this dependence would be exceedingly precarious. Under the administration of the younger Pitt, in a year of scarcity in England, large quantities of rice were imported from the East Indies, and our old enemy, George the Third, ate potato bread, not as a punishment for his sins, but as a good example to his subjects. The "American system" (falsely so called) was adopted under color of making our country in all things independent of foreign nations; and surely, if the manufactures of cotton, wool, iron, and copper, were entitled to a high protective tariff, bread, the staff of life, demands some consideration. I would not ask from congress a protective tariff; because I think the people of the country have a just claim to articles of necessary consumption at the cheapest rate, and because I think a power imparted to the general government for one distinct, separate object, cannot be lawfully exercised for another; but I do think that a sound and enlightened policy dictates that each state should essay the discovery of its own agricultural resources and capacities. It is little more than thirty years since marl was first discovered in Talbot county; it was then thought peculiar to that region; accident, more than enterprise, has disclosed it in many parts of the Eastern Shore. A geological survey and examination of our state by skilful and faithful agents, I have no doubt, would lead to many important discoveries. I should be much better pleased to see a company of men engaged in this work, at the cost of the state, than a corps of civil engineers surveying railroads, on the borders of our navigable rivers.

In most of the schemes of internal improvement there are two classes of adventurers—a large one who pay their money, and who look for profit in the success of the project, and a small band of choice, adroit spirits, to whom the success or failure of the work is a matter of secondary importance. They count on profit in the progress of the work, in salaries, contracts, and speculating on the fluctuating of the stocks. They fully understand the signs of the times, and in prospect of a sinking concern, sell out, clear themselves, and leave the poor gents at the bottom of the well, to surfeit on bitter waters, which they had represented as exceedingly sweet.

Maryland has embarked millions on the Chesapeake and Ohio canal. The notion of carrying it further than Cumberland, I believe, is now abandoned by the wildest schemers; and remuneration is promised by the company to the state, in the transportation of coal from the Alleghany mountains. Suppose coal mines should be discovered on the waters of the Chesapeake, I apprehend the fires of the Alleghany coal would soon go out. The projectors of this great scheme have started on the hypothesis that no coal is to be found in Maryland but in the Alleghany mountains, and our profound legislature has adopted it. I have never heard that there has ever been any boring for coal in Maryland, excepting by Mr. Richard Caton of Baltimore, who was led by a German to believe there was coal at the head of the Severn, in consequence of a small quantity being found on the shore, which most people thought had floated up the river from a Virginia boat. Mr. Caton is an Englishman, a native, I believe, of Liverpool, and well knows what some of our wise men may hereafter discover, that coal is not confined to the mountain regions. There are many coal-mines in England and Ireland at no great distance from the sea. A remarkable one, at Baristones, was for many years worked with profit under the ocean. The Richmond mines are at no great distance from the tide, and coal is found in the champaign regions of the north. It wound, perhaps, have been a matter of prudent calculation, before Maryland had embarked her fortunes so deeply in the Chesapeake and Ohio canal company, to have ascertained whether coal could not be found in more accessible parts of her territory. Americans are said, by some traveller, to be a people of very ready impulse. They seize a scheme with the same avidity that old Mr. Shandy did a theory, and often run it to the same excess, of which full evidence may be found in the first annual report of the directors of the Eastern Shore railroad company, to which I invite the attention of all persons who desire a short road to Mexico.

I find I have sadly digressed from my subject: I will conclude with a very few words to the Frederic farmer. I entirely concur with him in his preference of horses to mules and oxen, as beasts of the plough. Perhaps the Conestoga is to be preferred in the Valley of Virginia; but in our hard loamy lands, where there is no stone, a pair of fine-blooded horses will plough more in three days, than a pair of Conestoga in four. His objection to the blooded horse is one of my grounds of preference: I like to see him play and gambol, even at the risk of his neck; and I prefer him to the Conestoga, as much as I do a light-hearted, mercurial Virginia yeoman (who, after the labors of the day, sports with his fellows, and indulges his stray joke, at the risk of a broken head,) to a dull, heavy Dutchman, who eats his supper, smokes his pipe, and goes to sleep.

AN EASTERN SHORE FARMER.

Queenstown, Md. May, 1838.

From (Loudon's) London Gardeners' Magazine.

JAUFFRET'S NEW MANURE.

We have in a preceding page (p. 111.*) directed attention to Kimberley's manure, said to be a most extraordinary and valuable discovery; and that of Jauffret seems to be a parallel discovery of the same kind in France. M. Jauffret, it appears from '*l'Ami des Champs*' for December, 1837, died in November last. He was born at Aix, in the neighborhood of Provence, and succeeded to a considerable landed estate there in 1798. In its cultivation, finding a great deficiency of manure, he tried innumerable schemes to increase it, till at last he hit upon a certain liquid, the composition of which remains a secret, except to those who have purchased the patent right; and which, poured upon any description of soil, mixed with organic matter, produces fermentation, and rapid decomposition. The ley *(lessive)* which is poured over the materials to be converted into manure is said to consist of various ingredients, but not to be expensive; two large heaps of materials to be converted into manure not requiring more than may be purchased for about 3s. This manure is said to have been tried in England by H. Handley, Esq., M. P., and found effective; but by others, it is represented as an imposition on the public. We have applied to sources in France which will enable us, we trust, to state something positive respecting it in our next number. In the mean time, our readers may refer to a pamphlet on the subject, of which we have elsewhere given a title. That pamphlet, however, does not give the slightest hint as to the ingredients of the ley.—*Cond.*

TREATISE ON BONE MANURE,

By Henry Colman, Commissioner for the Agricultural Survey of Massachusetts.

Bones, it is well ascertained, contain in an abundant form the food of plants. They are made up of a large amount of animal substance mixed with earthy and saline matter; and they abound in what chemists call the phosphate of lime, a substance found in some measure in all plants, and a powerful means and instrument of vegetable growth.

Bones have been used as a manure for many years in England. Used in an unbroken state, they were slow in becoming decomposed; and their effects were not very observable. The next attempt was to reduce them by burning; but besides the expense and trouble of doing this, much of the valuable matter contained in them escaped by the operation. Afterwards, mills were invented for crushing or grinding them; and since that time they have been experimented upon in various soils; and are now sought after by intelligent farmers abroad with the greatest avidity. There is no reason why they should not be used to as great advantage among us.

Bones constitute a very efficient manure; a portable manure; and a comparatively cheap manure. Stable manure in Boston and its vicinity costs the farmer in its first purchase, its transportation, and its preparation for the land, not far from five dollars a cord. His land may be manured with bone manure, with equal advantage and for a third of the expense of stable manure; and its actual improvement of the soil will be more permanent.

In England this manure has been principally used for turnips. This is the crop which on their land commonly precedes wheat. The effect on their turnip crop is very great; causing lands to produce a crop, which had been comparatively barren; forwarding the crop several days in advance of that manured with stable manure; and greatly increasing the product. The effects have been most beneficial upon all the succeeding crops of grain and grass. Few decisive experiments have been made as yet in this country; but in one case the last season, where applied to ruta baga growing side by side with a crop manured by stable manure. 25 bushels of bones produced a much better crop than a heavy dressing of barn dung.

They have been used with signal advantage spread upon grass land; the feed being greatly improved, and the return from the stock fed upon it, in milk and butter through the season, very much increased.

Their effects upon the cultivation of wheat, in Great Britain, have been thus stated after careful observation, compared with best stable manure.

"In respect to the quality of the grain, as 7 to 5.
In respect to the quantity, as 5 to 4.
In respect to the durability of its effects on the soil, as 3 to 2."

In these cases, likewise, are to be taken into consideration the difference in the cost of the two applications; the lightness of transportation of bone manure; and the ease of applying it to the soil.

Of its application to Indian corn no experiments have come within my knowledge; but its advantages cannot be questioned.

As to the form in which it is to be applied to the land, it has been tried in the form of broken dust; of pieces crushed to the average length of half an inch; and of larger pieces. If to be spread broad-cast upon grass land, it should be fine; and in all cases the more finely it is reduced the more immediate are its effects. In long pieces their application is not convenient nor efficient. In the mill at Roxbury, near Boston, they are crushed in small pieces, and at the same time in the process much comes out in the form of fine dust. This is undoubtedly the best form in which they can be furnished; the fine dust supplies the vegetable pabulum for immediate use; and the pieces being longer and gradual in their decomposition effect a permanent improvement of the soil. To the turnip crop they are applied in the drill with the seed; and in their application to Indian corn it might be advisable to deposite them in the hill.

They are sometimes applied singly or mixed with dung or mould. To be thus mixed is deemed the best mode of applying them, and in this case the dung should be decomposed and fine. A compost is formed of bone dust and barn-yard scrapings and muck in the following proportions:

From 50 bushels of bone	to 4 or 5 of dung.		
" 20	do.	to 4	do.
" 12	do.	to 8	do.

The proportions, however, must be matter of judgment and experiment with the cultivator.

It is deemed important, in the next place, that the bones should have acquired a degree of heat by being laid in a heap before application to the soil. They will soon ferment laid in a heap and mixed with earth or dung are in a condition to be used. It is deemed well if this preparation of them can be made a month before they are to be applied.

Of the quantity to be applied no certain rule can be given. From 16 to 80 and 100 bushels have been applied: 25 bushels of fine bone dust, or 40 bushels of crushed bones, pieces and dust together, are considered proper proportions for an acre. Persons have found that a larger application than this has not been attended with corresponding advantages: indeed that 25 bushels have been as efficient as 80. As it respects the permanent improvement of the land there is no doubt that the larger quantity would be in proportion efficient; but as to immediate effects no advantage is to be expected from an excessive application; as a small application will probably furnish all of that kind of food or stimulant, which the plant or a single crop will take up. Eight bushels of bone dust mixed with eight bushels of coal ashes, are represented in one experiment as efficient as the whole amount of bone dust. This was, however, only a single experiment; and the permanence of the effects had not been tested. I mention this mode, not so much from confidence in its success as in the hopes of producing experiments, which may prove instructive and useful.

Of the kind of soil to which bone manure is best suited, some matters are well determined. On wet and heavy soils it will not answer. On clayey soils it is stated to have proved positively injurious. On light, dry and sandy soils it has proved most efficacious. It is indispensable to obtaining their benefits, that the land should be dry. Lands deficient in lime are much more benefited by its use than lands abounding in lime. This was to be expected, as a combination of lime forms a considerable part of their substance. On peat soils, when thoroughly drained, its efficacy is very great; and, mixed with sandy mould, perhaps no application could be better for peat soils, when laid entirely dry.

The bone dust, which is to be obtained, is that from bones which have passed through the soap-boiler's hands. This deprives them undoubtedly of some portion of their gelatinous or oily properties, and renders them less valuable than if they could be broken and applied in an uncooked state; but the effect of this operation is not like that of calcining to deprive them of *all* the soft and oily matter; a great deal remains, and experiment has proved that their efficiency is diminished in a much less degree than would be supposed.

This is the best and most authentic information that I have been able to collect on the subject. My own experiments with them have been on a small scale; but accidental circumstances prevented my giving them a fair test. I have great confidence in their utility; and their portable character must strongly recommend them. They may be sent by railroad and water conveyances into the interior in many cases at almost as small an expense as the manure in some places can be carried from the barn into the fields. If they fulfil what they promise, the market gardeners in the neighborhood of the city must find them invaluable.

From what has been here stated we may draw these conclusions:

1. Bones constitute a most valuable manure.

2. The soils to which they are most usefully applied are sandy and light soils; and the land must be dry. On heavy loams and clays they are not useful. To peat lands completely drained they may be applied with advantage.

3. They may be sown broadcast; or they may be placed in the hill or drill. In either case they are not to be buried deep.

4. They are the best applied mixed with mould, or finely rotted barn-yard manure at the rate of six bushels of bone manure to one load of dung.

5. They may be applied to soils at the rate of twenty bushels of bone dust or forty bushels of crushed bones to an acre.

6. For immediate effect bone dust is to be preferred. For permanent improvement bones which are merely crushed into small pieces. At the Roxborough mill the prepared bone contains much fine powder mixed with the crushed bone.

7. Before they are applied they should undergo a degree of fermentation.

8. They may be applied to grass and to pasture lands with great benefit.

It is hoped that the farmers who apply them will carefully observe their operation and effects; and communicate the results to the Agricultural Commissioner of the state.

Their effects, in general, have been much superior to that of stable manure. This has not always proved so; but their lightness of carriage, ease of application, and cheapness are very strong circumstances in their favor. Another circumstance most strongly in their favor, is, that applied in great or small quantities, they carry no weeds into the fields. This is a most valuable quality.

Boston, March 26, 1838.

From the British Farmers' Magazine.

ON THE CULTIVATION OF SMALL FARMS.

Review of an "Essay on the Improvement to be made in the Cultivation of small Farms. By William Blacker, Esq. Dublin: Curry & Co. London: Groombridge."

That this little work should have gone through five editions in so short a time, is pretty good proof that the doctrine that would sweep the small farmers and cotters from the land, is being successfully combatted. The economists may talk as they like, but poor Goldsmith was right:

"Ill fares the land, to hastening ills a prey,
Where wealth accumulates and men decay;
Princes and lords may flourish or may fade;
A breath can make them, as a breath has made:
But a bold peasantry, their country's pride,
When once destroyed, can never be supplied."

Mr. Blacker is determined they shall not be destroyed. He has a better method of curing the poverty of the "peasantry," if the term must be applied to them, than by sweeping them away into workhouses and cotton factories. Their poverty, he knows, has been brought on, generally speaking, by no fault of their own; and that independent of that fact, the destruction of them would be a deadly affliction to the country.

Mr. Blacker's remedy for the poverty of the "peasantry," is *proper encouragement*:—

"I consider myself most fortunate that I am not obliged to act, at present, upon the system above alluded to," [the economist sweeping-away system,] "and that my employers, however they may feel resolved not to continue on their estates persons of careless and indolent habits, are nevertheless determined to assist and encourage all those of an opposite character; and impressed with this kind feeling, are anxious I should make trial whether any thing can be done to reclaim the one and to stimulate the other, and if possible, to put both upon some better plan of supporting themselves and their families, than they at present appear to be acquainted with.

"The only way in my mind to accomplish this is, by introducing such a system of agriculture as would bring the entire of the small farmers' holdings into a productive state, in place of allowing nearly half their farms to remain nominally in grazing, but in reality producing nothing."

He then explains what the system of agriculture he would introduce is. We must here state that Mr. Blacker appears to address himself to the tenants on an estate under his management:

"By referring to the experience of all good farmers in all countries, and under all circumstances, it is ascertained beyond dispute, that by the practice of sowing green crops, such as clover and rye-grass, winter and spring vetches, turnips, mangel wurzel, &c., the same ground which in poor pasture would scarcely feed one cow in summer, would, under the crops mentioned, feed three, or perhaps four the whole year round—by keeping the cattle in the house, and bringing the food there to them; and the manure produced by one of these cows so fed, and well bedded with the straw saved by the supply of better food, would be more than equal to that produced by three cows pastured in summer and fed in winter upon dry straw or hay, and badly littered.

"Here then are two assertions well worthy your serious attention—first, that three cows may be provided with food in the house all the year, from the same quantity of ground which will scarcely feed one under pasture for the summer; and secondly, that one cow so fed in the house, will give as much manure as three fed in the field. I call these important assertions, for if they are really founded in fact, then any of you who may now be only able to keep one cow, would, by changing his plan, be able to keep three, and each one of these producing as much manure as three fed in the way you have hitherto been accustomed to adopt—the result must be, that you would have nine times as much manure by the new method as you have hitherto had by the old.

"One acre of good clover and rye-grass, one rood of vetches, and three roods of turnips, (making up in all two acres, which are now allotted for grazing one cow in summer,) taking a stolen crop of rape after the vetches, will afford ample provision for three cows the year round. For you all know that an acre of good clover will house-feed three cows from the middle of May to the middle of October; and with the help of a rood of vetches, you will be able to save half the first cutting for hay to use during the winter. Then when the first frosts about the middle of October may have stripped the clover of its leaves, the early sown rape, which ought to be put in ridge by ridge as the vetches are cut, and the land well manured, (if the seed has been sown by the middle of July,) will be ready to cut and feed the cattle until the turnips are ripe. Here then you have plainly provision secured until towards the middle of November; and we have to calculate what remains to feed the cattle until the middle of the May following. For this purpose there is a rood of turnips for each cow. Now, an acre of the white globe and yellow Aberdeen turnip, ought to produce from thirty-five to forty tons per acre; but supposing one-half to be of the Swedish kind, let us calculate only on twenty-eight tons to the acre, which is not more than an average produce, even if they were all Swedish, and see what that calculation will yield per day for one hundred and ninety days, which is rather more than the six months. If an acre yields twenty-eight tons, a rood will yield seven tons, which being brought into pounds, will amount to fifteen thousand six hundred and eighty pounds; and this divided by one hundred and ninety days, will leave eighty-three pounds of turnips for each cow every day, which, with a small portion of the hay and straw you are possessed of, is a very sufficient allowance for a common-sized milch cow; and over and above all this, you have the second growth of the rood of rape coming forward in March and April, which would feed all the three cows much longer than would be necessary to meet the coming clover crop, even in the latest season.

"I think, therefore, I am warranted in considering my first assertion proved; namely, that the ground generally allotted to feed one cow, will in reality supply food for three—and have now only to offer some calculations as to the accumulation of manure; which I hope will be considered equally conclusive. During the summer months, your cow, which is only in the house at milking time, (and perhaps not even then, for the practice is sometimes to milk her in the field,) can afford little or no addition to the manure heap, being upon the grass both day and night; and even in winter and spring, whilst there is any open weather, they are always to be seen ranging over the fields in search of food, so that I think you cannot but admit (upon a calculation for the entire year round,) the animal is not in the house more than eight hours out of the twenty-four, and it is only the manure made during this period, which can be reckoned upon; therefore, upon this supposition, (which I think is sufficiently correct to show the strength of my argument,) if there is any truth in arithmetic, one cow fed as I calculated on, in the house for the entire twenty-four hours, will yield as much manure as three cows that are only kept in the house for eight hours—the quality of the food being supposed the same in both cases; and this would manifestly prove my assertion, that one cow fed within, would give as much manure as three fed without; and therefore when three can be kept in the one way, as I have already shown, for one kept in the other, it is as clear as three times three make nine, that the result of the calculation will be just as I have stated —namely, that the farmer will obtain by the change of system, nine times as much manure in the one case as he would have had in the other. Now, if after all that has been said, (which seems to me, at least, quite convincing,) any of you should be so astonished by the quantity of manure thus proved to be gained, as still to have some misgivings on the subject, and be inclined to think that matters would not turn out so favorable in practice as I have shown in theory, I would wish any such person to consider one very material point which I have not yet touched upon—for in the foregoing the argument is founded entirely on the time the animals are kept within, viz.—it is stated that one cow kept within for twenty-four hours, will give as much manure as three cows which are only kept in for eight hours, the food being assumed to be the same in both cases; but it is quite evident, that if the cow kept within should be fed with turnips, and bedded with the straw which the others are fed upon, leaving them little or no bedding whatever, that the calculations must turn decicedly in favor of the animal which is well fed and bedded, both as regards the quantity and quality of manure—so that it appears the estimate I have made is decidedly under the mark."

Mr. Blacker, after this, enters into minute details of the proper methods of cropping and general management. We cannot in fairness offer our readers even an abridgment of them. They are most judicious, and perfectly practicable to the utterest blunderhead that ever handled a spade. Though addressed to small farmers, not a few "big" ones would profit by attending to them.

But some of our readers will be apt to remark, that though Mr. Blacker's system is so good and perfect, the poverty of the persons who are recommended to act on it, will prevent them from doing so. This certainly seems a serious difficulty. Mr. Blacker, however, shows there is not so much difficulty as seems.

"It is seldom," he observes, "that any one deserving the appellation of even a small farmer, is so very low in the world as not to have a cow of some sort; and the more common case is, that he is possessed of one at least of those useful animals. Let us suppose him then, to have four acres of land and one cow, and that two acres are in grazing, or put out to rest, as it is termed; and of the remainder, half an acre is intended for potatoes, half an acre for first crop of oats on last year's potato ground, half an acre of second crop oats, and the remaining half acre third crop oats; which, altogether, make up the four acres; and, with a small garden, may not be considered to be an unfair representation of the general circumstances of the poorer class of small farmers. Now, if an industrious man, reduced to such a situation by bad health, or any other calamity, without capital, and without friends, was to ask me how he, as a small farmer, might contrive to extricate himself from his difficulties and retrieve his affairs—(and this is a question which, above all others, most vitally concerns the poor of Ireland)—I should answer by saying, if a small farmer means to live by his land, his first object ought to be to make every inch of that land as productive as its nature will admit of; and this can only be accomplished (as I have stated in the commencement,) by having plenty of manure, and pursuing such a rotation of crops as shall prevent the ground from being ever exhausted. Various methods may be taken by him to arrive at this, according to his particular resources and the circumstances of his farm: but, under any state of things, he must keep in mind the fixed maxims of farming already enumerated. By reference to these, he will, in the first place see, that wherever he intends to put on his manure, the land should previously be effectually drained; and likewise, that the weeds should, as far as possible, be eradicated before putting in his crop. If these directions are not attended to, a cold wet subsoil will destroy more than half the strength of the manure, and half the remainder will perhaps go to nourish the weeds, in place of the crop he intended it for. The next thing he will see pointed out is, to provide for the increase of his manure, by preparing the means of feeding his cow in the house, and to refresh his land by a change of crop. It is from want of attention to these points, the returns from his farm have been heretofore so much reduced, that he has been kept struggling in poverty, when, with less labor and more skill, he might have been living comfortably. But as an example will make every thing more intelligible, I should be inclined to recommend him, as one mode of carrying the rules laid down into practice, (draining and clearing his land being always attended to in the first instance,) to sow clover and grass-seed with his first grain crop, as a provision for house-feeding his cow the following year; and he must begin early and put in kail or cabbage into his potato ridges, and sow a succession of vetches on the stubble of his last year's potato-land oats, to serve as feeding for the present. If there should be any overplus after feeding his cow, and that he should not be able to buy pigs to consume it, he may let such part stand for seed, the produce of which will generally be more valuable than any second crop of oats, and the straw from it will be found much superior to oat straw, as fodder, and contribute to the support of his cow in winter. He will farther observe, by the fourth rule, that the manure for his green crops, such as potatoes, turnips, &c. should be put out upon that part which has been exhausted by grain, therefore let it be given to the stubble of last year's second and third crop of oats; and by attending to the fifth and sixth, and seventh rules, let him take care not to have any of his land or manure wasted; and by burning the backs of old ditches desired to be levelled, he will obtain such a quantity of ashes as will enable him, with his other manure, to sow half an acre of turnips and an entire acre of potatoes, in place of the half acre, as formerly supposed. By this means, he will be able to bring in half an acre of the poorest part of the grazing, the remaining one and a half acres of which may be used for the support of his cow, until the vetches become fit for cutting, when, if he has any ashes remaining, or as far as the summer manure will cover, the grazing may be broken up and prepared for rape. Supposing these matters to have been conducted upon this plan, when the turnips become ready for use, it will be practicable for him to fatten his cow, and sell her for a price that will enable him to make up the price of two lean ones, or at least to add a heifer to his stock. One rood of turnips is calculated to fatten a cow of moderate size, that has been well fed in summer, which his would have been on the vetches; therefore he would have remaining still one rood of turnips, the curled kail, and what rape he might have got sown, to enable him to support the two cows, thus supposed to be bought, for the remainder of the year, until the clover would be fit for use, which was formerly directed to be sown.

"In considering the foregoing, I do not see any extra outlay which can be said to render this commencement impracticable, nor any reason to suppose that the person's means of paying his rent will be in a manner curtailed; on the contrary, it appears to me that, besides the additional half acre of potatoes, the vetches substituted for the second crop of oats will produce, by the superior keep of the cow, in milk and butter, and the rearing of pigs, more than double what an inferior crop of oats would be worth; and that by these articles alone, the entire rent of a four-acre farm would, in common years, be paid, leaving the profit of the remainder of the farm to go entirely to the support of the family and the increase of the stock. But if it is clear from this statement that the farmer's circumstances the first year will not be made worse, it is still more clear that the second year they must be made better; for it is plain he will then have more than double his former quantity of manure, (owing to the turnip feeding and the second cow,) which, with the ashes of his remaining old ditches, will be fully sufficient to bring into cultivation all the remainder of the grazing land lying out to rest, which will now be made to yield him a valuable crop of potatoes and turnips, and he will have the manured land of last season, amounting to one and a half acres, in place of half an acre, as formerly: besides all which, he will have as good a crop after the vetches as after his potatoes; and thus there will be no part whatever of the entire farm which will not be under profitable crop; and the clover, with what vetches he may think it necessary to sow, will supply him with the means of feeding his two cows in the house, by continuing which practice, he will have sufficient manure to keep his land constantly in good heart, and enable him to follow for the future any rotation of crops he may think proper.

"In order to make what I have said more intelligible, I put the statement into figures, viz:—

"*Supposed Case of a Four-Acre Farm.*

Field No.		A.	R.	P.
1	In potatoes (having only one cow, and not fed in the house,) he will not be able to manure more than	0	2	0
2	In oats, upon last year's potato land	0	2	0
3	In oats, being the second crop after potatoes	0	2	0
4	In oats, being the third crop after ditto	0	2	0
5, 6, 7, 8	In grazing, lying out to rest	2	0	0
	Entire Farm Acres	4	0	0

"*Proposed Crop to begin an Improved System.*

Field No.		A.	R.	P.
1	To be sowed in wheat or oats, being last season's potato ground, and laid down with clover and grass	0	2	0
2	To be sowed in vetches, after first crop of oats	0	2	0
3	To be sowed in turnips of different kinds,	0	2	0
4, 5	To be planted in potatoes, supposed	1	0	0
6, 7, 8	Best part of the grazing to remain for one cow, with vetches	1	2	0
	Acres	4	0	0

"*Second Year of Improved System.*

Field No.		A.	R.	P.
1	In clover fit for cutting	0	2	0
2	In oats, (after vetches) if a second cow has been got, one-half vetches may be necessary, unless cabbage and kale are cultivated	0	2	0
3	In barley (after turnips) laid down with clover and grass-seed	0	2	0
4	In wheat (after potatoes) supposed planted on house manure, laid down with clover	0	2	0
5	In oats (after potatoes)	0	2	0
6	In turnips, having been trenched up before the frost	0	2	0
7, 8	In potatoes	1	0	0
	Acres	4	0	0

"The ditches of Nos. 7 and 8 burned, and the produce of two cows fed in the house for most part of the year, will give the requisite manure; and on a comparison of the crops and the keep of two cows, the return appears to be fourfold the value of what it was, with the certainty of the land every year getting better.

"I think any one who will afford a few minutes' consideration to the foregoing, will be of opinion that a satisfactory answer has been given to the question proposed, and that by a simple reference to the maxims laid down, a mode of recovery has been pointed out, which cannot fail to accomplish its object, having for its foundation, principles which may be successfully applied to the circumstances of every such farm as the case supposed; and a more important case cannot well be submitted to the consideration of the friends of Ireland, in its present situation. The plan recommended has been selected as affording a clear and concise exemplification of the operation of the principles laid down, but it is not meant to be a prescribed course that every one should invariably follow, on the contrary, it may be changed and modified in a variety of ways, according to the nature of the farm, which may call for the introduction of other crops. Thus cabbage, field peas and beans, mangel wurzel, and many other things which I have not taken into account, may, in many cases, be found more desirable than those I have adopted. Where manure is scarce, kale, and thousand-headed cabbage, are particularly valuable; they will grow with great luxuriance upon the back of a new made ditch, without manure of any kind, which proves that nothing more is required to insure a crop than to turn up new earth, by deeply trenching the ground before the frost sets in. Curled kale should be sown the last week in July, or the first week in August, and planted out as early in March as any soft weather takes place; thousand-headed cabbage should be sown in March, and planted out in June or July, as soon as the plants are sufficiently grown; both will give a plentiful crop of leaves at November, and also the following spring, besides giving a large after-cutting, in the manner of rape, when shooting up to go to seed. But, in whatever way the object is accomplished, still the principle of house-feeding, and a rotation of crops, must be equally attended to.

"I am fully aware that a person whose resources enable him to buy lime or other manure, may at once succeed in making his entire farm productive, without waiting for the slower process, which, to his poorer neighbor, may be quite indispensable; but the person with such resources, although he may hold a small farm, does not fairly belong to the class of those by whom the question was supposed to be put, and the answer therefore seems properly restricted to the single object of showing all those to whom it was addressed, that they might get on by their own industry, without any outlay beyond the means they may be fairly supposed to possess; and that if they do not better their situations, it is not by reason of its being out of their power so to do: such being the case, persons so circumstanced, I trust, will not shut their eyes to what is so plainly for their advantage to see. If their farms should be somewhat larger than the case stated, it may perhaps take a little longer time to bring them round, but still the improvement will be progressive, and they will be encouraged as they proceed, by seeing that every step is not only attended with its own peculiar advantages, but likewise facilitates that which is to follow; and I therefore cannot but hope, that any among you whose cases may resemble that which has been stated, may be induced to take what has been said into their most serious consideration, and to try the effect of the proposed change in their system of cultivation, notwithstanding the obstacles which may be started by those who are too indolent to exert themselves, or so much prejudiced in favor of old habits as to think they cannot be improved."

He concludes by showing how he proceeded to improve the condition of the small farmers on Lord Gosford's estate.

"In this, I hope, I have at least so far succeeded as in some degree to weaken your attachments to old customs, and dispose you to follow such instructions as may be given to you; and in order to set aside any excuses that might be made, either on account of ignorance or inability, I have, with the concurrence of your landlords, engaged two Scotch farmers, or agriculturists, for the purpose of giving the instructions you so much require. You will find them to be practical men, who have had experience of every kind of soil, and know how each should be treated. After minutely examining your different farms, they will point out to you how they are to be drained, cleaned, and prepared for the growth of green crops, so as to introduce the plan of house-feeding and accumulating of manure, which has been already insisted on. Thus your want of skill in the management of your land will at once be remedied; and then, to provide you with manure, (the want of which, at present, I am aware would incapacitate you from cultivating the crops recommended,) your landlords have kindly consented to lend such of you as may require assistance, as much lime as will be sufficient to insure you as many potatoes as you may require for your families; on condition that the house manure you may be possessed of shall go to the other crops which the agriculturist may point out. Thus nothing will be wanting to the perfect cultivation of your farms, but your own industry and that of your families; for the above-mentioned assistance will be continued to all such as show themselves deserving of it, until they are brought into a situation no longer to require it. My employers, therefore, I repeat, having gone to such expense and trouble to better the condition of the small farmers on their estates, and the benefit to be derived by following some better plan of cultivation being so evident to the commonest understanding, no one who, by his own want of industry, fails to take advantage of the assistance offered, can have just grounds of complaint, if the land, which he refuses to cultivate, is taken from him, and given to some of his more industrious neighbors, which will most assuredly be the case, when a fair time for making the experiment has been allowed."

We earnestly recommend the Essay of Mr. Blacker to all those who are anxious to preserve the small farmers and cotters, "the bold peasantry," who should be "their country's pride," on the land. Its principles are as applicable in England as in Ireland. D.

ROUTE OF THE MICHIGAN AND ILLINOIS CANAL.

[The following is the most particular account of what will be (when completed) the most grand and remarkable public work in the world. The opening of navigation from the great northern lakes to the Illinois river, and thus connecting the Atlantic, by way of the Hudson and the St. Lawrence, with the Mississippi and the Gulf of Mexico, would of itself be a very great work, and of incalculable value, when the great and rich north-western region shall have been brought generally under cultivation. But the economical effects of this work, great as they will be, are far less striking to the imagination, then the manner in which the navigation will be made; which is by giving to the water of Lake Michigan a new and opposite direction, down the Mississippi. According to the statements given below, of the levels of the waters, and the intervening land, it is practicable, by increasing the depth of the artificial canal, to draw off any quantity of the water of the great lakes Michigan, Superior and Huron, down the channel of the Mississippi; and even to make this new outlet, the principal one of these great sources of the St. Lawrence; if there were any sufficient object for directing these waters to the Gulf of Mexico instead of the Gulf of St. Lawrence. The world perhaps does not afford so magnificent a subject, for the art and labor of man to change and control the appearance and the action of nature. One of the ancient kings of Abyssinia made a vain effort to convey the waters of the upper Nile, by a canal, into the Red Sea, for the purpose of depriving Egypt, of that source of fertility, and even of existence. In this case, a diversion of a much greater volume of water, and to a more remote destination, will be perfectly practicable; and the power which holds the upper extremity of the canal, may at pleasure direct this enormous flood either to a northern or a southern part of the ocean, two thousand miles apart.

But the interest of these speculations extends still farther, and to another subject. It is evident, from the geological features of the country, that the great northern lakes at some early time stood so much higher than at present, that part at least of their waters actually were discharged down the valley of the Mississippi; and that the proposed new canal will but renew a passage of water which nature had at first provided. The great barrier of limestone which forms the southern boundary of Lake Michigan was less destructible than that which is still wearing away under the action of the cataract of Niagara; and by that slow but continued process the levels of the lakes have been greatly lowered.—Ed. Far. Reg.]

[Extract from the Journal of Science.]

Before dismissing this very striking appearance of the coast connected with the action of the lake, I must be permitted to express the opinion, that a careful examination of the country bordering on the Kankakee and the Des Plaines valleys, will afford evidence of the occasional overflow of the lake at ancient periods, in those directions. It is a well known fact, that the lip of the lake, near its south-western extremity, is at one place so depressed as to permit canoes to pass from the head waters of the Chicago river across to that of the Des Plaines. Nor would the circumstance cease to be an alarming one to the safety of this portion of country, except for the fact that the border to the lake is every where composed of a firm limestone. If then the waters of the lake are still capable of interlocking with those of the Des Plaines, it is clear that at a higher level of the lake, considerable descents of water upon the low country must have taken place. Traces of such incursions appear to exist on the stage road from Chicago to Ottawa, in the general direction of the swells of land on the rolling prairie, and more particularly in the width and depth of the Des Plaines valley, and the immense diluvial accumulations it contains below Juliet.

No internal improvement in the country will surpass in commercial importance the canal which is to unite the waters of Lake Michigan and Illinois river, since it will complete the navigable route from the Gulf of St. Lawrence to the Gulf of Mexico, and open a water communication, so to speak, from the Rocky mountains to the Atlantic coast. The cost of the undertaking in some degree keeps pace with its importance; for although neither the line of its extent, nor the amount of its lockage, is great, still the difficulty which grows out of obtaining an adequate supply of water for the summit division of the route, renders it the most expensive work of the kind ever projected. It is indeed a fortunate circumstance as affecting the certainty of its completion, that the means for defraying its construction are already in the possession of the state, the general government having given the alternate sections of land for five miles on each side of the canal to the state of Illinois, to be appropriated to this important undertaking.

Before speaking of the geological features of the country over which the canal passes, a brief sketch of the route it takes, and the nature of the difficulties it has to encounter, will be given, inasmuch as such a notice will serve in some degree to explain the topographical features of the region.

The canal passes up the south branch of the Chicago river a distance of four miles, thence over the level prairie in a direct line eight miles, to the valley of the Des Plaines river, down the valley of this stream, past the mouth of the Kankakee, to the banks of the Illinois, whose border it pursues for a distance of fourteen miles below Ottawa, where it enters the river. Its length is one hundred and two miles; and it is constructed with a breadth of sixty feet at the water surface, and a depth of six feet. The lockage is all downwards, and amounts to one hundred and forty-two feet.

Before adopting the present route, an attempt was made to obtain a supply of water for the summit division, from the Des Plaines, the Calumet, and the Fox rivers; but on running a level from the Des Plaines, nearly opposite the mouth of Portage lake, to the Fox river at Elgin, (thirty-five miles south of the state line,) where the surface of the stream is one hundred and fifteen feet above Lake Michigan, it was found, that the intervening ridge had an elevation of fifty or sixty feet, the cutting down of which would be too expensive to justify the expedient. The commissioners were accordingly led to adopt the magnificent plan of making Michigan the feeder to the canal. The first level thereby becomes thirty-four miles in length, with an average depth of cutting of eighteen feet, which is principally in solid rock. The depth of six feet of water has been decided on, in order to secure to the canal a constant depth of four feet during the fluctuations of tide in the lake, occasioned by high winds. A declivity is given to the bottom of the canal, of one-tenth of a foot per mile. There are two locks situated at the end of this level, having a lift of eighteen feet. Above the first of these, for the distance of three quarters of a mile, the canal has a width of one hundred and twenty feet. The estimated expense of this level is $5,871,324.

The middle division of the work extends thirty-seven miles from the head of the first lock. It has six locks, with an aggregate lockage of fifty-seven feet in the first four miles, for the whole of which distance the route is over little better than solid rock, and is consequently very expensive. Another difficult portion of this division commences about two miles below the crossing of the Du Page, and extends nearly to Dresden, below the mouth of the Kankakee. The bluffs here are from one hundred to one hundred and fifty feet high, and approach so near the river as to be washed by it, which renders it necessary to construct the towing path wholly or in part, in the river, for a distance of more than two miles; consequently, an expensive protection will be demanded to defend the work from the ice-floods of the Kankakee.

The western division has sixty-eight feet lockage, and is twenty-nine miles in length, exclusive of four miles of the Fox river feeder. From the first lock, below Ottawa, to the termination of the canal at La Salle, (on *section* fifteen,) the route lies through much wet ground, being along the bottoms of the Illinois, just under its northern bluff. As these lands are overflowed during the spring-freshets, the level of the canal requires to be considerably raised, and to be guarded by strong embankments. The construction of a canal-basin, at the termination of the canal, with an area of five and a half acres, whose bottom is to be considerably elevated above the present level of the bottom-lands, serves to render this division of the undertaking also very expensive. The cost of the entire canal, as estimated according to the report of the commissioners, is \$8,654,337; but it is admitted that the estimate is too low, it being generally believed that the work will not be brought to a state of completion under ten millions of dollars.

The geology of the chief portion of the route above described, is exceedingly simple and uniform, the great rock formation of the country being the *magnesian limestone;* at least, this is the rock from the commencement of the canal, (four miles from Chicago,) nearly to the mouth of the Kankakee. It also re-appears west of the Fox river, as will presently be pointed out, and enjoys a wide distribution probably throughout the whole of Upper Illinois and Wisconsin. A good opportunity for examining its character occurs near Chicago, where the excavations have already been commenced. It here rises quite to the surface of the prairie. It is imperfectly stratified, with an evident dip of 10° or 15° to the north-west. Its color is light grayish-white, with a frequent shade of yellow. It is compact in texture, and often slightly cellular or cavernous—a peculiarity which seems to be connected, for the most part, with the profusion of organic remains existing among its materials at the period of its formation. The following is a brief list of the fossils which fell under my observation at this locality: two species of *Orthocera*, a *Turbo* (one and a half inches in diameter) with a depressed spire; a large species of *Pectunculus? ;* a *Terebratula*, (with very prominent ribs, and but few in number;) two species of *Ammonites;* a *Caryophyllia*, and a *Favosites.** Some of the beds are wanting in fossils, and occasionally the rock puts on a shistose or slaty structure, in which case it forms a valuable flagging-stone, which is already employed to some extent in Chicago.

The same rock re-appears in the bed of the Des Plaines, twelve miles from Chicago, on the road to Juliet, as well as near the surface of the prairie at Plainfield, nine miles from Juliet, and very abundantly also at this last place. The beds at Plainfield and Juliet, however, are not rich in fossils. The rock is quite close in its structure, and where acted on by the weather, of a yellowish buff color, much resembling the lithographic stone of Sohlenhofen, in Bavaria. The quarries at Juliet afford it in very even, distinctly stratified layers, whose position is nearly horizontal, their thickness being such as to render it a very valuable building material. I noticed one variety of the rock at this place, which had been thrown out in sinking a well, the appearance of which was very analogous to that of true dolomite, (the gurhofian variety.) Its color is a grayish-white, with a tinge of green; throughout the masses were crevices and openings, whose walls were lined with transparent crystals of quartz.

The magnesian limestone continues very abundantly in the bed of the Des Plaines, below Juliet, and recurs frequently on the road across the prairie to Holderman's grove, twelve miles east of Ottawa; after which, no more rock was observed until I reached the bed of Fox river, just above the village of Ottawa. At this point, we strike upon the coal formation.

Of the existence of formations more recent than the magnesian limestone in this region, my own observation permits me to add nothing, beyond what has already been stated under the head of the lake shore near Chicago. By the kindness, however, of Mr. W. B. OGDEN, the mayor of Chicago, and Col. THORNTON, president of the board of commissioners for the canal, I am enabled to annex some additional particulars. The excavations for the canal on the wet prairie give the following superficial formations: one to two feet, black vegetable mould, and two to six feet, yellow, clayey loam, resting on blue clay. On reaching the Des Plaines, the sections give, in the first place, one foot of black mould; secondly, four feet, yellow sandy clay; thirdly, one and a half feet clean black sand, and lastly, twelve feet "vegetable formations with shells."*

The occurrence of boulders in the rolling prairie had often been mentioned to me, under the significant and original appellation bestowed upon them in this region, of "lost rocks." Their abundance, however, surpassed my expectation. They first attracted attention soon after leaving the twelve-mile house from Chicago, and appeared to form a belt between a quarter and half a mile in width, whose direction was north-west and south-east. In crossing this belt, it was uncommon to pass many rods without encountering a boulder. In general, they were rather more than half buried in the soil. They varied in diameter, from ten inches up to three feet, and belonged to the following species of rocks; granite, granitic gneiss, and trap. A few detached boulders only were noticed between this deposit and Ottawa. Soon after leaving this place, however, another band or patch of them was passed. They were here scattered over the Illinois bottoms so plentifully, as to prove objects of no inconsiderable annoyance in the road. Two miles below this locality, likewise, a number of large masses were seen. Others were occasionally met with south of this point, out upon the rolling prairie, in the direction of Vermilionville. What serves materially to heighten our interest in these boulders is, the consideration that they must have been transported over a distance of between two and three hundred miles, since the southern shore of Lake Superior is the nearest region affording rocks of a similar character, *in situ*.

* Several of these species I am persuaded are new; but I defer a particular description of them until I shall obtain an additional supply of specimens, promised me by Dr. Brainard, of Chicago.

* From the same source, I learn that the magnesian limestone beneath these deposits often abounds with vertical fissures, filled with clay, from one inch to several feet in breadth.

BADEN CORN—FOSSIL SHELL BANKS OF SOUTH CAROLINA.

To the Editor of the Farmers' Register.

Columbia, S. C., May 9th, 1838.

A writer in your last number is desirous to have it established, that the Baden, or twin corn, of Maryland, will yield 20 per cent. more than the common corn. In reply to this writer, I will state my experience of it last year in South Carolina.

I planted two acres of this corn on gray, clayey, high land in Fairfield district. The ground had been several years under cultivation, and the corn was moderately manured with compost in the hill. It was planted six feet by two apart, one stalk in a hill. It grew vigorously, and looked well until a drought overtook it in the midst of silking. It did not grow quite as tall as our common corn, (which seems to be a variety formed from the old gourd seed and Tuscarora,) yet the stalks were rather larger and more robust, and it was earlier by two or three weeks. It had put forth luxuriant shoots in abundance, from six to thirteen on every stalk; but the drought seemed to act upon it with peculiar severity, and very many of the shoots perished. When ripe, however, I found it was pretty good corn; and at the gathering, I had one acre of this, and one of the best acres of common corn measured off, that was planted about the same time, on the same kind of land, and measured in the same way; and the corn of each carefully measured for the purpose of comparison. The acre of common corn yielded twenty-four bushels, and the acre of Baden yielded thirty-one bushels and twenty-eight quarts. Here then was a product of upwards of thirty per cent. in favor of the Baden corn. Nevertheless, I should not like to trust to a crop of Baden corn on high land, unless it were naturally rich, or highly manured. A drought in silking time, seemed to be more severe upon it than upon the common corn; and although this may be accounted for in part from the fact, that the common corn was later, and did not get into silk until later in the drought, yet, nevertheless, the Baden corn puts forth such a profusion of shoots, it must necessarily require more rain to support them than a corn that bears only one or two: and if growing upon poor high lands, a drought should fall upon it at the period of silking, I should apprehend a serious failure. I think upon rich high land, retentive of moisture, and especially upon rich, moist, bottom lands, it would yield a prodigious crop. As seed has been pretty widely spread this spring from this crop of mine, we shall have an opportunity next fall for forming a more correct opinion of it.

In your remarks on the Hon. Mr. Elmore's communication, you seem not to have been apprised of the existence of the fossil shell banks of South Carolina. They have been recognised as a continuation of the shell beds of Virginia and North Carolina, from the time of the earliest records of our state. About four years ago, I analyzed a specimen of these shells from a plantation called Mount Moriah, on the Santee, and found it to contain eighty-eight per cent. of carbonate of lime. I then urged it on the proprietor and others, to make a trial of its effects upon their soils; but until the present spring, I believe, not a single trial has been attempted. These beds crop out prominently from the banks of the Santee; and there are abundant indications that they lie extensively at some depth, more or less, underneath the surface of all that belt of country quite across the state, and sometimes crop out upon the surface. Nevertheless, I have reason to believe from all the information I have been able to obtain, that the soil of that region generally contains little or no lime, and their lands are not generally productive. I learn, however, there are certain limited localities, some of which have been more than one hundred years under cultivation, that are still extremely fertile. Is it not probable that these are spots where the shells formerly cropped out upon the surface, and have been decomposed and mixed with the soil?

In conversing with some gentlemen from that section last fall, I was pleased to learn that a spirit for making experiments with these shells was springing up; so that after this year we may hope to begin to hear of some of the results. The community of a considerable part of this shell region is already wealthy; but it is probable they have under their feet a mine that will rapidly increase their wealth very many fold.

J. D.

P. S. The early character of the Baden corn renders it very suitable for replanting the general crop, as the fodder will all ripen together.

From the Cultivator.

CULTURE OF ONIONS.

The onion grows to full size in the northern states in *one* season; but in Pennsylvania and south, it requires *two* seasons to perfect its growth. There, the tops generally die the first season, when the bulb has attained the size of a filbert or walnut; these are planted out the second season, and come to maturity. * *

The cause of the difference, we believe, is to be imputed wholly to climate: the warm weather of the south impairing the elaborating organs—the leaves—and consequently checking the growth, before the bulb has time to acquire the full size. We remember seeing, in the garden of Col. McAllister, near Harrisburgh, Pa., a bed of full grown onions, which the owner seemed proud in assuring us had grown from the seed that year, and which he stated as a remarkable circumstance. We made no inquiry when they were sown, but conjecture that the seed was sown the previous autumn, a practice which, according to Loudon, is common in Portugal, and is often practised in Britain. The onion, in this case, attains its full size by the first of August, before the intense heats of summer. Although the onion is said to be a native of Spain, it probably is indigenous to the mountainous regions, for it seems adapted to the the temperature of this latitude. It withstands our winters, especially if protected by straw or litter. The onion planted for seed is often put out in autumn, or left in the ground for a second, after the first crop of seed has been gathered; it is often sown in September, and particularly the tree or bulb bearing variety. We recommend to sow in autumn, say in September or October, and at mid-winter, if the state of the ground will permit.

Onions are sown in this neighborhood from the 1st to the 25th April, on rich, well prepared ground, in drills 12 inches apart, and are afterwards thinned to a proper distance. The earlier they are sown, the sooner they come to maturity; and, well managed, are a sure and profitable crop.

The tree onion is said to come from a high latitude, where the climate being too cold for them to flower and seed, the flower becomes viviparous, and bears bulbs instead of flowers.

FACT IN NATURAL HISTORY.

We understand that the Beaver has been discovered in Surrey county, near Cabin Point, from 40 to 50 miles from this city. It was for some time believed that they were extinct in that part of the country. A correspondent says: "We saw the dams they had formed of the branches of trees thrown across, and we brought home several of the bits of wood nibbled by them for that purpose." As it is possible they may also be found in some of the adjoining counties in Virginia, we should be happy to receive communications upon the subject. —*Richmond Enquirer.*

LOSS OF SPECIES OF PLANTS.

M. De St. Hilaire states that many species of plants have been lost within the period of history. Within a few years, many species, quite common in the environs of Paris have become very rare; Scilla italica, Spartium purgans, and Pæonia corallina have entirely disappeared from the neighborhood of Orleans; and, even in our own days, the rocks of Vaucluse have been completely despoiled of the Asplenium Petrarchæ. Is it not possible, then, he adds, that many flowering plants, really phosphorescent, may have been lost in the long period which has elapsed since the days of Democritus, Pliny, and Josephus?—*L'Echo du Monde Savant.*

SILK WORMS FED UPON RICE.

In a Chinese work on the culture of the silkworm, lately translated into French by M. S. Julien, a curious process is mentioned, the correctness of which has been proved by experiment. It is said that, in China, in order to supply more nourishment to the silkworms, the mulberry leaves upon which they feed are powdered with the flour of rice. But M. Bonafons of Turin, who translated the work into Italian from the French, wishing to prove the truth of the Chinese process, powdered the mulberry leaves with the flour of rice, with wheat flour, and with other fecula; and found that these various substances, which otherwise are not eaten by the silkworms, become, in this case, excellent nourishment, and cause the worms to develope themselves rapidly. The cocoons of the silkworms fed upon rice flour are much finer and heavier than usual. The other kinds of fecula did not produce a satisfactory result; but it is to be hoped that, by experiments made among the European keepers of silkworms with different farinaceous substances some substitute may be found for the rice.—*Ibid.*

From the Louisville Advertiser.

THE GREAT WORK DONE.

The Herculean task of removing the great Red river raft, has been accomplished. A free and safe navigation for steamboats has been opened entirely through it. If we may be allowed the expression, a mighty river has been restored to its natural channel, from which it had been forced for some centuries. Many steam and keel boats have passed through the channel where the raft was, and heavily freighted. The United States steamer passed out of the head of the raft on the 29th ult., having run up from Shreveport, a distance of fifty two miles, in seven hours and fifty-two minutes. Shreveport is on the river, one hundred and fifteen miles above the original foot of the raft. This shows that the raft was one hundred and sixty-seven miles in length—much of which was covered with a rich soil and heavy timber.

From the point lately termed the head of the raft to the mouth of the Kiamecha river, a distance of six hundred miles, there is no obstruction to the navigation of Red river, and the land is as fertile as any on this continent. In addition to this it is said the tributary streams of Red river afford about eighteen hundred miles of good steamboat navigation, the advantages of which depended on the removal of the raft. When the great work was completed, there was in the country above it about twenty thousand bales of cotton, which have probably been freighted since on steamers to New Orleans. In the region of the raft, we learn the country is rapidly settling, and it is believed two hundred and fifty thousand bales of cotton will be made on lands redeemed by the removal of the raft, in 1842. The value of the improvement is really incalculable. Towns and villages are springing into existence and flourishing where there was nothing but one wide wilderness in 1834. The dense forest is disappearing and immense cotton fields are to be seen in almost every direction. The inhabitants are not squatters, but men owning from forty to two hundred slaves—planters, who will make from two to three hundred bales of cotton each in 1838.

We also learn that vast beds of iron ore have been found in the vicinity of the head of the Raft.

It would thus appear that the ingenuity, perseverance and boldness of H. M. Shreve, superintendent of the work, have added thousands of miles to the steamboat navigation of the southwest, doubled the value of some thirty or forty millions of acres of public land, given an impetus to cotton growing in that region which will accelerate the onward march of New Orleans, and opened a new and most fertile region to the enterprise of his fellow citizens. His snag boats have been found not only serviceable but indispensable machines. Without them the great undertaking could not have been accomplished for several years to come.

From the American Almanac, for 1838.

AGE AND SIZE OF TREES.

There is a great difference in the age that may be attained by different kinds of trees. Some continue to flourish through a long series of ages; nor can any definite time be assigned to them as the natural period of their existence. There are individual trees whose age, as computed by some naturalists, would carry back the commencement of their existence to a period anterior to the deluge; and though we have no very satisfactory evidence that there are any trees now existing of so great an age; yet there is no physical impossibility that such may be the fact.

The age of many kinds of trees may be ascertained, with some degree of accuracy, by felling them and counting the number of the concentric circles or rings of their stem or trunk. The age of trees is also estimated, while they are standing, by their size, appearance, and a knowledge of the laws by which their growth is regulated; and there are some old and celebrated trees, the age of which is known, with some degree of accuracy, by historical documents. There are, however, but very few of the most remarkable veterans of the forest or the field, of which the ages can be ascertained with any precision.

We can notice briefly only a few of the most remarkable trees. For further information, we would refer to the writings of Michaux and De Candolle, the volume on Timber Trees, in "The Library of Entertaining Knowledge," "The Penny Cyclopædia," and "Gentleman's Magazine," for June 1836. The facts in this paper have been derived from these sources and from other works to which reference is made.

1. "The *oaks* are among the patriarchs of Europe." In America there are no less than 29 varieties of the oak enumerated by Michaux. The white oak of the American forest is a much taller tree than the British oak; though its timber is not so hard nor so durable. "It is," says Michaux, "70 or 80 feet high, and 6 or 7 feet in diameter; but its proportions vary with the soil and climate."

The *Wallace oak*, at Ellerslie, in Scotland, 3 miles from Paisley, was a remarkable object at the beginning of the 14th century, and must be at least 700 years old. Its branches are said to have covered a Scotch acre of ground. Many cases of oaks of extreme old age are recorded, some of which have been estimated at 1,500 or 1,600 years. The largest oak known in England, was called Damory's, in Dorsetshire, and was 68 feet in circumference. It was destroyed in 1755. The largest oaks now growing in England, are two near Cranborne Lodge, Windsor; one 38, the other 36 feet round.

There has recently been published in the newspapers a notice of an oak at Ashton, England, said to be the finest in the country, which had been lately sold for 60 guineas, and was expected to be cut down when the barking season for the year (1837) should arrive. The circumference of its trunk, 6 feet above the ground, is stated at 20 feet; the length 72; the circumference at this height being 2 feet. About 30 years since it was sold for £100; but a chancery suit then arose, which saved it from the axe.

In Samagitia, Poland, 30 miles from Kowno, there was a famous oak, which was cut down in 1812. It was 38½ French feet in circumference, and 14 in diameter. "When sawed through, its age was clearly discernible, and found to be almost 600 years."—*Bib. Univ. Aug.* 1831.

Mr. Welles, in a communication in "The New England Farmer," states that in a lot in Dorchester, [Mass.,] given by Governor Stoughton, for the benefit of college education to Dorchester scholars, he measured several oaks which were from 18 to 20 feet in circumference; and in one of them he counted 200 rings, indicating as many years.

The writer of an article on "American Forest Trees," in "The North American Review," for April, 1837, says:—"The largest oak, and indeed the largest tree which we have seen in this country, is a white oak, on the estate of James Wadsworth, Esq., of Genesee, N. Y. The tree is from 24 to 27 feet in circumference at the smallest part of the trunk. Its age cannot be less than 500 years, and it must, therefore, have been a majestic tree at the time when Columbus discovered the western world. It appears to be still in a healthy and vigorous condition, and bears in its exterior no marks whatever of decay. It is by no means improbable that this tree exceeds in size many both in Europe and elsewhere, which are recorded as of greater diameter. For, in the measurement of large trees, it is of great importance to ascertain at what part of the trunk the measurement was taken. Every one must have remarked the difference between the bulk of such trees at the surface of the ground, and at a few feet above."

2. The *yew* attains a great age. The famous *Ankerwyke yew*, near Staines, in England, is older than the meeting of the English barons at Runnymede, when they compelled King John to grant Magna Charta. It is 9¼ feet in diameter. The yews at Fountain's Abbey, in Yorkshire, are estimated at more than 1,200 years old; and some at Fotheringay, in Scotland, have been computed at 2,500 or 2,600 years. One at Fortingal, in Perthshire, is said to be 56½ in circumference; one at Brabourn in Kent, nearly 20 feet in diameter; and one at Hedsor, in Bucks, 27 feet in diameter.

3. The *lime* is said to acquire a larger diameter, in a given time, than any other European tree. There is one at Friburg, in Switzerland, which was planted in 1476, on the occasion of the battle of Morat; and it now has a diameter of 13 feet and 9 inches.

A lime at Trons, in the Grisons, which was a celebrated plant in 1424, existed in 1798, when it measured 51 feet in circumference. Its age is computed by De Candolle at 583 years.

4. The *elm*, both of Europe and America, is a large tree, and has a rapid growth; but the American elm has a more majestic appearance than that of Europe. The former is represented by Michaux as much inferior to the latter for useful purposes; yet he characterizes the American elm as "the most magnificent vegetable of the temperate zone." One which grew at Morges, in Pays de Vaud, is mentioned by De Candolle, which he estimated at 335 years old; and its trunk was 17 feet 7 inches in diameter—(the foot of Pays de Vaud.) Mr. Strutt mentions an elm of

30 feet in circumference, planted in the reign of Stephen; and one near Powick Bridge, Worcestershire, is 25 feet round. The largest elm of Scotch growth, now nearly destroyed, in Teviotdale, near Roxburgh, measured, in 1796, 30 feet in girth.

The elm on Boston common is very conspicuous, both on account of its situation and size; and it is a very beautiful and well proportioned object. According to the statement of Mr. Welles, in "The New England Farmer," "it measures near the ground 23 feet, and about 3 feet above, 20 feet in circumference." Mr. Welles mentions, that "a publication states the measurement of an elm at Hatfield, Mass., as 34 feet in circumference, at 2 feet from the ground, and 24 feet 8 inches above, with a supposition that it is the largest tree in New England. But 'The Gazette' of Northampton states that there are several elms which would compete with it in that place, measuring 21, 22, and even 25 feet, and that one is said to measure 28 feet at some distance from the ground." —*N. E. Farmer*.

5. Some *cedars* on Lebanon, measured in 1660 by Maundrell and Pococke, were found to be 36½ feet in circumference; and were computed to be then 609 years old, and about 800 years old in 1787, when seen by M. Labellordière.

6. In the garden of Olives at Jerusalem, there are now existing eight *olives*, which can be proved by historical documents to have existed anterior to the taking of Jerusalum by the Turks; and consequently must be at least 800 years old.

7. "In the island of Teneriffe, there is a *dragonier*, or *dracæna draco*, which is reputed to have lived a thousand years, and is called the *great dragon*. In 1402, when the island was conquered by Bethancourt, it was as large and as hollow as it now is. Humboldt measured it in 1799, and found it to be 45 French feet in circumference a little above its root. This tree is called dragon's-blood, because there flows from its trunk during the dog-days, a liquor of a deep red, like blood, which is soon condensed, and becomes dry and brittle. It is the true dragon's blood of the shops." *Nouv. Dict. d'Hist. Nat.* This famous tree, which has been frequently visited by travellers, was destroyed by a storm in 1822.

8. The *banian* or *burr tree* (the *ficus indica)* is one of the most curious and beautiful productions of nature. Each tree is in itself a grove, being composed of numerous stems or trunks which are connected together; some of the stems being the size of a large tree. A celebrated banian, called the cubbeer burr, stands on an island in the Nerbuddah, near Baroach in Hindostan. It is said by the natives to be 3,000 years old. It is described by Milton in his "Paradise Lost;" and it is supposed by some to be the same that was visited by Nearchus, an officer of Alexander. The large trunks of this tree amount to 350, and the smaller ones exceed 3,000; and each of these is constantly sending forth branches and hanging roots to form other trunks. The circumference of the whole is nearly 2,000 feet.—*Clarke, Penny Mag.*

9. There are three celebrated *sweet-chestnuts*, on the side of Mount Etna, called *de' cento cavilli*, 180 feet in circumference at the bottom of the trunk; *di santa agatha*, 70 feet; and *della nave*, 64 feet in circumference. They must be of high antiquity; but nothing precise is known on this point; and it almost certain that the first mentioned has been, in reality, formed of five or six trunks grown together. According to Brydone and Glover, this chestnut is 204 feet in circumference.

The Tortworth chestnut belonging to Lord Ducie, in Gloucestershire, England, has been computed to be 900 years old. It measures 50 feet in circumference 5 feet from the ground; and the height of the main stem is 70 feet.

10. The *baobab* of Africa, considered by Humboldt, "the oldest organic monument of our planet," is estimated by Adanson at the extraordinary age of 5,150 years; and, if this is not an over-estimate, it must have been a tree of considerable age at the time of the deluge! The method adopted by Adanson for ascertaining the age of the baobab, was by making a deep cut in the side of the trunk and counting the concentric rings; and thereby ascertaining the proportion between the number and the part of the diameter examined and the whole diameter. But this method cannot insure an accurate computation. The enormous dimensions of its trunk bear a striking disproportion to the other parts. It is not uncommon to find a trunk not more than 12 or 15 feet from the root to the branches, with circumference of 75 to 78 feet. Humboldt mentions baobabs having a diameter of 30 feet. The size of the flowers is said to be in proportion to the size of the tree.

11. Some *cypresses* that were celebrated even in the time of the Moorish kings, existed in the palace-garden of Granada, in 1776, and were supposed to be at least 800 or 900 years old. In America, according to Michaux, the largest stocks of the cypress are 120 feet in height, and from 25 to 40 feet in circumference, above the conical base, which at the surface of the earth, is always three or four times as large as the continued diameter of the trunk. Strabo mentions a cypress in Persia, in girth as much as five men could span; and he believed it to be as much as 2,500 years old. At Atlexo there is a cypress 76 feet in circumference; and one at St. Maria del Tuli, 118 feet round. The deciduous cypress of Chapultepec in Mexico, said to be 117 feet 10 inches in circumference, the younger De Candolle considers even older than the baobab tree above noticed.

12. The *plane tree* (the *platanus orientalis* of the eastern continent, and the *platanus occidentalis* of America) commonly known in the Eastern States by the name of the *button-wood*, and in the Western States by that of the *sycamore*, is celebrated in both continents for size and majestic appearance; but the American species is said to possess a richer foliage, and afford a deeper shade than the Asiatic.

There is now growing in the valley of Bujukdere, near Constantinople, an immense oriental plane, 150 feet in circumference, with an internal cavity of 80 feet. Pliny mentions a plane tree in Lycia, which had a hollow trunk, that afforded a retreat for the night to the Roman consul Licinius Mutianus, with 18 persons of his retinue. This interior grotto was 75 feet in circumference, and the summit of the tree resembled a small forest.

"The *sycamore (platanus occidentalis)*," says Mr. Flint, in his "Geography of the Mississippi Valley," "is the king of the western forests. It flourishes alike in every part of the valley that we have seen. It is the largest tree of our woods, and rises in the most graceful forms, with vast spreading lateral branches, covered with bark of a brilliant white. A tree of this kind near Marietta, (Ohio,) measured 15½ feet in diameter. We have seen one on the Big Miami, which we thought still larger. Judge Tucker, of Missouri, cut off a section of a hollow trunk of a sycamore, and applied a roof to it, and fitted it up for a study. It was regularly cylindrical, and when fitted up with a stove and other arrangements, made an ample and convenient apartment."

A hollow trunk of an enormous sycamore was fitted up with the requisite appendages and made use of at Utica, N. Y., as a retail shop; and it was afterwards carried to the city of New York for a show. The following notice of such an object, which was exhibited in the saloon of the American Museum, and supposed the same that was used at Utica, is extracted from the New York Traveller. "A sycamore tree of most singular and extraordinary size has been brought to this city from the western part of this state. The interior is hollowed out, and will comfortably accommodate some 40 or 50 persons. It is splendidly furnished as a sitting-room, and contains every article of elegance and usefulness. It has a handsome piano, sofas, glasses, and mirrors, of fit and becoming style; and is decorated with pictures and fancy articles."

13. Of the *pines* of North America, Michaux describes fourteen species, some of which grow to a great size, surpassing in height all other trees of the forest, and are very valuable for timber. He measured near Norridgewock on the Kennebec the trunk of a white pine felled for a canoe, which was 154 feet long, and 54 inches in diameter. The greatest height attained in that region, by the pine, he states at about 180 feet.

Mr. Douglas, a botanist, who was sent out from London, in 1825, to explore the northwest coast of America, mentions two species of pines which grow to an enormous size. One of these species, called the *Pinus Douglassi*, found on the banks of the Columbia, grows, as he states, to the height of 230 feet, and is upwards of 50 feet in circumference at the base. The other species, called the *Pinus Lambertiana*, was found in Northern California. "One specimen, which in consequence of its having been blown down, Mr. Douglas was enabled to measure, was 215 feet in length, 57 feet 9 inches in circumference at three feet from the root, and 17 feet 5 inches at 134 feet. It is probably the largest single mass of timber that was ever measured by man; though some of the growing specimens of the same pine were evidently of greater elevation."—*Timber Trees.*

Lewis and Clark in their "Expedition," mention six species of firs or pines in the country watered by the Columbia, the largest of which is doubtless the same as that called *Pinus Douglassi*. "This species grows to an immense size, and is very commonly 27 feet in circumference, 6 feet above the earth's surface. They rise to the height of 230 feet, and 120 of that height without a limb. We have often found them 36 feet in circumference. One of our party measured one and found it to be 42 feet in circumference, at a point beyond the reach of an ordinary man. This trunk for the distance of 200 feet was destitute of limbs. This tree was perfectly sound, and at a moderate calculation, its size [height] may be estimated at 300 feet."

14. The *mahogany*, a tree found in the West Indies and the central parts of America, is highly valued for its timber. It is a tree of rapid growth, but supposed to be not less than 200 years in arriving at maturity; its trunk has often a diameter of 4 feet; and the timber of a single tree sometimes produces $4,000 or $5,000. The mahogany, or "*Swietenia mahogani*, is perhaps the most majestic of trees; for though some rise to a great height, this tree, like the oak and the cedar, inspires the spectator with the strongest feelings of its firmness and duration. It expands into so giant a trunk, divides into so many massy arms, and throws the shade of its shining green leaves, spotted with tufts of pearly flowers, over so vast an extent of surface, that it is difficult to imagine a vegetable production, combining in such a degree the qualities of elegance and strength, of beauty and sublimity. A single log, imported into Liverpool, weighed nearly 7 tons; was, in the first instance sold for £378; resold for £525; and would, had the dealers been certain of its quality, have been worth £1,000."—*Timber Trees.*

15. The *apple-tree*, though not to be compared, especially in height, to the large forest trees above mentioned, sometimes grows to a considerable size. Mr. E. Hall, of Raynham, Mass., states, that there are two *apple-trees* standing near his house, the circumference of one of which is 13 feet 5 inches 5 feet from the ground, and 12 feet 2 inches 3 feet from the ground; of the other, 12 feet 2 inches 1 foot from the ground, and 11 feet 6 inches 3 feet from the ground; and the reputed age 130 years. Mr. J. Ives states, that in Wallingford, Vt., there is an *apple-tree*, whose circumference is 8 feet 4 inches one foot from the ground; and about 50 yards distant from it, there is a *butternut tree*, the circumference of which is 9 feet 2 inches 18 inches from the ground; and that the branches extend over a tract of land 5 rods in diameter.—*N. E. Farmer.*

For the Farmers' Register.

ON THE ROTATION FOR GRAIN FARMS.

Many publications in the Register disclose a great difference of opinion on the routine of cultivation in a grain country; and some persons improvidently adopt plans without reference to the circumstances by which they ought to be governed. I possess no science in agriculture, and my opinions are the result of a limited experience; but I think the most profitable and advantageous system depends upon the quality of the soil, its state of fertility, and the means possessed for its cultivation. Large crops may be made; but the expenses may absorb all the profits. My aim is to combine profit and improvement. Many years ago, when actively engaged in other pursuits, I purchased a small farm, which had been greatly exhausted under the three-field system. I divided it into five, planted one in corn, in which I sowed wheat; and as soon as I got my fields set in clover, on clover fallow in addition. Under this system my lands improved, and my crops were good; the fallow generally yielding fifty per cent. more than the corn ground. A long-continued application of gypsum injured my wheat crop, but gave strength to the grass, which I found could not be subdued by a hoe-crop once in five years. Since that period, other lands have fallen into my possession; and having nearly relinquished all other pursuits, agriculture has become an object of greater interest. My lands are now divided into four fields, one of which I cultivate in corn, and another in wheat. I gather neither tops nor blades. My corn-field remains over a year, and is then sown in wheat, and the next spring in clover; after remaining two years in clover, it is planted in corn. I have some lots in orchard-grass, which supplied the loss of the fodder. The clover-field, at maturity, is surrendered to my stock. The advantage of this system is easily computed: the month of September, which was formerly spent in gathering fodder, is now devoted to manuring, and preparing my fallows. One good ploughing, rolling and harrowing will put them in good order, and my wheat can now be put in with ease and expedition. I select the most favorable time from the 5th to the 25th of October. I suffer my corn to remain in the field till the shuck becomes dry, which gives it I think a more perfect maturation; and in the time between sowing wheat and gathering corn, I can always find useful employment. After my corn is gathered, my horses, colts, dry cattle, and sheep are turned into my stock-field, where they find sufficient provision till the first of January, and sometimes till the middle. The shucks and straw are abundant for the winter, with a small allowance of corn for my horses. As an improvement to my system, I intend to enlarge my cultivation of ruta baga; for though you place this crop in the list of humbugs, I deem it very valuable, particularly in the spring, when cattle eat dry food with great reluctance.

The objection which I have heard urged to leaving a corn-field unsown, is, that the ground sustains injury by remaining bare. This has not been my experience. My corn is cultivated before harvest, the crab-grass and foxtail soon spring up; it grows luxuriantly till frost, when the cattle are turned into the field; they tread it into the ground, which I think tends more to improvement than forest-leaves, which are now extensively used in Virginia. Some of your correspondents speak of ploughing in clover in the month of June when in full bloom; by this and a second ploughing, harrowing, and rolling, a field may be well prepared for wheat; but this requires hands and horses dispensable at other periods of the year. In the month of June, I am under hard pressure in cultivating my corn, and cutting hay. I readily admit that a clover-fallow, in a state of perfect preparation, will produce more than a stock-field fallow; but I doubt if provident farmers are generally able to have their clover fallows in the best order. A gentleman who has seen one of my wheat fields within a few days, thinks, if there be no disaster, it will produce thirty bushels to the acre. My calculation is not so high. It is the nature of man to be confident of his own schemes and plans, and to attach little importance to those which differ from them. Of this the United States Bankmen, the Sub-treasury, and the Conservatives at Washington, have this winter afforded strong illustration; and probably, in my humble calling, I may be under strong delusion, but I believe a farm cultivated for ten years, with four fields of fifty acres each, and twenty separate acres for hay, with three acres of ruta baga in the corn-field, and worked by four men and two boys, would be of more value and produce more clear profit in this region, than under any other plan of cultivation.

I insist on the value of ruta baga. I have great respect for chemical experiments; but when experiment and fact are at war, I adhere to the latter. Fat cows, rich milk, and sweet yellow butter, are better proof of the nutritious properties of this plant, than the experiments of a legion of chemists. I think our encouraging prospects for a crop of wheat go to contradict the notion that the earth is waxing too cold for its production. It is strange how men of science differ. John C. Semmes, whom I take to be no mean philosopher, entertained the opinion, that there was a fine fertile country in the bowels of the earth, and that the Lapland deer entered it at the pole in the winter, and grew fat on the pastures; and with proper encouragement, he would have effected a settlement there, if he had found his theory true. Other philosophers hold that the whole is a mass of fire. Of the two, I rather incline to Mr. Semmes's theory; not from the lights of philosophy, but the impulse of taste. I do hope that the secretary of the navy will specially instruct the scientific corps attached to the exploring squadron, if they reach the Pole, to take a peep into the great hollow and fully ascertain whether it is filled with green pastures or burning fire.

RUSTICUS.

Eastern Shore, Md., 10th May, 1838.

REMARKS ON THE SOILS AND AGRICULTURE OF GLOUCESTER COUNTY.

By the Editor.

The agricultural traveller, or observer, who sees the county of Gloucester for the first time, cannot fail to be astonished, as well as delighted, with the general appearance and peculiar qualities of the great body of low-grounds; and his astonishment will not be prevented, or much diminished, by any previous account which he may have heard of this far-famed and highly eulogized body of land. At least so it was with myself. It was not that I had not inquired and heard much, and even of correct description, of the land and agriculture of Gloucester, from residents, or other persons well informed by long personal observation. But when viewing for myself, and for the first time, I soon found, as is often the case, that I had applied all accounts, before heard, to my own preconceived impressions, which were very erroneous, because made by other "low-grounds" and soils of entirely different character. Thus it is that so much of what we hear, and of what would otherwise be interesting or valuable instruction, is of no effect, and is either not noticed, or is forgotten almost as soon as uttered, because the narrator and his auditor have not common or accordant views of the things which are described; or of the opinions which serve as premises and ground-work for the reasoning and deductions. Hence it is, perhaps, that in addition to the want of fitness for the task, and of opportunity for careful and leisurely observation, of the reporter, that my sundry attempts in this journal to describe, and to furnish useful instruction by describing, some of the most interesting and peculiar agricultural soils and practices in Virginia, have had but little effect in spreading the practices which were described and recommended. For this want of common views and premises, it also often happens that a person is the less fitted to describe to strangers, because of his long and intimate acquaintance with the scenes and circumstances which furnish the subjects; and the reverse, that a new and even hasty and inaccurate observer and reporter may be more likely to seize on the most curious and novel points, and impress them the more deeply on others, who are as ignorant of the subject treated, as was the reporter but a short time before. I hope to be excused for thus presenting the claims of ignorance, or of very new and imperfect acquaintance with the subject, to make agricultural reports; for if that claim is not allowed, there will be but little of value left to mine, in this or in previous attempts, made under the like or greater disadvantages, of want of knowledge, and want of time and opportunity for proper observation.

Nearly half the boundaries of the county of Gloucester are formed by the wide waters of York river; but it is not on these waters, as I had supposed, and as most strangers suppose, that the district known as "low-ground" is situated. This great body of land is principally on the other side of the county, and consists of more than 35,000 acres in one body. It begins a little below Gloucester point, (opposite Yorktown,) on the lower part of York river, and includes the whole country to the North river. The short rivers Severn and Ware cut through the low-ground, and the extent of these and of North river, as exhibited on the map of Virginia, shows the breadth of this great body of land. The Severn, Ware, North, and East rivers, are, in fact, not rivers, but merely arms of Mobjack bay, which itself is a broad and deep indentation of the great Chesapeake bay. North river is between Gloucester and Matthews; and East river is wholly in the latter county; but I have named them with the others because all join to form Mobjack bay, and because the continuous level body of low-grounds, of similar appearance, general character, and geological formation, extends across and around the whole; so that a very uniform face and character are presented on all the Chesapeake slope (if that may be so called which is almost a dead level,) of the peninsula formed by the York and the Piankatank rivers. The same marked and peculiar character which distinguishes the Gloucester low-grounds, belongs also to the Back river lands in Elizabeth City; which, like the former, also lie on the refluent waters of Chesapeake bay. Indeed, the Back river lands, which I had before slightly viewed, and which are described in Vol. III. of this work, (page 414) are as much like the Gloucester low-grounds, as if they were part of them. The principal difference is, that the Back river soil contains gravel generally, and sometimes rolled stones or pebbles, both of which are entirely wanting on the Gloucester flats.

Almost every stranger would suppose, that the rivers are merely *bordered* by low-grounds; which, however broad they might be—even if a mile wide—(and my imagination did not stretch farther,)—were separated by ridges, or projecting points of higher land, dividing the waters of each two contiguous rivers. But not so. Though there are numerous and frequent variations of level, yet they are so slight, that the eye can scarcely distinguish them with certainty, or know whether the general inclination of surface, for a mile or two together, is as it may appear, or directly the opposite. It is not by trusting to the eye, but to the standing and flowing of rain water, and other certain indications, that the levels of the surface are known; and to the sight alone, the whole of this great tract, varying from two to more than six miles in width, (or more than the whole length of the short rivers which cut through it,) and from the mouth of York to the mouth of Piankatank in length, is an almost perfect level, elevated but a few feet above the tide-waters which intersect the country.

The "high-lands," which, by an abrupt and very marked change, form the land or western boundary of the low-grounds, are as different as one soil and surface can well be from another. The distance of twenty yards, and often much less, will generally take the observer from low-ground, having all its peculiar marks and qualities, to high-land possessing none of them. For the present, my remarks will be confined to the low-ground district.

The four short rivers are merely creeks, filled with the refluent waters of the Chesapeake. They receive but little spring or fresh water in streams, and therefore they furnish almost no alluvial deposite, to have formed, or aided in forming, the low-grounds. But though not indebted to the usual mode or source of alluvion, this great and valuable body of land is not the less certainly formed by deposites of the water. But it must have been an oceanic, and not a river deposite; and I entertain no doubt, but that the land once was the bottom of the Chesapeake bay, and afterwards up-heaved by some ancient convulsion of nature, as, more recently, other regions have been known to be, so as to be raised above the waters which once covered it, and to which it owes its singular formation, and great fertility and value.

Contrary to the usual mode of describing soils, I shall begin with these at the *bottom*, or at least as low as the foundation is yet known. This is believed to be one entire and continuous body of what is here and elsewhere erroneously called marl; ancient sea-shells, broken down, disintegrated, or by their softness ready to become so; which bed is seldom more than six feet below the surface, frequently not three, and sometimes near enough to be cut into by the plough; and which reaches lower than any digging for wells has yet been carried. Wells, however, generally reach enough water within 6 or 8 feet, sometimes within four; and the deepest diggings heard of were in one well of sixteen, and another of twenty feet; and of these, for all but the upper three or four feet, the digging was in these shells, or marl. The earth on the marl is always wet with veins of spring-water, and generally it is sufficiently abundant to supply a well, dug any where as deep only as the marl, and sometimes before. There usually lies over the marl a reddish yellow layer of sand, having enough of clay to be adhesive, and which varies in depth from an inch, or less, to more than a foot. Upon the authority of a good practical farmer, Mr Simcoe, who lately died, it was said that this yellow earth, as thrown out of the ditches, had been found to be a valuable fertilizer; and hence it was supposed by some, to be calcareous. But upon testing it, I found that it was not in the slightest degree calcareous; nor do I believe it can have any valuable effect as manure, unless it were desired to furnish iron, or sand, to the soil. It was probably mixed with the marl lying immediately below, and which also is very often thrown out in digging ditches of not more than 30 inches depth; and thus it might have become a manure by that admixture.

The low-ground consists of what is called gray land, black land, and a small amount of a third kind, called the chocolate-colored.

The gray land is a clay loam, of the color indicated by the name, close in texture, and lying on a very intractable clay sub-soil, which, when dug up from ditches, does not lose its barrenness by time and exposure. The gray land forms the larger proportion of the whole, and exclusively forms the points which run down to the rivers, made by their very crooked courses, or between their branches. Hence, in such places, this kind is also called "point-land." These points of gray land are a little the highest; and on them, and close to the margins of the rivers, are most of the mansion-houses of the proprietors situated. Before being cleared, this land was covered by a growth of large oaks; and though low and wet, was not often covered with water. The early and best product of such soil was not more than 20 to 25 bushels of corn to the acre. It is a better soil for wheat than for corn. Much of it is now reduced to a much poorer condition, by long-continued scourging tillage. But some has been much improved by manuring, and the better system of farming which is now getting into use; and many farmers say that this soil, when so improved, is more productive and valuable than the more celebrated black lands.

The black lands are interspersed on the surface among the gray in a very irregular manner, and of which there seems to be no sufficient explation, except in the supposition of the original formation of both which I shall offer, however wild and ridiculous such speculations may be considered. While the gray land seems to be exposed at the surface in the form of long, though low and wide points, narrow streaks or ridges, and circular prominences, all of which are but very little higher than the adjacent and interspersed bodies of black land, the latter seems to have such outlines as ponds of water might be supposed to have, if bounded, or separated, by the gray land. And such, I think, was the former condition of both. The gray land formed the entire surface, with such slight variations of level as had been caused by the different currents and eddy waters, when covered by the Chesapeake. When the highest parts were raised above the height of the tide, fresh water, from the springs and rains, filled the lower parts, rendering them shallow ponds, gradually becoming changed, by the growth, decay and deposite of vegetable matter, to swamps; and which now form the black lands. so celebrated both for their original and very durable fertility. According to these views, the original gray land, should be the sub-soil of all the black land; and such appeared to me to be the case, notwithstanding all the present existing differences of the two sub-soils. Both are stiff, tenacious, and very intractable clays; difficult to penetrate when dry, and difficult to clear from the digging implement, when wet. But while the sub-soil of the gray land, when thrown up, remains barren, that of the black land, though cutting like putty or pitch, when moist, and forming very hard clods when first dry, moulders down, after exposure, even though but to summer weather, and becomes finely pulverized, mellow, and fertile, so as not to be distinguishable from the black upper soil. The cause of this difference of the sub-soils, I infer to be this. All, as stated before, lie over a continuous bed of marl; but, according to the supposed formation, that under the black soil is of much the least thickness. It is, even now, penetrated by the craw-fish, (or cray-fish,) which sink their curious wells and dwellings from the surface of all the black soil to the marl below, and bring up the shelly earth, to form their buildings above the surface; and the annually renewed labors of millions of these little well-diggers, continued for ages, must have had no inconsiderable influence in rendering calcareous the black soil, and also its sub-soil, through which they pass. The craw-fish do not bore in the gray lands. But a still greater operation of this kind has been carried on by the growing trees; which, by their roots penetrating the marl below, drew up lime continually, and by their subsequent death and decay, deposited all the lime, thus incorporated in their substance, on the surface of the earth.

These geological speculations (if they may be dignified by that name,) may appear to some as foolish, and to others as idle and unnecessarily brought forward, even if true. But any plausible theory of the formation, and cause of the peculiar features, of this region, is not foreign or useless to an investigation of the nature of the soils; and this theory seems to me in perfect accordance with the now existing circumstances. This will be further seen in the following as well as the preceding parts of the description.

The soil of the black land, when moist, or just turned up by the plough, is as black as any can well be; and even when dry, is so much darker, as to be easily distinguished from the gray. It is mixed with a large proportion of vegetable matter, even when worn by exhausting cultivation for many years. From its being very favorable to the growth of white and red clover, melilot, and other products of calcareous soils, it is evident that much lime must have been drawn from the marl below, by the trees, or otherwise, and fixed in the soil. And this lime still remains in the soil, though it is not in the state of *carbonate* of lime. The soil is not generally calcareous; but is *neutral*, according to the doctrine of acid and neutral soils presented in the 'Essay on Calcareous Manures.' If any of the black soil has calcareous earth, exceeding the acid, and the vegetable matter, with which it combines, and therefore would show the presence of some carbonate of lime, it should be such as had been among the richest originally, and the most retentive of fertility under as long-continued and severe cultivation as any part has borne, and to which no manure had ever been given. From just such as this, I selected for trial, a specimen, at Warner

Hall, the farm of Colin Clarke, esq. The specimen was subjected to a very delicate and sure test, which gave evidence of the presence of an exceedingly minute proportion of carbonate of lime; but so small, that it was impossible to measure it, and certainly not equal to one grain in 10,000 of soil. This therefore, substantially, is a neutral soil. The gray has generally a sprinkling of sheep-sorrel; which proves sufficiently that the soil is actually, though but slightly, acid; and needs calcareous manure to remove that noxious quality, as well as for the other advantages, which the black soil might also derive, in a less degree.

Very little of this black land remains now in its natural state, in wood and almost under water, as all such was formerly. But at Warner Hall there is a large body (300 acres) both of black and gray soil in a state of nature, and which I examined carefully, and with peculiar interest, as furnishing the best indications of character. In this natural state, and at this time (May 12th,) and through winter and spring generally, the uncleared black land is truly what it is called, "swamp land." The soil is saturated and in many places covered by water, from rain, and it is troublesome to ride over the miry surface, and impossible to walk, except through soft mud and water. The larger growth is black-gum, of great size, white or sweet-gum, ash, sycamore, and other trees seldom found on high and dry lands. The papaw is very abundant, though generally of small size. When new, the black land is of the highest grade of fertility; and even under great defects of drainage, produced 50 bushels of corn to the acre. Under tillage, the soil becomes as finely pulverized and as light as can be in any case; and therefore it is not as well suited for wheat as for corn. After many years of scourging cultivation, and without manure, (for that was rarely given to any of this soil,) the black lands, thus abused, can yet produce 25 or 30 bushels of corn to the acre. I saw on the land of Major W. K. Perrin, on Ware river, a growth of very fair red clover, regularly and thickly set, on a field which had been for the ten previous years under the two-shift rotation of corn and wheat, and probably not rested from grain tillage, even one year, in the many that have passed since the land was first cleared.

The soil of the black land, though so light under tillage, is mostly a stiff and very tenacious clay loam when ploughed up, and while moist. Some however, as on parts of Whitemarsh, the farm of John Tabb, esq., is found much more sandy. The soil is very deep, say one to two feet; and it then changes to the stiff but open clay subsoil which has been already spoken of. Still lower, the clay is blue, close, and very heavy when dried, after being worked into a mass when wet. Still, like the upper clay, this also crumbles fine by exposure, and becomes good soil.

The clay shores of Mobjack bay, where left naked at low tide, seemed to my view to be not very unlike the clay soil of the gray land; and the shallows in the Chesapeake, stretching from the lower end of Gloucester, are composed of naked and solid marl, such as forms the lowest stratum of the low-grounds. This probably lies under all the adjacent shoals of the bay, and likewise under the marshes, which, though covered frequently by the tide, and always as wet as possible, are yet so firm that I rode briskly and easily across many acres without any danger of miring. In the firm parts of these marshes, shores, and still lower shoals, is presented another body of Gloucester gray land, which wants nothing but elevation, to be the same with such as is now distinguished by that name. But enough of uncertain speculation.

Of the "chocolate land" there is but little; and I saw none except that which is part of the farm of Jefferson Sinclair, esq., at the mouth of Ware, or rather on Mobjack bay. The marl there, under this chocolate land, is so near the surface as to be generally within reach of deep ploughing; and the common ditches of the farm sink so deeply into it, that from one-fourth to one-half of their banks is composed of a very rich marl. Thus, merely by ploughing, and by carting off the ditch banks as manure, the land is made more and more calcareous; and was probably so to a considerable degree before cultivation, as the rich marl is at so little depth below the surface. This marl, by its yellowish red color, seems to contain much iron; and to this, as well as its calcareous quality, is probably due the reddish-brown color of the soil, from which its name is taken, and also its remarkable productiveness. This kind is the most valuable land in Gloucester.

This land was, not many years ago, a shallow pond, covered with water-plants and gall-bushes, and was celebrated as a place of resort for wild ducks. This, as well as the greater part of the whole farm, is so low, that high tides flow up into all the ditches, or, at least, did so flow, until a bank was made and flood-gates erected, to exclude the tides. But though lower than any other arable part of the country, this land was decidedly the driest, when visited. The marl on which it lies appears to be an almost unmixed mass of finely broken fossil shells; and this very open stratum, though so little above the level of common tides, and though always wet within a foot or two of its top, yet serves, by its openness above, as a complete under-draining to the land.

Two specimens of this marl which I selected, as apparently presenting the average richness in calcareous matter, when analyzed, gave products of carbonate of lime, (or pure calcareous earth,) the one of 76 parts in the 100, and the other 72. The first was of the most usual appearance, consisting of very small, or broken and loose shells, mixed with either the oxide (or rust) of iron, or clay of that color. The last specimen was in parts tinged deeply with green, by a fine green clay with which it is mixed. The chocolate soil lying above this marl is every where mixed more or less with fine particles of shells, perceptible by the eye. A specimen selected from ploughed land, and among the best in productiveness, yielded 6 per cent. of carbonate of lime. This was more calcareous, to the eye, than many other parts, but less so than others. No marl had ever been carted there. But as very deep ploughing will almost every where bring up marl to mix with this soil, it is difficult to select an average specimen; and impossible to know whether the soil was partially, and to what extent, so mixed by nature, or by cultivation. Mr. Sinclair has made as much as 14 barrels of corn to the acre on some of this land. It produces clover finely; and part then had on it (after clover-fallow) the finest wheat which I saw in Gloucester.

Of other marls of the county of which I took specimens for analyzing, the following were the several proportions of carbonate of lime found.

White marl, from beneath black low-ground soils, taken out of a ditch 2½ feet deep, on Warner Hall, the estate of Colin Clarke, esq., contained 58 per cent. of carbonate of lime.

Three specimens from the diggings on the high land of John Tabb, Esq., surrounding the court-house—

No. 1, yellow marl - - -	69 per cent.
No. 2, yellow - - - -	57 per cent.
No. 3, blue - - - - -	36 per cent.

Two specimens from the high-land part of the farm of W. K. Perrin, Esq., on Ware river—

No. 1, at the bottom of the digging,	47 per cent.
No. 2, from the top, - -	52 per cent.

When compared with marls of 70 to 80 per cent., and even richer kinds, of which reports have been spread abroad, it may be that the poorer of these kinds may be thought too weak for use; and therefore the statement of their degree of strength may even discourage the working them. There is a general and very erroneous fastidiousness on this subject. Many are anxious to marl if they could be sure that their banks are rich enough; but would be reluctant to commence, and doubtful of the profit, with their marl, if its strength were supposed or proved to contain less carbonate of lime by 30 or 40 cent. than some other kinds. It is undeniable that such differences are very important; and that marl of 80 per cent. is worth per bushel twice as much as that of 40, and four times as much as that of 20 per cent., other circumstances being equal. Nevertheless, they who cannot use richer, may be well content with making proper applications of the poorest qualities. The facility of applying a very poor marl, may make it cheaper to give of it to the land a certain amount of calcareous matter, (the only object of the application,) than from a bed twice or thrice as rich. My own marls used during the first years of my practice, and through the first 400 acres covered, did not average, throughout the work, more than 38 per cent.; and in addition, and what is more important, the average difficulties caused by depth of the over-lying earth, the wetness of the marl, and the high hills and the distances over which it was generally drawn, were unusually great, and very far greater than any required in Gloucester; and that, nevertheless, and in spite of all the errors and losses caused by want of experience, and of any practical guide, these labors were more effective, and have resulted in a higher degree of continued improvement, and more net profit on the investment, than is known of any other prior improvements elsewhere, or of any made since, by other means than marling or liming. I have used, and in great quantities and with results entirely satisfactory, a body of marl which had barely 20 per cent. of calcareous earth, and the other remaining four-fifths of worthless sand. These statements, and the egotism, may be pardoned for the lesson which they convey, to all who hesitate to use marl because it is not richer than 30 or even 10 per cent.

The highest point of the ridge of high-land in Gloucester, is generally a loam of moderately close texture. The slopes are more sandy. All the high-land that came under my view, seemed to be of that defective natural constitution which makes marl necessary, and which will return the largest profits for its application. I saw only one farm where it had been applied generally, or to great extent, as well as to great advantage. This was Dr. Wm. C. Taliaferro's. But several other gentlemen, though later beginners, have also done much in marling on the high-lands.

It has been said that the variations of level, throughout the whole extent of low-ground, are scarcely distinguishable by the eye; and not at all, except to close inspection. The view extends without interruption for some twenty miles over the low-ground; which, so far as the eye would indicate, is one perfectly level and unbroken surface. Though almost every farm has more or less of wood-land, the proportion is small, to the quantity of open and arable land; and without intercepting much of the circle of vision, or range of view, the woods add greatly to the peculiar and striking beauties of the landscape. I never had exhibited to my sight more beautiful scenery, than from several different points on the brow of the hill, or long ridge of high land, which forms the land boundary, and every where overlooks the low-grounds. Among these positions, are the mansion house on Whitemarsh, that of Col. Thomas Smith, near Ware river, and Zion Hill, a neat little church which overlooks the winding North river and the numerous farms on its borders. The wide extent of fertile or apparently fertile land, seems perfectly level, and the surface unbroken except by the waters of the rivers, which, seen in various turns, and between different bodies of wood, or other obstructions to the view, appear like so many detached lakes of clear and placid water. To a farmer's eye, the agricultural beauty still more heightens that of the landscape. The fields are generally divided by very neat fences, which, as well as the numerous ditches, are so placed as to make the dividing lines straight, and generally at right-angles; and thousands of acres of such regularly-shaped fields are spread before the observer in all the variety of naked or newly ploughed dark soil, and the different shades of green of the fields of wheat, barley, oats, clover, and natural grass on the pastures. The waters and the woods fill the remainder of the picture, which is further heighened in beauty by the numerous mansions and other buildings, on neighboring low-ground farms; and to the prospect there is no limit, save that fixed by the feebleness and imperfection of the power of seeing. From the elevated site of the Whitemarsh mansion, these general and uniform features of the low-ground scenery are exhibited to great advantage. But in addition, there is also an unusually large proportion of black soil, and of luxuriant crops, in the fore-ground of the landscape; and the waters of two of the arms of the Mobjack bay, the Severn on the right and the Ware on the left, are in full view, and the waters of the wider parts of these bays are seen spread out in the distance, and over the tops of the intervening trees, and the whole so separated by land and by woods, as to appear like many lakes, varying from very small to very large size. From the same point of view, vessels may also be seen sailing on the North river, though the water is too far distant to be visible. When seen soon after sunrise, or before sunset, and in the position to show the ruddy glow of the sun's reflected splendor, each of these seeming lakes deserves to be compared to a "sheet of burnished gold," fully as much as Scott's Loch Katrine. There is another appearance of the sun-light on the water which was to me more novel, and therefore still more striking. Between 8 and 9 o'clock in the morning, when riding along the ridge of the high-land, I came in sight of the distant and wide waters of the Mobjack, or perhaps of the main Chesapeake beyond. These waters, thus seen over the tops of high woods, always presented, to the unaccustomed eye, the optical delusion of the water appearing full as high as the tops of the highest trees; and in addition, in this case, the water being directly beneath the sun's position, received from it no red or fiery reflection, but the white and dazzling brilliancy of snow, seen in bright sunshine.

There are other and great beauties of these winding and narrow sea-creeks or bays, which are improperly called rivers, and which misnomer serves to convey very false ideas of these waters. To me, and probably to most other inhabitants of lower Virginia, there are associated with a small tide-water river, the ideas of head-streams contributing irregularly, but largely, to the supply of always muddy water—muddy shores, and the margins bordered and deformed in many places by large miry marshes—and these visible characters inseparably connected with the stench of decaying vegetation, and the certain production of disease. But very different are the features of these arms of the Mobjack bay Except the Ware, none of them receive but a very small supply of fresh water from springs, streams or rains. They are filled with refluent sea-water, as clear as crystal, and pure except for saltness. There is very little marsh on either, and on North river, none; which, by giving clean and firm shores every where, renders that river and its margins more beautiful than any other. The general level of the low-ground region is supposed to be not more than six feet above the height of common high tide—and generally less; and as there is no sensible decline to the water's edge, the waters seem to fill their broad basins to the brims. The very winding courses of these waters present continued changes of prospect, and yet almost always that of lakes. Though every one of the numerous mansions on the North river farms, as on the other rivers, is placed close to the water's edge, still the crookedness of the course serves to scatter them over a wide space, and prevents that uniformity of appearance that would be expected from such an arrangement. The waters of North river, especially, confined by such banks, are beautiful; whether seen in calm repose, or enough affected by the wind to crest the sea-green waves with white foam. It is, with all its accompaniments, a scene, and a condition of things, more like romance than real life; and to a writer of romance, I would especially recommend the North river of Gloucester to furnish both scenery and subject matter. But it is full time to return from this digression from my proper subject.

It is not unlikely that the uniform level of this region may appear too monotonous, and become wearisome, when the novelty is over; and also that this feature is the more pleasing to me, from another early association of ideas, which is not always correctly applied here. Very low and level land, wherever I have known it before, is also very rich land; and this idea gives the more of agricultural beauty to this extensive flat, because the fertility of the whole, as seen indistinctly in the distance, is raised by the imagination much higher than would be found real, upon closer inspection, and longer acquaintance.

It is not my purpose here to describe the farming in general, or any of the practices with particularity. For this, I had neither sufficient time, nor opportunity, stranger as I was to every thing in the county. A very slight sketch is all that will be attempted.

The rotation most in use on the low-grounds, is the three-shift; of 1st, corn, 2d wheat, barley, or oats, 3d, *rest*, as it is called, which is grazing, either on clover, or without. The two-shift rotation, which is simply that of the first two years of the other, and, of course, without any rest from an annual crop of some kind of grain, was formerly general, and is even now still pursued by many. None but excellently constituted soil could have so long borne so scourging a course as even the mildest of these two; especially as very little manure was used, until recently, except on a few farms. Five years ago, clover was sown but on a few spots, and to a very limited extent, though now it is on almost every farm, and usually covers a large part of the field which is third in the course of crops. In addition to this late and vital improvement, I was told by several farmers that the whole quantity of manure now used in one year, is tenfold greater than a very few years ago; and that a strong and effective impulse has certainly been given to the general improvement of agriculture in the whole county. This impulse, in part, was said to have been received from the contents of the Farmers' Register. Of the correctness of this supposition it was not for me to judge; and if otherwise, it would have been too gratifying, to be much questioned, or severely scrutinized.

Besides the manures furnished by the offal of crops, passed through the farm-yard, or stable, as elsewhere, the improving farmers of the low-grounds have found and have used, and are yet in the course of using, great and valuable supplies, in the ancient accumulations of oyster-shells and rich earth, &c. made on all old settlements, either by the present inhabitants, or the aborigines. In some few places, the Indian banks of oyster-shells still cover acres of their former towns, and would furnish much of calcareous as well as of enriching manure. But the more recent accumulations are those mostly used, and these also were large, as the removal had been long neglected. Of the great body of marl, lying under all the low-grounds, but little has been used as manure, and there is too little confidence, in general, in its profit on the low-grounds, to induce the application. Some farmers, however, are zealously engaged in marling the low-grounds, and already consider their outlay well repaid. Capt. Tabb, on North river, is as yet the most extensive marler of low-ground; and he thinks that whoever has enough leaves or woods-litter, to apply with or after marl, can make his farm as rich as he may desire.

Though I would strongly urge the marling of *all* the low-grounds, (unless any part be already sufficiently calcareous,) and would expect great profit therefrom, considering the uncommon ease and cheapness with which the manure could be applied, still, I do not expect from it any thing like such large increased products to the acre, or per cent. on previous products, as is found on soils naturally poor, and of much less value than these. But much of this land could be marled so cheaply, that an increased clear product of only one bushel of wheat (at present prices) or 200 lbs. of clover-hay, would amount to near or quite 100 per cent. of annual and permanent profit on the investment. On the gray lands (unless marled from the black,) the expense would be greater, and likewise the product, as these lands evidently need marl to neutralize their acid quality, as well as to store up and fix putrescent matters. On the poor high-lands there are many farmers using marl; and what is the more gratifying, and the stronger evidence of the manifest profitable returns, I was told that it is mostly among the poorer class of farmers that these improvements are to be found. Marl is found in almost every ravine cutting through the high-land, and along the whole Chesapeake side of its steep slope. In the black low-grounds, the ordinary ditching, of two and a half feet depth, often reaches the marl, and sometimes it forms the bottom of a ditch for half a mile together. If all the ditches were deepened, the same operation would serve to drain the land better, of subterraneous spring water, (which operation is much needed,) and to furnish marl, in the cheapest manner, for all the adjacent ground. If there were any need to increase the already great facilities for water conveyance, level navigable canals, might be extended from any one river to another, or all the way from York river to the head of North river, by digging not more than from 6 to 10 and very rarely perhaps 14 feet, and the lower part would be in solid marl throughout; and, thus, if properly located, and on a general and uniform plan, the same excavations which would be profitably made for obtaining marl alone, would also furnish deep drains for the land, which would be very beneficial, and also might carry any desirable depth of tide water, and navigation, at the same time. I merely mention this as illustrating the remarkable natural facilities offered for these operations; and not to recommend their being thus combined. For though, even on such a combined plan, the marling here could be effected far cheaper than in most other places, where that is the sole object, yet it may be done here much cheaper still, by digging in the spots where the marl is nearest the surface, or nearest to the land on which it is to be applied. High as the stratum of marl lies, still it is beneath the surface and level of land naturally wet, and seldom sufficiently drained. Of course the marl is wet, and usually after being dug into, two or three feet, furnishes enough water for permanent wells. These difficulties are greatly and erroneously magnified by the imagination of those even who desire to use marl, or who have tried digging at "leisure times," (that is in winter, or wet weather, unfit for cultivating the soil,) and always without any proper plan for keeping water from impeding the work. It is always important, for saving labor, and for marling cheaply, and to any great extent, that wet diggings should be drained as effectually as the location admits; and, every where, that the marling should be carried on as a regular and continued work, throughout the year, or through all the best season of it. But no where would more advantage be gained by following these two rules than here; and by the neglect of both, in every case, great obstacles to the work have been created, and suffered to operate most injuriously. No general plan for excavating marl in such situations can be prescribed in advance of practice, and without some experience of the nature and circumstances of the bed; but I may venture to assert that the cost of pitting marl here would be reduced to half of that of any of the work already executed, by attending to the following general directions. First—to sink, from the intended pits, a ditch, to bring off the water, as low as an outlet can be well obtained; and that would generally be as low as the tide water. Secondly, to keep the area of excavation as well drained as possible. And thirdly, to keep at work regularly throughout the year, or to suspend operations only during the depth of winter, if that season should be attended with much increased difficulty. Without thus making it a regular and continuous job of work, I may venture to foretel that no man will do much at marling on the Gloucester low-grounds. The most that has yet been done, except on a very few farms, is in carting off the ditch-banks, to level them, as well as for manuring; and as many parts of these are mixed largely with marl, the earth gives calcareous, as well as enriching manure. In any such mixture, however, the share of benefit due to the marl alone cannot be exactly known; and it is therefore seldom fully appreciated. But, whether it is owing to this chance-made and little-valued admixture of marl, or otherwise, all persons are satisfied of the profit of using, as manure, rich banks of ditches, scrapings around old dwellings, (which here are always calcareous, with oyster-shells as well as ashes); and these manures have been used and are still in the course of application, to great extent. Many of these applications are, in fact, *marling*, or adding calcareous earth to the soil; though that, the most important action of the manure, is never duly appreciated, and sometimes perhaps not even known by the persons deriving the benefit.

Wheat is considered here a more uncertain crop than in general, and especially on the black lands. Indeed, one of the best cultivators and most successful and judicious farmers, the deceased Philip Tabb, pronounced that these black lands would not do for wheat-culture; and his opinions had so much weight, that it was one of the causes why barley was made, for a long time, almost exclusively the small-grain crop after corn. All this region is colder in spring than on the tide waters of James river, owing to the great exposure to easterly winds, and their prevalence. I suspect a still greater cause of injury to the wheat is the want of draining, notwithstanding all the labor and care used for that object; and the land being always, in winter and spring, injured by excess of water, either on the surface, from rains, or by sucking up moisture from the veins of springs below, and which may be reached by shallow digging every where. Both of these evils are perfectly within the farmer's power to remove; and with their removal, I think that much of the supposed unfitness of the black lands for wheat will disappear.

Next to corn, barley had here long been the most important market crop; and I have never heard of its being successfully raised elsewhere in Virginia, or even a single trial succeeding well enough to induce repetition, except on the similar black lands of Back river, where also it has been an important culture. Hence I infer that a soil of peculiar and uncommon constitution is necessary for barley, and that the peculiar quality required is a proportion of lime very unusual in the natural soils of Virginia.

But, some years ago, barley also became here a very precarious crop. The most promising crops were sometimes speedily and almost totally destroyed by myriads of caterpillars; and, in one season, by some other unexplained fatality, all the fields of barley failed. These disasters caused the sowing of this grain to be greatly reduced; and, though since increasing, the culture in general still remains but small. Another objection to this crop is the uncertainty of the market, and the great fluctuations of price. Barley is used in this country only for making malt liquors, and the demand is therefore necessarily small.

Corn is the great crop of Gloucester, and is always a sure product. To favor the cultivation of corn, it would appear, their mode of tillage is especially directed, and to great loss and inconvenience in the other crops of broad-cast grain and clover. The fields are universally kept in narrow beds, laid off generally precisely five feet in width, but sometimes an inch or two wider, and sometimes as little as four feet ten inches. The general width, however, is five feet. One object of these narrow beds is to save labor in tillage; as four furrows, thrown by a two-horse plough, serve to reverse these beds, by lapping the first two slices and covering over eighteen inches width, unbroken, in the old alley, or water-furrow; and four other furrows, with a one-horse plough, when the corn is well advanced in growth, will sweep out and cover the whole interval between the rows, throwing the slice towards, and up to the plants. But even if labor is saved in corn-tillage, (of which I am not convinced,) it is greatly increased by having such narrow beds for broad-cast crops of grain or grass. The sowing, and getting in the seed, must be much more troublesome, always imperfect compared to flat tillage, and the reaping or mowing as objectionable in both these respects. But so much do habit and long usage lessen our estimate of difficulties and losses, that none of the farmers with whom I talked thought these objections to narrow beds of much importance. My objections, however, are not wholly theoretical, but sufficiently confirmed also by the practice of several years, and on entire fields of a large farm.

But the most important object designed to be gained by this plan of narrow beds, is the better drainage of a flat surface; and it is an opinion here universally established, that by wide beds that object could not be so well attained. To prove this, the fact is adduced, that many persons tried throwing two beds into one (of 10 feet) when sowing wheat; and that the plan was found bad for drainage, by there remaining a sink in the middle of the new bed; and bad for the subsequent tillage of corn, when these wide beds were to be brought back to narrow ones. I admit fully these objections to this particular departure from the general plan, which is far from such as I would approve; but nevertheless hold to my objections to narrow bed culture, not only for the tillage considered alone, but as a means for surface-draining. As I consider the plan which I would propose to substitute as an important improvement, and of which I have practically and satisfactorily proved the value on my own lands, and as it seems peculiarly suited to the Gloucester low-grounds, I will state my views at length, and presume—ignorant and inexperienced as I am as to these lands—to offer advice as to their management, to those who have been long and well acquainted with them. Of course, such opinions and such advice will be considered of very little value, and deserving of but little notice.

Compared to the proper drainage of the surface, the mode of tillage is of but minor importance. So much more of the facility of cultivation and of the amount of product, would depend upon the drainage than upon any other part of the management, that I dismiss any objections to narrow beds on the score of waste of labor, or waste of product; and shall consider the shape given to the surface solely in connexion with its most important object, the relieving the surface of superfluous moisture.

It should be remembered that the surface of these low-grounds receives no rain-water except that which falls directly on them; and that all of that must be either absorbed by the deep soil, or the surplus part slowly conveyed to the ditches, by water-furrows and shallow cross-drains. No water can otherwise run off, because the surface has no descent; and none can sink, as on higher and more sandy and open soils, because the sub-soil is a compact and tough clay, impervious to water. Of course, the object of the cultivator should be so to slope the surface as in the best manner to effect and to hasten the departure of all the excess of rain-water, beyond the wants of the soil. This is said, by the Gloucester farmers, to be done by narrow beds; and I maintain that it would be much more effectually and cheaply done by very wide beds, if properly made and preserved.

In theory the narrow beds promise well; and I have noticed that their advocates always refer to them in a state of perfection, which is rarely found in practice; and which, if greatly departed from, seems to defeat their object. If the narrow beds are separated by open, clean water-furrows, (called alleys in Gloucester,) well graduated, and having unbroken, and therefore not very absorbent, bottoms, over which the water will pass to cross-drains and to ditches in the lower places—then there is in fact a small but open and effective ditch in every distance of five feet. But this perfect condition is seldom attained; and even if attained, by great care and pains, is lost, or greatly impaired, by every ploughing, or other tillage operation, when the field is in corn; and even by the growth of plants, (when they can be made to grow in the alleys), when under a broad-cast crop. When under a tillage crop, and the water-furrow is choked by ploughing or harrowing the beds, of course they will be cleaned out soon after. But if a heavy rain falls before that operation, the surface of the land is as little fitted to discharge superfluous water, as if no beds or alleys had been made. Indeed, in such cases, or when the beddding is badly executed, the water-furrows are no better than indentations which serve, not to discharge, but to receive and retain the excess of water.

But it is yielding too much to suppose any thing like the perfection of execution, at any time, described above, even when most perfect. Such a state is obviously impossible. In what is considered land well bedded and water-furrowed, the bottom of every furrow is but a succession of long shallow depressions, separated by slight bars of ground, more elevated naturally, or left so by more shallow cutting of the plough in such spots. Of course, all these depressions, when filled by rain, are so many little ponds; and even if not more than an inch deep, the water must stand in every one until evaporated, or slowly sucked up by the already over-gorged soil. As the soil of the black land is generally too deep to be cut through by the ploughing, and is moreover very absorbent, the disappearance of this water there must be more generally caused by absorption than by evaporation. The slight and numerous inequalities of depth, referred to, are such as it is impossible to avoid leaving on the most level land, in ploughing, and of which the depressions are too small and too numerous to be cut through and relieved by cross-drains, or grips, as they are called elsewhere. These cross-drains are now always made, and serve well, wherever there is any considerable natural depression (say even as little as 4 inches) stretching across the direction of the beds. But serviceable and well constructed as these may be, the number necessary to be made, and their being filled, and requiring opening, at every tillage process, are also serious difficulties. And when these cross-drains are caught, not properly opened, by heavy rain, the evil is so much the greater than in the case of alleys, because one of these grips is designed to receive, and discharge into ditches, the water from hundreds of beds. The grips are, and for convenience ought to be, but very little lower than the bottoms of the water-furrows; and therefore both are necessarily bottomed on the absorbent soil of the black land.

When there is more careless and slovenly ploughing, and surface-draining, all these objections are still greater. The beds under wheat have frequently an average though unequal width of a foot or more in the water-furrow, on which the plants have been entirely killed by standing water; the less, though still highly injurious, effects of which must have extended higher upon such narrow and necessarily low beds. On some land, the wheat plants stood throughout the furrows, and this was made a claim of merit in the system, and in the execution. But if the plants of wheat live in so low a place, through winter, as on the bottoms of the water-furrows, I infer either that the plants, though living, cannot be healthy and productive; or if productive, that the soil was, in fact, so dry as not to need a drain every five feet to keep it well drained. Upon the best executed bedding, surely the bottoms of the water-furrows must be more exposed to wet than would be the whole surface, if there were no water-furrows.

But, even on the plan of narrow beds, I do not consider it better that the whole alley should bear plants. I would prefer the entire absence of them on a narrow, but clean furrow, as best for both drainage and for immediate product.

Now for the proposed substitute.

Supposing the land to be already laid off accurately in five-feet beds, five of these should be thrown together, by a deep ploughing, so as to form beds of twenty-five feet. It should be done by beginning at, and lapping two furrow-slices on the crown of the middle bed of the five, and then continuing to plough "in-and-in" until the plough at some place touches the water-furrow in which the new one is to be left. Then the plough should stop, at the end of that furrow, and begin upon the intended crown of the next wide bed, and continue it in like manner until the line for a new water-furrow is again touched somewhere. The narrow strip left between the two new beds should then be ploughed deeply, "out-and-out," throwing the slices alternately to each bed, and closing with a furrow which will be easily sunk full six inches lower than the old alley in the same place. Still the new bed would be badly shaped, owing to the four closed old water-furrows not being enough filled; and moreover it would be generally too low, compared to its width. Hence a second ploughing would be necessary immediately, or before any heavy rain. The first furrows of this should be run as before, except that instead of meeting on the crowns of the beds, (where there would be already a list sufficiently high,) a width of about two feet on the crowns might be omitted, and the first slices thrown no closer than to the edges of that strip. When the plough again reaches the water-furrow, it will have, by the gathering of so wide a bed, more room than before, to sink the new water-furrow, deeper, and also to clean it out well. These two ploughings, if well executed, and followed by a harrowing, would leave the surface of the bed tolerably well graduated, and gently sloping from the crown to shoulder; and the water-furrows at least 9 inches deeper than the old ones; and not only deeper, but generally sunk into the clay sub-soil, so as to convey the water off through a close and impervious pipe, as it may be called, instead of over open and loose absorbent soil. The mere consideration of the difference between the wide and the narrow beds, and the five small and shallow draining furrows of the former, and the broad and deep one of the latter, would show that the latter is better for drainage. Every such water-furrow is, in fact, a ditch, and a capacious and excellent one; but which is made and kept open by the plough, and furnishes no impediment to the crossing of animals, or of half-loaded carts. The fully loaded should be drawn along the bed, and would have a far better road than on narrow beds.

Grips or cross-drains would still be needed, but not in half the present number; because the now deeper water-furrows would keep any shallow standing water fully nine inches lower than formerly, and therefore less, if at all hurtful. But wherever necessary to be made, the grips should now be increased in depth, of course, in proportion to the new water-furrows, from which they are to draw the excess of water.

The wide beds are never to be reversed entirely; that is, the water-furrow must always be kept in the same place, and made as deep, and as clean, as ploughing can effect. For one or two crops, or ploughings, after the first, it may be best to throw the slices still towards the crown of the bed, so as to raise it higher. But if so continued, the bed would soon become too high, and the top either too round, or angular. This is easy to prevent. If it is desired to depress the crown of the bed, but yet to raise the sides midway between the crowns and water-furrows, let the middle and higher strips of the bed be ploughed "out-and-out," like a "land" in common flush ploughing, and without caring to preserve any precise outlines.

When the middles of two beds are thus ploughed down, or reversed, then the portion between them will be also broken up, throwing the slices "out-and-out" and of course up the sides of the bed, until closing with the last furrow accurately in the water-furrow. If the whole surface of the bed should have been so raised by previous ploughing, as to require being flattened, then the first two or three furrows should be run in the water-furrow, so as merely to deepen and clean it, throwing the slices neatly up to the shoulder, or edge of the bed. This being done in two adjacent water-furrows, the intermediate space should be cloven, or reversed; that is, ploughed downward. In this case the lists, or meeting slices, will be at the shoulders of the beds, and the operation leaves the beds in beautiful form, and good order. In any mode of cleaving down the bed, the closing and deepest furrow is always on the crown, which being before the highest, prevents there being made too much depression. After running the harrow over, the mark of that furrow will scarcely be visible.

The corn-rows on these wide beds, are easily and accurately laid off. The ploughman will first run a furrow, as near as his eye will fix, at 3 feet from the middle of the water-furrow; and then another, in the same manner, on the other side of the bed. The intervening space he then splits, by a row on the middle of the bed, and then again splits the two side spaces. This will give 5 corn-rows on each bed, with equal intervals, except the water-furrow interval being about a foot wider than the others. This will be ploughed open by mould-board ploughs, and thus left deep and clean, at the last working; but this at other times, and the bed intervals always, may be tilled merely by cultivators, or any similarly operating implements, and with as little labor as on land tended entirely level. When small grain is sown, the seedsman takes a bed at two casts, and throws from the water-furrow always, unless he sows twice over the same ground. Thus, though two feet width in the middle of the water-furrow may be considered as given up, and lost to tillage, and direct product, still there is much saving of labor, of seed, and of crop, wasted before in five times as many water-furrows.

This plan I substituted for narrow beds, and to my entire satisfaction, on low-grounds entirely different from, and far less suitable, than those of Gloucester. The greater and peculiar fitness of the latter is found in the circumstances of the absence of all flooding, and surface spring-water, the great depth of soil, and the impervious texture of the sub-soil.

The plan of narrow beds being here universal, and also the opinion that such are absolutely necessary to keep the land as much as possible free of water, the fields furnished no subjects for comparison; except between land on which the operation was executed either well, or very imperfectly. In the latter case, as before observed, the water-furrows are made receptacles and retainers of water, instead of dischargers; and the land is as much affected and injured by water, though not so regularly, as if it had been ploughed flush, and designed for flat culture. But even where the beds had been well shaped, and the water-furrows as well opened into cross-grips as can be hoped for in extended culture, wherever the sub-soil was retentive, and no plainly visible descent in the direction of the beds, and whether on land in wheat, or in corn, there were numerous evidences to the eye that the land had suffered by the water in the water-furrows or alleys. It cannot be otherwise on such level land, and under the generally existing circumstances. On such land, and so shaped by ploughing, the water-furrows, which receive so much water, must necessarily be too wet through winter, and until late in the spring. But these excessively wet streaks, each say a foot wide, are not more than nine inches below the perpendicular height of the crowns of the beds, and only two feet distant from them, and generally in the same absorbent soil. Under these circumstances, it is obvious, that if any water be in the water-furrows, and whether standing, or flowing off very slowly, the absorbent higher soil of the beds must be sucking up the moisture like a sponge, and must be thereby injuriously affected. While such a contest is going on, in the spring, between the water in the water-furrows, and the drying sun and air, much of the land prepared for corn has a superficially dry streak, varying from one to three feet in width on the middle of each bed, and which may be perhaps mellow and in fine order; while the sides of every bed, as well as the water-furrows, are still too wet to plough, or for any operation of seeding or tillage. Of course nothing can be done on such narrow streaks, until all the space is dry enough. A similar effect in unequal drying is found also on the wide beds. But there, instead of impeding, it forwards the opportunities for preparation and tillage. In winter, or early spring, the middle of the bed, to the width of from eight to twenty feet, may be abundantly dry for ploughing, while the lower parts are still much too wet; and the water, perhaps, standing in every water-furrow. On these middles, the ploughing may go on with nearly as much convenience as in the ploughing of alternate lands on a flat surface; and thus half the field, or more, may be ploughed well, before returning to take the lower parts as they become dry. On this plan, it is essential that the water-furrows be kept clean, deep, and always in their original positions; but so this is done, the remainder of the bed may be ploughed flush, and in any manner that such and other circumstances may render most convenient or desirable. The extreme outlets of the water-furrows into ditches, being few in number (compared to narrow bedding,) and never changed, may be deeply and neatly shaped by the spade; and will seldom need to be repaired; and therefore are always ready to operate. The reversing of narrow beds destroys the old outlets, and requires immediately a very troublesome operation in opening new ones by hand, which is to be repeated every time the field is broken up; and until the new outlets are so made, the new ploughing has served to make the surface basin-shaped, and suited to retain, instead of venting, all the surplus water that may fall on it.

The system of draining in the low-grounds of Gloucester is entirely of the surface, and almost entirely to guard against rain-water. Every acre needs surface-draining, and is, for that purpose, thrown into beds and water-furrows, and whenever necessary, with shallow cross-grips, and deeper ditches for continually flowing, though very feebly supplied streams. But no inundating streams affect the land, and no superficial springs have to be intercepted, except along the foot of the hills, at the junction of the high and low land. Being so much secured from both these causes of wetness, which are such great evils elsewhere, the farmers here, who do not border on the highlands, have directed their operations exclusively to draining the surface, and seem to consider nothing else as wanting. My objections to their plan have been urged at length, in the foregoing remarks on bedding. But even if their plan of surface-draining were perfect, and though the land is in a great degree secured from subterraneous and spring water, still I think that the land would be much benefited by deeper ditching. Though there is scarcely a spring which rises to, and flows off at the surface, still, as before stated, wells every where reach veins of springs at only a few feet below the surface; the depths of which vary from $2\frac{1}{2}$ feet on the shallowest black, to 6, or at most 8 feet, on the deepest gray land. As the water, and a continued supply, may thus be found in every spot, it may be inferred that it is under the whole of the land. If the whole of the few feet of the earth, lying above the marl and the springs, were of an absorbent and pervious texture, there is no question but that the underground spring water, having no low and sufficient outlets, would be continually rising by the absorption of the soil, and would affect the surface injuriously. This rising of the water may be, and probably is, generally prevented here by the almost universal substratum of close and tenacious clay, which serves as a shield against the subterraneous water. But still, the absorption must be injurious, wherever the sub-soil is at all open, in fissures, or otherwise; and this I infer must be the case to some extent under most of the black soil. It is therefore probable that if the ditches, which are now seldom more than $2\frac{1}{2}$ feet deep, were sunk considerably deeper, they would cut into, and discharge at the lower level, much spring water, which now, though never visible, and its operation not even suspected, is slowly but continually rising into and injuring the land, and still more the crops. These remarks apply to ditches on all the low-grounds. But besides, along the base of the hill where ditches are now always kept to cut off the little spring water that is visible, it is likely that deeper ditches would serve to cut off a much greater quantity, which now flows in a level so low as not to be visible, or even suspected. Experiment could easily settle these questionable points.

My examination of the Gloucester lands, and a small part of Matthews, was commenced on my arrival on the 11th of May, and ended five days afterwards. Even this short time, which at best permitted but a superficial view, was made shorter, (in more senses than one,) by the urgent claims made on my time by the hospitable attentions of gentlemen to whom before I was personally unknown, and whose kind invitations and attentions there was no resisting. The hospitality of Gloucester has long been celebrated: and, as generally in former times through lower Virginia, is carried to an injurious and blameable extent; which however is now a fault in but few other places, because both the land and the owners are now too much impoverished to continue the exercise of old Virginian hospitality. That Gloucester is yet able to do so, and that so many of the land-holders are still rich, or in easy circumstances, is only to be accounted for by the general fertility of the land which they have to cultivate. But though, to a visiter and stranger, there is every thing to be gratified with, in the refined manners and social habits which prevail here, and though I had especial reason to be thankful for the kindest and most flattering attentions, still these were so many impediments to my progress through the county, and still greater to my leaving it. The Gloucester people welcome the coming, and feast the staying, but do not "speed the parting guest." Being fore-warned of these kindly-meant restraints, I tried at first to beg off from dinner parties and visits upon appointment: but with so little effect, that I soon found it necessary to cease opposition, and was scarcely a free agent during my stay in the county. But in other respects, every aid was given to my movements and observations, when permitted to be so engaged; and I was carried either through, or close by and in full view of, nearly all the farms from Severn to North river.

The only part of the low-ground district which I did not see, was the part called Guinea, near the lower part of York river. This is very low land; and in that respect very like that of Matthews. It is settled exclusively by a number of poor people, who live more by fishing than by tillage. The land, though rich, and firm, is so low as to be covered by the highest gust-tides, and therefore is the less safe, and productive. I saw such very low lands, which had sometimes been swept over, and the growing crops destroyed, by salt water, on the farms of J. Sinclair, esq. in Gloucester, and of Wm. H. Roy, esq. in Matthews. On the lowest of these lands at all fit for tillage, cotton is the safest crop. Salt is evidently a specific manure for that plant; as lime is for wheat, and gypsum for clover; and of course, must always be furnished, to bring the crop to the greatest perfection.

On North river lies what was the Toddsbury estate, formerly belonging to the late Philip Tabb, who was celebrated as one of the best managers and cultivators in lower Virginia, and one of the earliest who had any pretension to be considered a very good farmer. The estate is now cut up into a number of different properties, and the general condition, taken together, has fallen far below its former neat order and productive state. But the beauty of the old mansion and its location, are still striking, even among so many adjacent beautiful places, in better repair, or of more modern construction. The half of the estate owned by Capt. Tabb, a son of the former proprietor, is however in progress to a much higher state of improvement, by his use of marl, with which his father never even made an experiment, though it is on the land in great quantity, and of very rich quality. This is one of the most striking proofs of the universal ignorance among the best, as well as the worst farmers, not many years ago, of the value of this manure, and of the natural constitution, and the wants of soils, on which that value depends. But even the total neglect of marl by Mr. Tabb is not such strong evidence of this ignorance, as the contemptuous manner in which it is spoken of by another still more distinguished farmer and improver, John Taylor of Caroline; who gives his opinion in his 'Arator,' that if marl were worth using as manure, it could hardly be supposed that the Creator would have buried it so deeply in the earth. However, even this curious *à priori* argument against the value of the marl, has no ground to rest on in Gloucester.

From what I could hear, the high and well deserved reputation of Philip Tabb as a farmer, was founded upon his uncommon forecast, and excellent judgment, as a crop raiser, and his neat, admirable, and successful execution in cultivation, and in the management of whatever he undertook; and not upon his improvement of the fertility of the soil; although he did much, for his time, in applying putrescent manures. Upon soil so productive and so durable as his, good drainage, good cultivation, and general judicious and provident arrangement and management, were all that were necessary to render his farming profitable, and to maintain, and even for a long time to increase, the producing power of his land. But his farming, and his views, would not have served to make poor land rich, nor to have maintained an increased production on a soil less durable than that of his fine farm.

There was another former resident and cultivator of Gloucester, of whom I tried in vain to collect some information. This was Clayton, the learned botanical cultivator and author. Some remains of his garden were still visible a few years ago.

The seat of Warner Taliaferro, esq., is one of the most beautiful situations (where all are beautiful,) on North river. Like all the others, the surface of the grounds around the houses does not appear to be more than four feet higher than the adjacent water, at ordinary high tide; and as far as the sight can stretch over the lands of Matthews county, on the opposite side of the river, there is no greater elevation. The neighborhood here, (and it is so in a high degree throughout the county,) is delightful. Mr. Taliaferro told me that the houses of twelve of his neighbors, all resident proprietors of farms, were within three miles of his own; and I believe that every one is within a hundred yards, or less, of the edge of navigable water. The farms of this neighborhood were long ago estimated by old Mr. Philip Tabb as worth £10 the acre, ($33.33,) and that price has been generally maintained. Under peculiar circumstances, some have been sold for not half that price. Half the Elmington tract, 500 acres, without a house, or any thing but the land, was bought two or three years ago by Warner Taliaferro, esq. at $30 the acre, in cash, and at private sale. This may be therefore deemed to be the fair price of land alone.

A few minutes' passage, in a beautiful sailing boat, carried us across from the last-mentioned residence to that of Wm. H. Roy, esq. in Matthews. This farm, and the adjoining one, belonging to Dr. Tabb, were made the limit of my excursion. But so uniformly low and level are the lands of Matthews, that the small space which I saw, furnished, as I was told, a fair and sufficient specimen of the natural features of almost the whole county. But not so as to improvement and product; for both of which, these two farms stand much higher than the county in general, These are principally corn farms; as is the case through the whole county, as wheat is considered comparatively unproductive. But this is not caused by the too great sandiness of the soil, nor by wetness. The soil is a loam of medium texture, and though lying so low, is drier than most of the somewhat higher lands of Gloucester. The lands of Matthews were originally covered by a fine growth of white oak-trees, which would be sufficient to prove that the soil is not too light for good wheat. Until the woods were mostly cleared, the people were more engaged in cutting timber for sale, and in ship-building, than in cultivation; but recently, as the former pursuits have been necessarily abandoned, farming has greatly improved, in manner and in product.

Mr. Roy's farm has been improved, from a former very poor state, to a present product of corn varying in different fields from 5 to 7 bbls. per acre. Of course, I infer that the soil was originally good and productive, however much impoverished afterwards. The marl stratum extends also under his land; but is there reduced to a thickness of only about 18 inches, so that its digging can scarcely be profitable. The great improvement made on this farm is owing to the very large quantities of farm-yard and other putrescent manures made and applied; and which now extend over much the greater part of the field for corn in a three-shift rotation. Leaves from pine woods, in quantity, as well as all the offal of the crops, are used as litter; and through all summer, as well as winter, for littering standing cattle and hog-pens. No waste or other evil is found, as I had feared, from too rapid fermentation during summer.

I was surprised to find that the old-fashioned three several hand-hoeings, (or weedings, as called,) of corn, were still approved and practised on Mr. Roy's farm. But as I hope to receive from his own pen a more particular account of his farming, I shall present no more of my own hasty and imperfect observations.

Looking from the shore near Mr. Roy's house towards the Chesapeake, there is nothing but water and sky to bound the prospect; as it is a straight course through the capes of Virginia on to the ocean. It was a clear and bright morning, with a gentle wind from the east, which is the state of weather favorable to the optical illusion called "looming," and which I soon witnessed in a remarkable degree. Before suspecting the effect produced, or thinking of it, though not entirely inexperienced, I saw, towards the sea, at such apparent distance as to be not distinct except in shade and in outlines, a very high and large object, nearly square in form. Had I not known that no such thing existed, I should have guessed it to be a castle, or some other enormously large dark building, at more than 20 miles distance; and, as the nearest to such an appearance that any real object could present, I supposed it to be really a thick cluster of very tall pines, on some low island, or point, made very conspicuous at so great a distance by being seen against the clear sky beyond. Upon asking what the object was, I was told that it was a "ship's-head bunch," which is a little brush fastened down by a few low stakes, and which is made as a baiting place for angling for that kind of fish. The actual height above the water was not three feet, and the distance to the bunch was not exceeding three miles. The deception of the sight was not removed, and scarcely lessened, by being informed of the true size and distance; though doubtless those who are accustomed to the phenomenon, learn to judge much better than strangers, and therefore cannot be so much deceived. The cause of the deception is the peculiar state of the atmosphere, which makes a near object appear to be very distant; and as the angle, from the eye of the observer formed by lines to the opposite outlines of the object, continues to be determined by its true distance, the supposed size is just what the extension of those lines would inclose, when at the supposed great distance of the object. As we rode along, another equally large and equally deceptious object came in view. It was nothing larger than a "blind," made for baiting and shooting wild-ducks.

The roads in Matthews are the best in the world. This is owing to the almost perfect level of the surface, the absence of all streams, or other water, and to the firm, yet sufficiently open texture of the soil. Every road has good ditches on each side, which serve not only to prevent water affecting it, but also furnish earth to raise slightly the middle of the road.

The whole county of Matthews is so well furnished with tide-water rivers, and inlets, that it is believed that not a farmer in the county is more than three miles from navigable water, and most of them not one mile. Yet with all this, the county is remarkably exempt from the bilious diseases which are supposed to belong to the low country, and especially to the low borders of tide-water. The explanation is found in this fact—and it would be worth millions of property, and thousands of lives, to the country in general, if properly applied —that there is not one mill-pond in the county. One pond-mill only is on the dividing line between Gloucester and Matthews, which, as usual, secures its annual snug little harvest of disease and death; but beyond its influence, there exists that state of health, and its accompaniments of physical power, energy, and capacity for enjoyment, so as to prove clearly to any reasonable and thinking people, that not one mill-pond (of the usual variable height of water,) should be suffered to remain in all the lower and middle parts of Virginia. But the subject is too copious to treat here, and too important to be neglected; and therefore I will present these facts and my commentary thereon at another time. I will merely observe here that the uncommon exemption from autumnal diseases which are the fruit of malaria, on the low-grounds of Gloucester, in which respect that region comes next to Matthews, and from mill-ponds, the sources of these diseases, is a blessing which alone gives value to their fertile soil, productive and convenient waters, and refined and delightful society. Tide-mills and wind-mills are used in Matthews; and also, but to a less extent, in Gloucester; as most of the low-ground proprietors there are also not far distant from some pond-mill on the highlands, of which the owner risks poisoning his own family, and certainly brings disease or death to some of his neighbors, to gain a few hundred bushels of toll-corn, and that at an expense often exceeding its value. However, I cannot blame mill-owners for availing of the profit conferred on them by law, by infecting and killing their neighbors, (when it is indeed a profit,)—nor would I propose, as a general measure, to deprive them of any such existing advantage, except for full pecuniary, or other sufficient compensation, to be made in return. But I *do* blame the legislative body, which permits the continuance and increase of these enormous and wide-spread evils—and also the blind and besotted carelessness and contentment of the people, who suffer the heaviest of these inflictions, and who will neither learn the cause, nor seek for a remedy. To this subject I will return—and again and again, while there remains any hope of awakening proper action.

From each of the rivers of Gloucester, there is a vessel which runs every week, to and from Norfolk; and there is one also which goes as regularly to and from Baltimore. These packets belong to a number of the farmers of the neighborhood, and are intended, and effect the object, to carry their products to market, and bring back their purchased commodities, in the most convenient and cheap manner. The captain of the vessel is not only the carrier of the articles, but the general agent and salesman of all the shippers: and in this manner the trouble and expense of a Gloucester farmer, in sending any surplus products to market, are not as great as if he lived only a mile or two from the town to which they are sent. This is another great source of convenience and profit to this region so favored in its position; and conduces to the economizing and selling of many small surplus products, which would otherwise be wasted.

The productive value of the land in the Gloucester low-grounds, and there being almost none which is not fit for tillage, when cleared and drained, have caused clearings to be very general; and the scarcity of wood, both for fuel and fencing, is one of the greatest inconveniences suffered by the farmers. Pit-coal is already in regular use as fuel in some houses on North river. For fencing, chestnut, which fortunately was a plentiful growth of the high-lands, has been recently the main reliance for the low-ground farms, even at 7 or 8 miles distance by land-carriage, and the timber purchased at a high price. As rails of this timber are almost secure from rotting, when not in contact with the earth, these costly fences are still cheap improvements. But the chestnut timber is now very scarce, and can no longer be counted on as a sufficient source of supply. Ditches and banks, for which the land is so admirably adapted, will probably hereafter be made to serve for inclosures; and in aid of this important object, deep and wide ditches will have an important value, in addition to the several others already mentioned.

All the low-ground farmers are now suffering greatly by the depredations of cut-worms and bud-worms, or wire-worms, on the young corn. Some have been compelled to plough up, and plant again, many acres of their fields; and the land not so treated, in many cases, requires to have two-thirds of the places replanted; and the loss, to the future product, as well as in present labor, is enormous, this spring, throughout the low-grounds. The great number of these worms, I should have supposed, might be sufficiently accounted for in the usual practice of breaking up the land for corn, late in winter, or in spring. On clover-sod, especially, so treated, elsewhere, great injury from worms would be counted on. But here, there must be some other cause still more favoring their depredations; as I was told of parts of fields having been ploughed very early in winter, and on which, notwithstanding, the corn is as much injured as on much later ploughing. This has been an uncommonly cold and backward spring, and these lands are always kept colder in spring, as before stated, by the prevailing easterly winds. Until the 17th of May, the last day of my stay in the county, there was not one in which fires were not necessary for comfort. The cold, by retarding the growth of young corn, keeps it longer at the state in which the worms prey on and destroy the plants; and hence, the peculiar injury sustained this spring, and indeed, every spring, compared to warmer lands. But though the cold directly produced by the exposure to easterly winds, is an evil which cannot be avoided, still the ravages of insects would be doubtless much lessened by earlier ploughing, and still more by the more effectual drainage of the land. This last would not only permit the land to be ploughed earlier, and in better condition, but probably would lessen the coldness of the air, by avoiding the evaporation of so much excess of moisture as is now in the soil. The effect of evaporation in producing cold is a well known chemical fact; and there is probably more evaporation from one acre of ploughed and moist land, than from ten times the space of water. Thus, good drainage would serve not only to increase the productiveness of the soil, directly, but also indirectly, by forwarding and improving the ploughing, raising the temperature of the air, and by both means, helping to restrain the annual ravages of noxious insects.

One considerable off-set to the numerous advantages and delights of a residence on the low-grounds, is the bad quality of the drinking water. It was to me, however, less objectionable than I would have expected; though my sense of taste is not sufficiently acute to render me a proper judge of the quality of water. The wells almost always reach water in the marl, from which the foreign flavor is communicated. In the very few cases in which water is reached by wells before touching the bed of marl, it is said that it is very good. If, by boring, and putting down closely connected pipes, water should be drawn from beneath the bed of marl, (which has not yet been pierced through,) I think it very probable that it would be found pure and excellent. The water which percolates through marl, and supplies wells sunk therein, is bad in every known locality. On a very high and hilly farm, my residence some years ago, which was under-laid by marl throughout, the many springs, within convenient distance of the house, all furnished bad water. A well was commenced, though with but little expectation of obtaining different and better water, as these springs were nearly all around; and still less hope remained, as no water was found before penetrating the marl. Luckily this bed did not furnish so much water as to prevent continuing to dig, and getting quite through the marl to a soft sand below, from which rose an abundant supply of water, as pure and as cold as any known east of the falls of our rivers. The water rose to and stood at the height of 13 feet above the level where it was tapped. This one known result as well as theoretical opinions, would encourage me were I a resident on these low-grounds, to bore for pure water through the marl, if it should not prove to be too deep.

A young lady who had spent much of her childhood in this part of the country, once told me that the ice-houses were the most ornamental buildings in Gloucester; and though, for want of explanation, I could not imagine a ground for this opinion, I readily admitted its force as soon as the subjects came under my own view. As water lies so near the surface, and the soil is too close to permit water to sink through it, it is obvious that ice-houses cannot be made in pits, below the surface, as usual in the higher country. Hence, they are necessarily constructed on and above the surface of the ground. One plan of construction is general. A circular brick wall forms the body of the building, which of course is a regular cylinder, surmounted by a roof, which is, in shape, a flattened cone, the base of which is so wide as to form eaves projecting unusually far without the body of house. A mound of earth, circular at the base, regularly sloping as it rises, is thrown up all around and against the body, and conceals it to within two or three feet of the eaves of the roof. The mound of earth becomes covered with green turf. The summit of the conical roof is surmounted, in some cases, by a spire, in others by a ball, or small cupola. Altogether, in plan, proportions, and neat execution, these ice-houses are very pleasing to the eye, and add much to the beauty of the grounds around every mansion on the low-grounds.

[TO BE CONTINUED.]

LAW OF NEW-YORK IN REGARD TO TRESPASSING STOCK AND DIVISION FENCES.

To the Editor of the Farmers' Register.

* * * *

I have a friend who lives in the western part of the state of New York, now on a visit to me here, and in conversing with him on agricultural and other subjects, I have derived many useful facts—one of them I will detail to you, because it is of striking utility in my view, and on a subject upon which you have long interested yourself.

He informs me, that in the state of New York, the laws require every farmer to have such enclosures as will keep his own stock in—if he has none, he needs no enclosure, except on public highways. If then the stock of our neighbor encroaches on another, the one encroached on sends them to the nearest pound-master of the township, (and there are several in each,) who pounds them, and notifies the public of the fact, describing them, that the owner may come forward and claim them. The person trespassed upon then calls together three respectable, disinterested neighbors, who assess the amount of damage he has sustained by such intrusion, which the owner has to pay, together with all expenses of the pounder, &c. before the stock will be surrendered up to him; and in default of which, they are sold to make it good, and the surplus, if any, refunded to the owner.

This I consider an equitable and admirable regulation, and if adopted in this state, would save much trouble and discontent among neighbors. He also informs me of another equally just and necessary regulation. In all cases of *division fences* between neighbors, *each party* is *bound* to share equally the expense of such an enclosure as is usual in the vicinity, and in case of default of either, the amount is recoverable before a magistrate.

This strikes me as a most wise provision; for occasionally you meet with a selfish, perverse man, who will contribute nothing to such an enclosure, although equally benefited, because he knows the other party would sooner erect the *entire* fence, than be, without it, liable to constant annoyance: and in such cases this provision would apply most happily.

I have ventured, my dear sir, to give you these ideas, thinking you might choose to embody them in some publication of your own on the subject, if thought worth it; but not to be published as coming from me.

[The condition required by our correspondent in his last sentence, is complied with by our withholding his signature.—Ed. Far. Reg.]

For the Farmers' Register.

MONTHLY COMMERCIAL REPORT.

Markets have undergone little variation this month. Tobacco continues in good demand at $4 to $11 per 100 lbs., including all sorts except fancy qualities for manufacturing. The quantity inspected greatly exceeds that of last year to same date, the price being an inducement to get it to market.

Cotton commands (in Petersburg) $8\frac{1}{2}$ to $9\frac{1}{2}$ cents, according to quality. The receipts at the various ports of shipment in the United States, are about 1,550,000 bales against 1,230,000 at same time last year. The demand for cotton goods in England being very dull, this excess of the raw material must cause prices to continue low for some time.

The growing crop of wheat is reported to look fine generally; but in some parts of the country, the insect called chinch-bug has attacked it and done considerable injury.

Internal exchanges are improving, but the difference between some places is still very great; as for instance, between New York and Natchez, 20 per cent., Mobile 12, New Orleans 8, Charleston 5, and Virginia 4. Bills on London are 10 per cent. premium in Richmond.

Since the resumption of specie payments in New York, there is little or no pressure on the money market, and stocks generally have advanced. The importations of specie have continued to a very large amount.

The last legislature of New York authorised the establishment of private banks to an unlimited extent. Those persons who engage in the business, are required to deposite with the comptroller of the state, the amount of capital on which they wish to operate, in such United States or state stocks bearing 5 per cent. interest, as he shall approve, and can receive from him an equal amount in bank notes properly countersigned, so that the issues of notes will be limited to the amount of security thus deposited, and made responsible for their redemption.

Should this system be found to work well, as is confidently believed it will, the example will doubtless be followed by other states, and it may introduce a system of banking less liable to abuse than that which now exists.

The facilities of communication on the main line of rail roads have been increased this month by the opening of one between Richmond and Petersburg, and by the completion of the bridge over the Roanoke at Gaston, and of a portion of the rail road south of that place. X.

THE FARMERS' REGISTER.

Vol. VI. JULY 1, 1838. No. 4.

EDMUND RUFFIN, EDITOR AND PROPRIETOR.

REMARKS ON THE SOILS AND AGRICULTURE OF GLOUCESTER COUNTY.

By the Editor.

[Continued from page 178 of this volume.]

One of the most interesting objects which I visited in Gloucester, was Rosewell, the residence of the distinguished patriot John Page, Governor of Virginia, and of his family preceding and succeeding him. The house is situated on the border of York river, and commands an extensive view over the deep blue waters and the clean white beach of that most beautiful of all our wide waters. The land, though said to be good, and productive, as a farm, considering its long neglected state, presented nothing which attracted my notice, or diverted attention from the ancient and venerable building, to see which, was the object of my visit. The walls of the mansion-house form a cube of 60 feet. The roof is flat and covered with lead, except the central and more elevated parts, which are so low, however, as to be hidden from the outer view by the surrounding parapet wall of about 3 or 4 feet high. The style of building is plain and simple. Though the materials were of the best kind, and the construction and decoration such as must have been very costly, still the whole appearance is as plain, as if embellishment and display were not only not sought, but despised by the builder. It is said that the massive walls contain about a million of bricks; most of which, according to the fashion of old times, were brought from England. The interior walls of all but the upper apartments are wainscoted with black-walnut to the ceiling, and the balustrade of the great staircase is of mahogany, richly carved. All appears simple and severe, and yet grand, and nothing seems designed for ornament, or ostentation. The chimneys, which so much disfigure all modern buildings, are here so massive that they seem more like the turrets of the ancient structures of the feudal age; and the resemblance is further increased by two small circular erections in the roof; one of which is the upper end of the flight of stairs, and the other a sort of observatory, where the extensive prospect and refreshing sea-breeze might be enjoyed in the greatest perfection. Altogether, the Rosewell house bears not a very faint resemblance to an ancient baronial castle; and, except the ivy-capped ruins of the old Jamestown church, (under whose shade these lines are pencilled,) I have never seen any structure so venerable in its form, and in its progress to decay. Both these buildings, and some others on hallowed spots, ought to be made public property, by purchase, and preserved, both from decay, and from any repairs except such as might be necessary to preserve the present appearance. Rosewell house overlooks a wide expanse, rich and beautiful by nature, and now deformed and impoverished by both the abuse and neglect of man; and it stands alone, in solemn grandeur, though undervalued and in decay, an emblem of the old aristocracy of Virginia, of which, with all its virtues and vices, its wealth, refinement, and wastefulness, there is now so little left, and that little fast fading away.

But though in comparison to its former state, the Rosewell house may now be considered in a state of dilapidation, still, as a residence, for the present, it has not greatly suffered by decay. The principal injury sustained, and which threatens future destruction to the interior of the building, if not soon guarded against, is the partial sinking of the ceiling of the great hall, on the lower floor, and which takes away the support of the second and third floors above the place of failure. A timely support by a central pillar would prevent the further progress of this injury. The present owner, and recent purchaser of this estate, Mr. Booth, besides the convenience of keeping his own residence in comfortable repair, doubtless feels the inclination to preserve this noble monument of ancient times. But the expense necessary for this purpose would exceed the cost and present valuation of the whole estate; and there are few individuals, in this utilitarian age, who would be willing to bear this burden. The estate, containing more than 1000 acres of land, was sold at auction a few years ago, for $11,000; and was bought by Mr. Booth, for a small advance on that price. This is not more than the bricks of the mansion house alone would cost; and the probable future destiny of this building, will be, after falling into complete decay, to be demolished, for the use of the remaining materials. Such has already been the end of another building, not far distant, which not many years ago was not less an interesting object as a venerable ruin, than hallowed by historical events. This was the once splendid mansion of the old Secretary Nelson, uncle to the patriotic Governor Nelson, in Yorktown, which in the beginning of the siege was the quarters of Lord Cornwallis and his principal officers. The walls were perforated in many places by the cannon balls from the batteries of the besiegers; which in part were so directed by the special orders of Governor Nelson, then commanding the Virginia militia, and who dealt the same measure to his own dwelling-house, though that was better protected by distance, and its more humble size; and it still stands, the best remaining building in the decayed and almost deserted village of Yorktown. Secretary Nelson was then confined by disease to his house, which stood in an angle of the British interior intrenchment, and directly in the most important line of defence, and attack, and therefore peculiarly exposed. His three sons, as well as his nephew the governor, were in arms among the besiegers; and he was at last permitted to take refuge in the American camp, on a flag of truce being sent for that purpose by Washington, and borne by one of the Secretary's sons. Before his removal, one of his servants, in the same apartment with his master, and while speaking to him, was killed by a ball from the besiegers' cannon. Though the house was made a ruin by the fire of the American batteries during the siege, it long remained one of the objects of highest interest on this ground, which is altogether so interesting as the closing scene of the war of the American revolution; and twenty-seven years ago, when I first saw it, the greater part of the outer walls and three of the chimneys were still standing. All has since been demolished, merely for the use of the materials; and the site is distinguished only by a greater quantity of rubbish, scattered by the side of the British line of defence.

The present owner of Rosewell was not at home; but still I was obliged by the kind welcome which he had prepared for my expected visit. If it was not so much out of the way of travellers, I doubt not but that Rosewell would be considered an object of interest, which would probably expose the owner to many such intrusions as mine, and which would become, by their number, more annoying than welcome.

Gloucester-town, (which has not the semblance of a town,) lies immediately opposite Yorktown; and the former as well as the latter place was fortified by part of the British army under Cornwallis, and invested by a part of the American forces. The remains of four redoubts, which defended the point of land, still are seen, in quadrangular mounds of about 8 feet elevation; and these, like the intrenchments of both besieged and besiegers surrounding Yorktown on the opposite side of the river, and even the large holes in the ground which were made by exploding bomb-shells, will probably continue visible until Yorktown itself shall have reached the end of the decay and ruin to which it has long been making progress. Another redoubt, standing alone, is on the road, about a mile from Gloucester Point. This probably was an outpost of the investing force. The mound furnishes an agricultural lesson to those who maintain that any barren sub-soil, brought up by deep ploughing, will become fertilized by exposure. The sandy sub-soil, thrown up in erecting this work fifty-seven years ago, is still bare of vegetation.

The most valuable thing now in Yorktown, (supposing antiquities and historical memorials to be worth nothing,) is the body of rich marl which under-lies the town, and is exposed on the river side. It is perfectly dry, and of a texture more like very soft rock, than shell-marl or earth. It is in this that the artificial cavern was made which is called Cornwallis' cave, and which tradition tells was his lordship's quarters after Secretary Nelson's house was no longer habitable. But like most other traditionary accounts, the fact is disputed. When I first saw the cave, in my boyhood, it was entered by a doorway of small size, and consisted of a square apartment, from which another door led to a second room of smaller size. The walls and ceilings were shaped well and neatly; and the firmness of both showed that the excavation might be continued safely, to any extent, without any other props than walls of the marl itself. This quality, and its great richness, would make the bed valuable for shipping marl for sale; which has already been done, without the need of excavating, from a place a few miles lower down. But until within late years, I think it most probable that nobody in York county knew any thing of the composition or value of the earth in question; and still, judging from their works, but little value is yet attached by them to the use of the manure. When I last entered Cornwallis' cave, one of the apartments was nearly filled with fodder, and the other was converted to a hog-sty, which, in the darkness, I could not know by sight, but was soon informed, by the grunting and the stench, of the presence of the successor of Lord Cornwallis.

STATEMENT OF SUCCESSFUL FARMING, ON A SMALL SCALE, ON GLOUCESTER LOW-GROUND.

By the Editor.

The farm of Jefferson B. Sinclair was referred to in the preceding article (at page 181, No. 3,) and the more important of the peculiar circumstances, and qualities of the soil described generally. In addition to what is there stated, as part of a general sketch of the soils and agriculture of Gloucester, and to which I beg to refer, as prefatory to this statement, I will here report more particularly on the labors expended on, and profits derived from, the cultivation of the farm. The choice of this farm for more particular notice, is not directed by any of the considerations which might be supposed usually to operate; and whether it is well or ill-directed, it will at least be manifest to those best acquainted in the county, that the choice of the writer is not directed by considerations of self-interest, or by a desire to pay court to those enjoying high station, or exercising extensive influence. Mr. Sinclair, notwithstanding his considerable gains, is not yet one of the rich men of Gloucester, nor one who makes any pretension to fashionable, expensive, or "stylish" living; neither has his system, or general plan of farming, any thing commendable, nor is its execution of that neat and perfect kind to please the eye, and command admiration. He was quite a poor man, who, by unremitting industry and care, and by making good use of some of the peculiar advantages of his land, has greatly improved both his income and his farm, and who now shows very heavy crops, and derives large profits. Others, in the county, with greater advantages of spare capital, and more extended agricultural information, have performed operations in cultivating or improving their lands far more likely to attract and gratify the observer, and to command his applause. But the past and present circumstances of this farm will better serve to show, by example, the capacity for improvement and increased product of the land, and the profit which may be counted on to reward steady industry and economy. Whatever has been done here is the result of labor, almost alone, at first; and since, of labor united with the capital produced by the earlier bestowed labor.

This farm, as in the foregoing article stated, lies on the shore of Mobjack bay, and, with two or three adjacent farms, forms the "neck" or point between the mouths of Ware and Severn rivers. The greater part of the neck, as well as the greater part of Mr. Sinclair's arable part of it, is so little above the level of the sea, that it has been sometimes, though rarely, covered by storm or gust-tides. The greater part is probably not more than three feet above ordinary high tide.

The father of the present owner was a regular seaman, and in command of a vessel in the merchant service. He came from a very different kind of farming land, (near James river,) from this, which he settled on in the latter part of his life. No one could be more unfitted to manage the land, by his previous different pursuits, and want of knowledge; to which was added growing blindness, which soon become total. The management of the farm was necessarily left to the entire direction of the overseers; who, instead of extending cultivation over the waste but highly fertile wet land, actually retreated before the invasions of the tilled surface, by water on the lower, and by wire-grass on the drier parts, until nearly the whole had become unproductive and waste. It was in this state that the present owner received his portion, 13 years ago, without a house upon it, and with scarcely any moveable or working capital, except three negroes capable of aiding him by labor. I do not remember positively, but infer, from the great subsequent increase of slaves, that there were also young negro children; but these of course at first were sources of expense and not of income.

The land, then, exclusive of marsh subject to be covered by ordinary tides, was 433 acres. Since, two different adjoining pieces, of the best (chocolate) soil, but excessively worn and abused, have been added by purchase—the first at $12.25 and the second at $20 the acre. These purchases have increased the tract to 500 acres, or a little more. Of this about 150 acres are of the chocolate soil, lying on rich marl, rising so near the surface as often to be touched by deep ploughing; and 350 of gray land, of the ordinary kind of the most worn and reduced in the county—and some of which, even now, is very bare, and appears very mean.

Under all the existing disadvantages, it may be thought that with 433 acres of land, of which 75 were rich and of admirable soil, the owner was well furnished at least with *landed* capital. But this capital was dead, until it could be improved by labor, of which there was very little; or by money, of which there was none at all, until after it had been earned. In addition to the other necessary expenses, the mother of Mr. Sinclair had a life-interest in the land, which he bought for an annuity of $100; which annual charge is still paid. All the then dry and rich land was under the strong wire-grass sod, to the mastery of which the preceding indolent and careless management had yielded the land. The first thing to be done, was to attack and subdue this powerful enemy to cultivation; and without success in which, nothing of value could be effected on the land. The whole team in possession was a horse, a mule, and a pair of oxen; and it was necessary for all four to be hitched to one plough to break up the land under wire-grass. With this large and oddly combined team, and with a boy as driver to aid the ploughmen, no more than four of the five-feet beds could be ploughed in a day. Nevertheless, this slow labor was persevered in until it was rewarded by ultimate success. Now, the land is so free from wire-grass, that a farmer who had suffered from the pest elsewhere, would find it difficult to believe that this land had ever been so completely sodded with its growth. By the frequent cropping of the land, since the breaking up, much has been done for this result; and, as Mr. Sinclair thinks, much more by summer-fallowing (for wheat) at the time when the wire-grass was in bloom—which he considers as his only means for success, and one which may be relied on in general. It is a new and important suggestion. But I still doubt much whether that means, or any other, available as part of a proper rotation, would have been effectual on a more sandy soil, which is much more favorable to wire-grass than a clay loam, like this chocolate soil. The quantity of calcareous matter in this soil, and its fertility, were favorable enough to this growth to make it cover the land, almost exclusively. But it would have had a still greater degree of vigor, and vitality, if the soil had been also sandy. It is proper here to state, that Mr. Sinclair, when suffering most from this growth, visited Weyanoke, to see the very laborious operations of Mr. Fielding Lewis for restraining (for he could not eradicate,) this pest—which were described in the first number of the Farmers' Register. Having learned the whole practice, and paying implicit respect to the authority of Mr. Lewis as a farmer, and to his experience as a wire-grass farmer, Mr. Sinclair returned home and tried sufficiently the same tedious and costly labor, of digging out and removing the roots. But there was so little benefit found from the experiment, that he never repeated it. He therefore thinks that neither to this mode, nor to frequent tillage, but entirely to his ploughing when the grass was in blossom, is he indebted for the destruction of the growth.

The pair of oxen which composed half of the team of the plough used in the first breaking of the wire-grass land, at other times had to draw all the fuel for the family, rails for fencing, and also the materials for building the dwelling-house. They were 6 years old when bought, at $45; and after being regularly at work for about 6 years more, they were allowed to have a summer's grass, at rest, and were then sold, as beef, for $10 more than the pair cost at first.

The shelly land, which was formerly a wide-spread swamp and pond, the resort and shelter of wild-ducks, is now well drained, and part under heavy growths of wheat and clover, and the balance in fine and mellow tilth, under a young but promising growth of corn. The unusually perfect drainage of this very low surface, I have before ascribed to the open and loose layer of broken shells, which forms the under-stratum, and serves in effect as a complete under-draining of the whole surface soil.

The manuring with the natural compost, or mixture of calcareous and putrescent matter,) which every ditch furnishes, both when first dug, and whenever afterwards cleared out, has been quite extensive. Much manuring has also been done from the farm-yards, and otherwise by the dung of stock. There still remain to be availed of, and which have scarcely been commenced on, for want of labor, not only the rich and unmixed marl lying under the whole of the chocolate soil, and generally within a foot of the surface, (and which the gray land greatly needs as manure,) but also inexhaustible supplies of putrescent matter, in the "sea-ore," or sea-weeds flung by the waves upon the shores, and in pine-leaves from the low sea-pine land, which, though firm, is too low, and too much exposed to the tide, for safe tillage.

If the means for using them were not wanting, there are resources here for durably enriching every poor acre of the farm in two years. And much has certainly been done towards its fertilization, considering the existing obstacles; although much more remains to be done, and which, for the doing, promises sure and high profits.

What are known as salt-water pines, are the almost entire growth of the still lower land lying between the fields and the bay shore. These pines seemed, to my eye, to be the same kind as the common woods-pine, (short-leaved) of the higher country; but these appear more dwarfish and stinted, as if on a very unkind soil; and they are of remarkably slow growth compared to the pines of the poor upper country. A beneficial effect of this slow growth, is the large proportion of heart-wood, and the longer durability of fences made of this timber. It is thought that the salt drawn up in the growth of the trees conduces to the durability of the dead timber. It is certain that the sap-wood of these, or of any more perishable pines, is made more durable in fences, by having been first left covered in the salt tide-water for six months or more. This is a common practice in this part of the country; and the rails in the fences are so thickly stuck over with attached shells of barnacles, as to show the long continuance of their salt-water immersion.

The belt of pine-forest, though probably not so designed, must be of much benefit to the arable land, by sheltering the crops from the cold and violence of the east winds, coming from the Chesapeake and the Atlantic. The soil on which the pines grow, low as is its level, is of the gray kind; and though, like all the rest, under-laid by the great bed of marl, is sufficiently thick above it, and (judging by the growth) sufficiently acid and poor, to furnish the proper food for pines, unadulterated by the neutralizing quality of the subjacent calcareous earth. It is, however, a singular location for a pine-forest; and, like some other still stronger apparent contradictions, would cause many to doubt the doctrine of calcareous soil being incapable of sustaining pines, and some other common acid plants.

There has been no regular course of crops on this farm, nor any approach, in practice, to what would deserve the name of a rotation. The proprietor, being constrained, in a great measure, by the former foul state of the rich land, which demanded repeated hoed crops—and tempted to draw from it heavily, both by its power to produce, and his own need for the returns—the general course of cultivation has been irregular, severe, and also totally opposed to the established general rules of good husbandry. Still, circumstances well justified this departure from sound theoretical and general rules; and, on the whole, it has probably conduced much to the profit of the farm, and also to its general improvement; for quicker and greater profits served to furnish more labor for improvement, as well as for more effective tillage; for both of which so much labor was wanting. But the time and the circumstances have now arrived, which will make a more regular and meliorating rotation the most profitable here, as well as in most other situations.

Until about seven years ago, Mr. Sinclair had not sown clover, nor had he been induced to desire to commence its culture, from any witnessed prior trials of others in his county. His commencement was determined, not by design, but by accident, or rather by a ridiculous blunder. He had requested the captain of a northern vessel to bring him a peck of flax-seed. By a fortunate mistake of the captain, he brought, instead, as much clover-seed; which was sown, merely because on hand. The product, however, was so good as to induce the continuation and increase of the annual sowing, until the last amounted to 8½ bushels of seed, and the present clover crop covers 60 acres.

But though his clover-culture has been entirely satisfactory in products and in the conjectured clear profits, it has, as yet, furnished almost nothing to the scythe, either for green-food or for hay, nor as green or vegetable manure to the land—except for the latter, so far as may go the mere roots, and the little of the stalks remaining after grazing. Besides the grazing of other farm-stock, there is a large number of hogs fed on clover, from the time it is 6 inches high; and as I heard a neighbor of Mr. Sinclair's charge him with, in some jocular censures of his management, he does not even give his clover a chance to get into blossom. The hogs are not, however, turned upon the whole field, but upon a part separately inclosed by a temporary or moveable fence; and from that they are changed to another, and so on, so as for them to graze all the allotted space in succession.

If about 100 hogs are desired for annual slaughter, then 20 female pigs are left as breeders, and three or four male pigs. It is so arranged that all the pigs are littered in April or early in May, soon after the hogs have been all put upon the young clover. The births are easily thus timed, as the practice is to castrate all the boars soon after the sows are pregnant, and to fatten and kill them, and all the sows also that have had pigs once, the next winter. Thus there is an annual succession of very young breeders, male and female, and no hog ever remains to be as old as two years. Of course there are but the 20 sows, all pregnant, to feed, from killing time to the beginning of grazing on clover, after which, they have no other food, except the gleanings of the wheat and other small-grain-fields after harvest, until put up to fatten in autumn. For five years there had been killed from 75 to 108 hogs annually; not large, of course, but fat, and of good size for family bacon. The annual sales of pork add largely to the income of the farm. In 1835, the fresh pork sold brought $1200, and the weight of the hogs averaged 133 lbs.

Mr. Sinclair made an experiment last winter and spring with his winter-kept hogs, or breeders, which, so far as one experiment may be relied on, seems decisive against letting hogs run at large in woods and marshes, to aid in supporting themselves. In the beginning of winter, the hogs were divided into two parts, as nearly equal as possible, in numbers, sizes, and condition. Those of one division, were suffered to run at large, in the sea-pine woods, and having access to the close adjacent bay shore, and 300 acres of firm marsh; and received every morning, each, one ear of corn, and another at night; or, when shattered corn was used, as much morning and evening as was supposed to be equal to one ear to each hog for each meal. The hogs of the other division were confined to a well littered pen, in which was a close and dry house or shelter, which they could enter at pleasure, and be perfectly protected from wet and cold. These could get no food except what was given to them; and that was the same as was given to the others, that is, one ear of corn to each, twice a day. They probably helped their food somewhat from the litter of corn-stalks and wheat-straw, which I suppose were the kinds furnished in part or in whole. The result was, that in spring, when the clover was fit to receive them, the pen-fed hogs were in much the best condition. Some of the others, running at large, had actually died, and al lthat lived were poor and lousy.

Now it must be admitted that the want of precision in fixing the quantities of food given, (though *designed* to be equal, and supposed to be as nearly so as such mode of estimating permitted,) detracts much from the otherwise very important value of this experiment. Still, it can scarcely be supposed that one who is so careful, and so successful, in his general management of hogs, could have been much deceived in the details of this experiment, in which, and in the apparent result of which, he has entire confidence. It should be further considered, that if cooked, varied and mixed food, of roots and other vegetables, as well as grain, had been given to the confined hogs, that there is no question but their health and flesh would have been better sustained, at equal or less cost, than by corn alone.

The hogs are all of a cross of the "no-bone" breed upon the common kind; about half-blood of each, which is deemed preferable to the pure no-bone stock. The front edge of the cartilage with which hogs root into the ground, is trimmed off, which entirely stops their rooting.

Having heard the products of this farm last year (1837) spoken of as very considerable, by a neighbor of Mr. Sinclair's, I inquired of him particularly as to the amount made. The grain crops were as follows:

1621 bushels of wheat, made on 80 acres, which is at the rate of $20\frac{1}{4}$ bushels to the acre: sold at $1 65 the bushel, (and counting reserved seed at same,) amounted to -	$2674 65
600 barrels of corn, from 75 acres, or 8 barrels to the acre, (of which 300 barrels were sold,) say at $3 25 (I forgot to ask the actual price obtained,) -	1950 00
350 dollars worth of pork, lard, and bacon, were also sold; but as the hogs were partly fed on the corn above estimated, I will count half their product as due to the corn, and the other half to the clover, gleanings of wheat field, and the waste corn, not estimated above—which is, - - - - - -	175 00
The smaller articles of product were not noted; but the following, were supposed to be within the amounts actually sold:	
Butter - - - - - - -	90 00
50 lambs at $2 50 - - - -	125 00
13 grass mutton at $3 - - -	39 00
Whole value	$5053 65

This is exclusive of sundry smaller products sold, as poultry, &c. of which no estimate is made; and of large ones, which though consumed at home, are not less of value as products; as the fodder and other offal parts of corn and other crops. Also the wool and cotton, produced at home, and from which all the slaves are clothed, by spinning and weaving only in weather and times unfit for field labor. This usually very costly part of farm management (or its substitute, buying all the clothing,) is gotten over easily and cheaply; but the credit for this, as well as for much else of value in domestic economy, is entirely due to Mrs. Sinclair, whose aid has been throughout of very great importance in improving the income of the farm. This I may be excused for saying, as it is the report of her neighbors.

There were no calves sold for veal, last year, as usual, (all being kept to increase the stock,) which lessens the amount unfairly, as this is one of the usual products of the farm. The year before, 1836, 15 calves were sold, at $5 each.

Much the greater part of the above amount is composed of sums received for sales actually made; and the much smaller part, only, was of things consumed at home. The results will therefore appear more striking, if the net amount of actual sales is presented alone, as follows:

Deduct for seed, suppose 100 bushels of wheat, at $1 65, leaves for market - -	$2482 65
300 barrels of corn sold, (at price supposed) 3 25 - - - - -	975 00
Pork, bacon, and lard sold - -	350 00
Butter, lambs, and mutton, as stated above - - - - - -	254 00
	$4061 65

If it is further considered that there is nothing to be taken from this sum to buy clothing for the slaves, now increased, by purchase and births, to 40 in number, the net returns will appear still more important.

The laboring force on the farm is now that of 12 slaves. There are now 50 head of cattle, and 107 sheep.

In all things essential to product, or for improvement, the operations of Mr. Sinclair are well executed; but in things not essential, and in every thing having regard merely to appearance, it must be confessed that he is a very careless and slovenly farmer. Nevertheless, in most of these omissions, held so important by all *martinet* farmers, I doubt not that he has been justified, by the sure test of the amount of *net product*. Still, some very manifest exceptions are to be seen, in which neither economy nor convenience have been properly consulted.

To the Editor of the Farmers' Register.

TROPICAL FIBROUS-LEAVED PLANTS.

Washington, D. C., 8th May, 1838.

I have the pleasure to acknowledge the receipt of No. 2 of your periodical of the 1st inst., and hasten to send you some very small samples of foliaceous fibres, or substitutes for common flax and hemp, with the hope that they may excite your minute attention towards the articles and plates on the fibrous-leaved plants. Should you visit Washington during the present session of Congress, and examine the full specimens, now in the committee-room at the capitol, and soon to be in the agricultural department of the patent-office, I entertain the respectful hope, that you, in common with all intelligent gentlemen who have seen them and studied their history, would coincide with both committees in their estimate of the future importance of the fibrous-leaved plants, to all the worst soils between the Potomac and the Mississippi. Every member of the senate and of the house of representatives, who has visited the committee-room and given the specimens an examination of 5 to 10 minutes' duration, has expressed his sense of their high importance, and his approbation of the reports of the committees. But such visits have been so "few and far between," that it would require two or three years to elapse before the specimens would be seen by a majority of the members of the Congress, although the whole time necessary for a visit from either chamber would not exceed ten minutes. To enable you to form distinct ideas of the origin of the foliaceous fibres sent to you, I refer to plate 1, figs. A, B, C; and of the mode of separating them, to plate 2, figs. A1, A2, N and T. By a further reference to the printed articles in the latter part of the report of the house of representatives, under the heads of *agave sisalana*, *musa abaca*, and *bromelia pita*, a few brief notices of each will be seen.

In your editorial remarks, whose general correctness I acknowledge, there appear one or two statements apparently founded on misconceptions. For example, in speaking of the reports, you say, "but both of them are but second editions, revised, corrected and enlarged, of prior publications made in like manner by order of Congress." The fact is, that in the house report, there are but 26 or 28 pages to which that statement is applicable, and in the senate report, not a single page; and the latter report is merely supplementary to the former report. If you have had much experience in committees of legislative bodies, especially where the committees are composed of numerous members, you will appreciate the difficulty of obtaining a unanimous report, either in matter or manner such as the subject may seem to require. Indeed, the documents annexed to each report, are neither the kind that I would have voluntarily selected myself, nor have they the boundaries I should have given to them, nor have they even the arrangement which the order of dates alone would require. Besides, there are subsequent difficulties, to which I cannot now conveniently allude. With respect to your suggestion, that the business of petitioning annually would be more profitable, if I could get half as much as the clear profits of the printers of the documents, the idea might have been better expressed by saying it would be less ruinous to my interests. Since the 11th February, 1837, when I arrived at New Orleans, to the present period, employed solely in promoting the business of my petition, my cash expenditures have far exceeded the value of any township of land in South Florida, if not the whole cost of printing the reports. And as I have no income independent of my professional labors, the cessation of them doubles my losses.

* * *

H. PERRINE.

P. S. Inclosed are four seeds or beans of the *dolichos tuberosus*, or turnip-bean, or bean-turnip of Yucatan, which produced good edible roots in Baltimore in 1834, although planted as late as the 1st of June.

[With the foregoing letter we received specimens of the prepared foliaceous fibres of the *agave sisalana*, forming the coarse but strong Sisal hemp, those of the *musa abaca*, or finer Manilla hemp, and the still finer and softer pine-apple flax, or prepared fibres of the *bromelia pita*. Of the last, a notice was published in this journal, copied from a late English publication. The sight of these beautiful specimens caused to be formed a much higher estimate of the value of these products, than mere description could have done. We wish success to Dr. Perrine's application to Congress, and to its general objects. We can well sympathize with a man of enthusiastic zeal, who has been for years laboring, without encouragement or success, to serve the cause of public improvement.

The seeds of the turnip-bean have been placed in the hands of a gentleman who will do justice to the experiment of their cultivation.]—ED. FAR. REG.

ANALYSIS OF THE SANTEE MARL.

In the latter part of our fifth volume, (page 693,) there was published a letter from F. H. Elmore, esq. describing the marl found in South Carolina on the banks of the Santee, and which accompanied a specimen of the marl in question. We then, upon very slight examination, merely reported that the marl was very rich; and promised a careful analysis, and a report of the results, at a time of more leisure. We are now enabled to state, from recent examination, that the specimen sent was almost a pure carbonate of lime, as it contained more than 98 per cent. The small residue is of very fine clay and vegetable matter, with a minute proportion of silicious sand. The lump was almost as white, and very similar in other respects, (as it was entirely in chemical composition,) to English chalk; the only certain difference being that the American earth is not fit to mark with, like the English. No true chalk has yet been discovered in this country. From the unexampled richness of this specimen, if considered as *marl*, we strongly suspect that there was sent to Mr. Elmore a specimen of the richest parts, and not one selected fairly to show an average quality. We therefore, without further light on the subject, would place more confidence on the analysis reported by our correspondent J. D., on page 173 of last number, as showing a usual or average strength. That marl was from the same part of the country, and doubtless was part of the same deposite, and contained 88 per cent. of carbonate of lime; which is rich enough to induce even the most lethargic of the South Carolinian land-holders to commence its use. We rejoice to learn, from the statement of J. D., that the reproach which, in this respect, has lain on the otherwise energetic and enthusiastic people of South Carolina—and which we have not been backward in urging against them—is now in course of being removed. For, sure we are, that if marling is once tried there, and the effects seen, it is impossible but its use will be rapidly extended. Absence from home prevented our seeing the letter of J. D. until it had been printed; or these remarks would have been made at the time of its publication.

FROM THE PROCEEDINGS OF THE PLANTERS' SOCIETY OF MONTICELLO, S. C.

Report of the Petitioning Committee.

To the Monticello Planters' Society—

At your last meeting, a committee was appointed to petition the Legislature, on behalf of this Society, that it be incorporated, and such other encouragement given, as the State Assembly, in its wisdom, might deem proper. It surely is within the ordinary range of legislative business, to grant Acts of Incorporation: but what is meant when the planter asks for legislative encouragement? On this point, your committee, acting in perfect accordance with your expressed wishes, prayed the state to adopt some course, which would advance the agricultural interests of the whole community—such a course too, as in its results, could not have been construed into an act of partial legislation. We petitioned that body more particularly to appoint a state agricultural surveyor, who should be required to survey our territory, that its entire geological and mineralogical resources might thus be developed; and also asked that agriculture should form a necessary branch of education in our schools and colleges. The committee were well aware, that this society, of itself, required no legislative aid, farther than the mere act of incorporation would imply: it will be seen by the last "acts of assembly," this request has been granted, but nothing beyond that was accomplished. The agricultural movements of South Carolina, in her legislative capacity, are unquestionably to be regarded in any other light than creditable, or, we might add, even respectable.

In similar instances, what has been the action of a few of the other states of the confederacy? In 1836, Maine *imported* 150,000 bbls. of flour: her legislature votes a bounty to the wheat-grower; and the consequence is, her barren lands yield a doubled produce for domestic consumption, *with a large surplus for exportation.* Connecticut has also been benefited in her agriculture, through her legislators *acting* as if they thought the planter within the pale of some legislative protection or cognizance. Massachusetts, within the last two years, has ordered a general agricultural survey of her domain. North Carolina, "according to the report of the civil engineer in 1826," had a vast quantity of lands "covered with waters," and susceptible of being reclaimed: recently, she has voted upwards of $200,000, to be expended in draining off these waters, that lands so fertile might be thrown into cultivation. The Editor of the Farmers' Register (from whose periodical much of the detail in this report is collected) has been using no ordinary zeal and ability to bring this subject in its proper bearing before the Virginia assembly; but Virginia as yet has done possibly less in this way, than South Carolina

Not twelve years ago, "the Agricultural Society of South Carolina" was founded: it promised exceeding fair things, though like many other bubble societies, it scarcely outlived its organization. About the same time, Dr. Cooper presented a document to the legislature, in which he very forcibly urged the expediency of establishing an agricultural professorship in the college over which he then presided: the subject-matter of that document, we presume, was perhaps too utilitarian for the consideration of legislators, whose tenure of office was held at the pleasure of those very planters, whose social and political condition the report was designed no doubt to reach and improve. If there was a necessity *then* for an amelioration of the planter's pursuit, your committee would suppose the occasion more imperatively demands it *now*, when our lands are impoverished, and our population absolutely driven, by state policy, to seek their fortunes in the fields of the west. When Washington recommended an American agricultural board on the English plan, he in all likelihood could have little dreamed that the almost unbounded territory, to which he gave birth, would in less than a century be importing breadstuffs, to support a comparatively sparse population; yet such is the fact, disgraceful as it may seem. It is proper, it is obligatory on the states within their own limits, to apply the remedy to counteract this or any like evil: and so far as South Carolina is concerned, your committee conceive that, as she takes the usual care to collect the landholder's tax, she should be willing to return some sort of equivalent.

All which is respectfully submitted.

B. F. DAVIS, *Chairman, pro tem.*

March 7th, 1838.

CORRECTION OF A MISTAKE. CROPS ON THE RIVANNA.

To the Editor of the Farmers' Register.

May 16th, 1838.

On a late visit from an old and highly esteemed friend of the county of Culpeper, who, from the situation and character of my farm, was led to enquire into the authorship of a piece signed "Rivanna," appearing in the January No., 1836, of your Register—I was induced to correct a false impression which I learned had been made in his section of country, as to the produce in corn of a certain field, the subject of the above communication. This impression was derived from a difference in the mode, not of measuring, but of *counting* measure, in the two countries—in his, by bushels, in ours, by barrels—where, as in Culpeper, we allow five bushels of shelled corn, and twice that quantity of ears, to the barrel. The specification *ears*, was used merely in exclusion of nubbings, of which there was the usual proportion (not counted) in this crop.

In making this explanation, I am constrained by a sense of the importance of particularity in all such communications—considering a departure from it the height of injustice to our fraternity, and to the cause of agricultural improvement—

to correct a trifling error which in some way had crept into the calculation of product of the field alluded to. As some salvo, however, to the pride of veracity and of *counting* of "Rivanna," he has at command data which establish the yield per acre on a fraction less than sixty, to have been twelve barrels, one bushel, and one peck—making the whole quantity, as before reported, 740 barrels of shelled corn. This result was ascertained by a gentleman of high character and acquirements, from the most accurate measurement of square pens containing about 200 barrels each, built with workmanlike precision of straight pine poles; and calculated according to the most approved mode of gauging; which, after corn has *settled*, (particularly in large pens,) will overrun considerably on being measured out by the *tub*.

You will, I hope, Mr. Editor, excuse my having *raked* up an old subject, which might have been allowed, like its own stubble, to die a natural death; but having given to it in the first instance "a local habitation," I feel in the spirit which then prompted me to obtrude it on your readers, a resolute determination to aid in rescuing this portion, at least, of the state in which I live, from an opprobrium that has for more than half a century rested on it—by showing that luxuriant crops of all kinds may be reared on the roots of *huckle*-berry, running-brier, and *persimmon*—meaning no *personality* to some of my brethren of the plough and pen, and to say nothing of *sheep-sorrel, et multis aliis*, of the pests which infest our land.

Most gladly would I redeem the annoyance that this long vaunted crop must have cost yourself and readers, by the promise of another equally good on the same field and with the same work; but this can hardly be hoped for in so unpropitious a season. The cold and dry weather retarding vegetation, and, in doing so, favoring the ravages of innumerable worms, insects and birds on the seed and plants of this crop, and thus throwing together the working of *it* with the preparation for and planting of tobacco, as well as other business of a farm, on which, under good management, *each* should have its allotted time, must embarrass exceedingly the *mixed* operations of farming and planting, which belong peculiarly to our middle region. RIVANNA.

From the Farmer and Gardener.

PATENT BANKING AND DITCHING MACHINE.

We had an opportunity of seeing on Monday, in full operation, a machine for digging ditches, and at the same time making embankments or dikes, which surpasses any thing of which we had formed any conception. The contrivance consists of a wooden foundation of about twelve feet in length, at one extremity of which are two uprights. In these uprights an axle revolves, on which are two arms of cast iron, having at the extremity of each a cross-piece furnished with four or five teeth, as they may be termed. Inside of these cross-pieces are buckets that receive the earth loosened by the teeth, and, as the axis revolves, deposit their contents on an inclined platform, from which the earth passes and forms an embankment on one side of the ditch. The axle is made to revolve by means of cog-wheels connecting it with the gearing. This gearing consists in part of an iron shaft that passes horizontally and a little obliquely in front, and is turned by a capstan. The capstan is provided with a long horizontal arm to which the horse, by which the whole machine is set in motion, is attached. In acting upon this arm the horse walks around the capstan and crosses of course the line of the ditch, but in advance of it. In order to give direction to the machine and prevent it from being drawn aside, there are two guide wheels with sharp edges in the forward portion of the foundation, that cut the sod to the depth of about eight inches. The ditch on which the machine was employed when we saw it, was three feet deep, and three feet and a half wide at the top. It was excavated in an uncommonly hard virgin clay soil, such as is found on the high ground between Fell's Point and the Canton race course.

We were much surprised at the rapidity and perfection with which the excavation was formed, one foot of finished ditch of the breadth and depth mentioned, together with the dike, being formed in a minute, or sixty feet in an hour. It is calculated that a single horse of ordinary strength can propel the machine during ten hours of each day, consequently the extent of trench formed would be six hundred feet. To give an accurate description of this surprising process within the limits of a paragraph, cannot be done, and we must therefore request such as may wish to form a just conception, to witness the performance. In ditching and draining low lands, or dividing prairies where wood is scarce and the soil light or moist, the machine will prove invaluable. The inventor is Mr. George Page, of Keene, N. H. who, as we are informed, undertook to make something answer the purpose at the suggestion of a gentleman at Washington, whose residence is where much draining is required, and but little wood grows. Mr. Edwards, agent for the Sandwich and Boston Glass Company, will furnish any information required.

The above machine has been made for Col. S. D. Wilkens of this city, for the Territory of Wisconsin, in the prairie parts of which it must prove invaluable.

From the Genesee Farmer.

MANUFACTURE OF BEET SUGAR.

The German improvement over the French method of making beet sugar, a patent affair in Europe, consists *simply in drying the beets*, which are then reduced to a powder by grinding, and changed into a decoction by adding water. The experiment has been thoroughly tried by Mr. Zachariah Wilder, of this town, which resulted in *complete success*. Mr. W. by this process, which, we understand, is as simple as that of making a cup of tea from aromatic herbs, has succeeded in extracting *ten per cent. of sugar from the crude beet*—and he is confident that at least *twelve per cent.* can be obtained at another experiment. For his efforts in prosecuting his experiments to signal success, Mr. Wilder deserves the unqualified thanks of the agricultural world. The result of his labors will give an impetus to the culture of beets in Hampshire county, which cannot fail to be productive of lasting good. But to the process again. The dried powder of the beet was found to yield its saccharine immediately, as the decoction was found to be as sweet as boiled maple sirup, the moment the water was added to the powder. The means used for the clarification of the decoction were very simple. Animal charcoal and lime were the only agents employed. This eminently successful experiment proves the fact, that the immensely important article of sugar can be manufactured by any intelligent farmer's household, as easily as bread, pies or cakes, can be made and baked. A rich garden spot of a quarter of an acre, can produce beets enough to make a thousand pounds of sugar; no heavy capital or incorporated company is required to carry on the business. Every individual can make a pound of sugar as cheaply and as easily as he can make a pound of Indian meal. This important fact has just been proved. Now let us look at the amount of sugar brought into Northampton last year. Why, it amounted to *one hundred and seven thousand pounds*, which, together with molasses consumed, would cost over $10,000. This is no inconsiderable sum to be expended by our citizens annually. A dozen resolute farmers, by their *influence* and labors combined, can create that sum from their lands this summer in the culture of the beet. At least, so we think.

PROGRESS OF THE MANUFACTURE OF POUDRETTE IN THE CITY OF NEW YORK.

To the Editor of the Farmers' Register.

New York, May 14th, 1838.

You have probably noticed in the New York Farmer, that I have been engaged for some time past in introducing an improvement in "*city economy*," by which the contents of privies (an article of great value to agriculture, now thrown away, and *worse* than that, as they are *deposited in the rivers around the city*, instead of being, as I trust hereafter they) are to be converted into an inoffensive and portable manure.

The subject was brought to my attention by a French gentleman who is familiar with the process in his native country, and who is now engaged with me in the operation here. We have had many prejudices to combat, on account of the nature of the business, and many difficulties to encounter, in consequence of the general derangement of business, which have delayed our operations; yet we are now preparing about 60 bushels of poudrette daily, and have a prospect of doing much more after a short time, when other business will have resumed its accustomed activity, so that a few additional shares of our stock may be paid for, which will enable us to increase the number of teams required to "remove the deposites." Of the value of poudrette as a manure, no person of my acquaintance, familiar with its preparation, entertains a doubt; yet there are few persons in this country who are sufficiently acquainted with its use to appreciate duly the benefits which will surely result from the labors of those who shall introduce a mode of preparation by which the immense amount of valuable material, now thrown into our rivers, and of course a *nuisance* to all classes of the community, shall be converted into an inoffensive, portable and highly valuable manure. The process of preparation, in my opinion, does not materially, if at all, deteriorate its value, as I will satisfy you when you will visit our works. That you may be better acquainted with the article, and have an opportunity to test its value, as well as its inoffensive character and portability, I send you a barrel, and shall be much obliged by your using it for any kind of vegetables, or grain, or on grass, as may be convenient for you, and noting its effects as compared with other manures. I cannot give practical instruction as to the best mode of application, but will observe that I am using it in my garden for experimental purposes, by putting some in the hill, some in drills, and spreading some broad-cast and raking it in.

I estimate its strength, or value, in the proportion of one bushel of *poudrette*, to eight or ten bushels of good stable or barn-yard manure, and equal bushel for bushel to bone dust. We have not yet, for want of means to extend our works, been able to furnish a bushel to any person except those who have taken a share or shares of our stock, although numerous applications have been made for it in small and large quantities, as well by gentlemen in neighboring states, as by those in this vicinity. To those who pay in $100, or take a share, we furnish *two hundred* bushels of poudrette as their annual dividend, within *three* and *six months* from the time of payment, which is equivalent to *sixty* per cent. on their investment, as we can receive thirty cents at the works for every bushel we can make.

We hope soon to be able to extend our works largely in order to increase the quantity prepared, so as in some measure to supply the demand for the poudrette.

I am in hopes that important benefits will result from this new source of improvement to agriculture. I say *new* source—it is new in *this* country, at least to much extent. The inquiry is "*how*," and "*how much*," to use—not is it *useful*; as every person, at all conversant with such matters, understands the value of the *raw material*, as well as the difficulty of its application.

I hope to hear from the *effects* of the barrel sent to you.

With much respect, I am very truly yours,

D. K. Minor.

From the Genesee Farmer.

RAISING CLOVER SEED.

In raising clover for seed, in order to procure a good crop, it is first requisite that the land be fertile: that it be well prepared before sowing; and that a sufficient quantity be sown to yield a full and even crop.

The second and most difficult object to attain, is to secure the crop when ripe, so as to save the largest portion possible of the seed. To do this, it must be cut at a proper season. As the seed ripen at different periods, if the crop is cut too soon, there will be a loss sustained from the immaturity of the seed. If cut too late, those seed first ripe will be liable to be entirely lost by being shattered off in the field. Hence there is a certain medium to be observed, to prevent these two evils, which is, to cut the crop when about two-thirds of the heads have become black; a large portion of the remainder will ripen by the nourishment they obtain from the straw during the drying process. Where the clover is not lodged, it is much the best to cut it with a cradle, laying all of it in double swaths; and securing the heads from falling through the fingers of the cradle by stitching a piece of linen cloth upon them.

After the crop is cut, it must be suffered to remain in the field long enough to become dry; this, if the weather is good, will be in a very few days. It must then, when the dew is upon it, be raked into small bunches, (such as would be a convenient load for a fork,) and when sufficiently dry, placed carefully upon a sled or wagon, and drawn into the barn. If the weather is unfavorable, it becomes necessary to turn these bunches repeatedly, to prevent their being injured by the moisture. Indeed, this should be done even in fair weather, if they remain out longer than two or three days. When drawn into the barn, the crop may be either stowed away in mows, or else thrashed out immediately, and the heads and chaff placed in a room for the purpose, for ultimate cleaning. This may most generally be done best in winter.

If farmers could always raise their own seed, and in sufficient abundance, it would be much better to sow it in the chaff, as it is generally found to be more certain to grow. The only advantages of cleaning are, the more exact determination of the *quantity* to be sown, and the more equal distribution of the seed; and where it is raised for sale cleaning is of course requisite. When sown in chaff, the difficulty with regard to quantity and distribution may be obviated by sowing sufficient to insure the desired thickness on every part of the ground.

By far the best method of cleaning is by means of a machine; but as this is not always to be had, the practice of treading it out by horses is then to be resorted to, though it is tedious and unpleasant. It is thus performed. The barn floor is covered with chaff about a foot in thickness, and the horses are driven upon it one day. The next morning it is to be passed through a fanning mill, and the chaff and dust which has been beaten off will be blown away; the clean seed will pass through the screen; while a third and larger portion, containing the seed yet in the chaff, will drop in the rear of the fanning mill. This is to be spread a second time upon the floor, mixed with a fresh portion of unseparated chaff, and again trodden by the horses; the second morning repeat the same operation, and a much larger portion of clean seed will be obtained. The operation is thus to be repeated until the whole of the chaff is separated.

In order to clean the seed properly for market, it is necessary first to run it through a sieve of just such a degree of fineness as to permit the clover seed to pass through, but retain all large substances. It must then be passed through a sieve just fine enough to retain the clover seed, but to suffer all smaller seeds to pass through. In this way it is effectually cleaned.

By proper attention and care, three or four bushels may be easily obtained from an acre of land.

J. J. T.

THE ADVANTAGE OF USING SUB-CARBONATE OF SODA IN WASHING CLOTHES.

[The following short article was before published in the Farmers' Register, nearly three years ago; and the since well-tested value of the practice induces us, contrary to our usage, to re-insert the directions, for the benefit of the many later subscribers, as well as the many older ones, who passed over the former publication without notice. The saving of labor by using this plan, is thought to be so great by some of the ladies of our acquaintance, that if nothing else had been gained by their husbands from the Farmers' Register, they think that for this little article alone they might well afford to pay a subscription for life.

As it may not always be convenient, in country places, to obtain lime-water, cheap as it is, it is proper to say that that ingredient may be omitted without sensible injury to the process. The sub-carbonate of soda is now getting into extreme use for this purpose, and may be bought at any apothecary's shop, at 12½ cents the pound.—ED. FAR. REG.

[From the Essex North Register.]

In this day of improvements, few have been suggested of more importance, especially to females, than the new mode of washing clothes, which has been introduced into this town [Newburyport] through the agency of two benevolent individuals, now residing at a distance from us. It has been tried by quite a number of females with complete success, and those who have tried it are desirous of communicating it extensively, that others may reap the same benefit which has accrued to them. It is to be used only for white clothes. It does not answer the purpose in case of calicoes and woollens.

1. *Mixture*—Five gallons soft water, add half a gallon of lime water, a pint and a half of soft soap, or a pound of hard soap, and two ounces of carbonate of soda.

2. *Method of washing*—Soak the clothes over night if very dirty, at any rate wet them thoroughly before putting them into the mixture. When the above mixture is at *boiling heat*, put in the clothes that have been soaked or wet, merely rubbing those parts with a little soap that are unusually soiled. Boil them *one hour*. They are then to be taken out and drained, and thoroughly rinsed in warm water, then in the indigo water as usual, and they are fit for drying. The lime water may be prepared and kept on hand—the soda, sub-carbonate, (be sure to get the right kind) may be procured cheap, by purchasing it in a large quantity. Let all who feel that washing-day is a day of hard work and weariness, cease to complain, until they are willing to try this safe, easy and expeditious mode of lightening their burdens.

From the Franklin Farmer.

BLUE GRASS.

This grass, which constitutes the glory of Kentucky pastures, is esteemed superior to all others for grazing. It flourishes only on calcareous soils. Opinions and practice vary here, as to the best time of sowing it—some preferring September, for the same reasons, chiefly, which relate to timothy or other grasses, others preferring February or March, to obviate the danger of the tender roots being winter killed. It is sown either on woodland or open ground—in the latter case most generally after a succession of exhausting crops in old fields. If sown on woodland, the leaves, brush and trash must be raked off or burnt. It is particularly important to burn the leaves, else the seed may be blown away with them by the wind, or if not blown away, the leaves may prevent the seed reaching the earth and thus defeat their germination. Many of those who sow in winter, prefer casting the seed on the snow, as it enables them to effect the operation with more neatness and uniformity. In woodlands, the grass must not be grazed the first year, or at all events till after the seeds have matured. In open land, the practice has been adopted by some, of mixing timothy and clover with blue grass, in which case, half a bushel of the latter seed to the acre, is sufficient. The advantage resulting from this is, that it secures at once, a well covered pasture that will bear considerable grazing the first year. The blue grass, in a few years, expels the other grasses, and takes entire possession of the field. On open ground, it is frequently sown in March upon wheat, rye or oats. If the season is favorable, it may be sown in April; but should the weather prove dry, a great portion of the seed will be lost. It is the practice, we believe, of most graziers, to put upon a given pasture, as much stock as it will maintain, without shifting them during the season, as, besides saving labor, it renders the cattle more quiet and contented. Others, however, fence off their pastures into separate divisions, to undergo a regular succession of periodical grazings. This plan secures a constant supply of fresh grass, very grateful to the animals, and is believed to be more economical, as much less is trampled and rejected by the cattle. The number of animals to the acre, must depend upon their size and the quality and quantity of grass. The grass on open ground is much more abundant, sweet and nutritious, than on woodland, and consequently will maintain much more stock, perhaps nearly twice as much; while open woodland will produce much more and better grass than that which is deeply shaded. The best graziers extirpate, as fast as possible, every tree not valuable for timber or wanted for fuel, and some even prune the branches of those which are allowed to remain. But we shall soon, we hope, be able to present this subject more at large, in some numbers which are preparing, on the grazing and stock-feeding systems of Kentucky, which we trust will prove interesting to all our readers and particularly instructive to the farmers in the southern portion of the state and Tennessee. Although we wish well to the tobacco growers on Green river, and would cheerfully lend our aid to promote their particular interests in that pursuit, we wish they could be persuaded to adopt, in its stead, the grazing business; for we are confident it is a much more productive, and certainly a more agreeable and less laborious one.

From the Genesee Farmer.

BEST TIMBER FOR PUMP LOGS.

Friend Tucker—It may be thought too aspiring by some, for an old man of 82 years of age, to begin to write for newspaper inquiries; but seeing some inquiries and communications in several of the numbers of this year's Genesee Farmer, respecting the best method of conducting water in logs to the place desired, I would inform friend Southhill, as I have had some experience in conducting the water to my house from a distance, near forty years, in logs, of the sort of timber I used, and the manner of laying the logs, in as concise a manner as I can, and the length of time they have been in operation, from actual experience. The timbers used were all poplar (or what is called the tulip tree), except three logs, two of which were white oak, the other of chestnut—all green, with the bark on, of the size of from one foot to fifteen inches in the but-end, and not less than eight inches in the top-end. They were bored with an augur of two and a quarter inches, and put together similar to a pump, but without any iron bands. They were put in a trench three feet deep, in the year 1797, the 8th month. They answered every purpose I could expect, until 1830, at which time some of the joints began to leak. In the year 1835, I had them taken up, as they were not likely to convey a sufficient quantity of water. The distance from the spring-house to the head of the spring, was 33 poles, and the descent three feet. The end of the pipe in the spring-house was 18 inches higher than the rest, until within three or four poles of the spring-head, for the purpose of keeping the air out, to prevent it from rotting. The logs were from fifteen to twenty-eight feet long. When taken up, it appeared that the deficiency was at the joints, the hole being worn to the size of four, and some five inches, which originally was but two and a quarter inches. A number of the joints were worn entirely through, the small end having been tapered to join them together. I had the pipes laid the second time, with timber similar to the first, one half new logs, the other half were of the best and largest of the old logs that had been in 38 years, and appeared to be in good condition.

I had them laid in a different manner. All the logs were cut square at the ends, and were joined together by a band or ring of iron from seven to eight inches in the clear, three inches broad and one-eighth thick, sharpened at both edges and drove in between the ends of the logs so as to leave an opening between of half an inch, which was filled with slacked lime before covering, to prevent the iron from rust. In order to have the bands extend equally in both logs, I had a chisel made the same circle of the bands, three inches wide, and drove in each end of the log one inch, previous to putting them together. There has not been the least appearance of any deficiency at this time.

A PENNSYLVANIA FARMER.

Wood Lawn, 4th mo. 10th, 1838.

From the Genesee Farmer.

BARLEY.

The increasing attention which is paid to the culture of barley—the profits of the crop—its value as a preparative for wheat—and the favor which it finds as a substitute for wheat in making bread, are entitling it to a high rank among the grains cultivated in this country.

According to Loudon, there are six species and sub-species of this grain in cultivation, besides varieties.

Hordeum vulgare, or spring barley, is distinguished by its double row of beards or awns, standing erect, and its thin husk, which renders it favorable for malting. This is the sort commonly grown in the southern and eastern districts of both England and Scotland.

Hordeum cœleste, or Siberian barley, is a variety of early or spring barley, much grown in the north of Europe, having broader leaves, and reckoned more productive than the other.

Hordeum hexastichon, winter barley, or as it is called in Scotland, square barley, is a variety known by having six rows of grains, large and thick-skinned, and for that reason not considered as favorable for malting.

Barley bigg, is a variety of winter barley, known by its always having six rows of grains, by the grains being small and thick-skinned, and being earlier than the preceding or parent variety. It is hardy, and chiefly grown in Scotland.

Hordeum distichon, common, or long-eared barley, is known by its long spike or ear flatted transversely, and its long awns. It yields well, though some object to it, because the ears being long and heavy, they think it apt to lodge.

Hordeum distichon nudum, or naked barley, is known by the awns falling easily, and when ripe, almost of themselves from the chaff, when the ear somewhat resembles wheat, and by some is called wheat barley. It is spoken highly of in the British Husbandry, as being hardy in growth, strong in the stem, tillering with great vigor, and producing abundant crops of fine grain. By some, this variety is considered the same as spelt wheat, which indeed it strongly resembles. It is six rowed.

Hordeum zeocriton, sprat or battledore barley, is known by its low stature, coarse straw, short broad ears, and long awns. It is but little cultivated.

New varieties of barley are produced in the same manner as in wheat, by crossing, and some of the most celebrated kinds, such as the chevalier, annat, &c. have originated in this way.

In this country but two varieties are sown, and these are familiarly distinguished as the two and the six-rowed. They are always sown in the spring; no kind in the United States being able to endure the severity of our winters, or at least we know of no variety which has been attempted here as a winter or fall-sown grain. The comparative value of the two varieties does not seem to have been fully decided by our farmers, some preferring one kind and some the other. That the two-rowed will make the most flour from a given number of pounds—that its thin skin renders it more suitable for malting—and that it is rather less liable to be affected by smut than the six-rowed, seems to be generally conceded; but its productiveness is much disputed, and it would seem with some reason, as the greater length of the ear in the two-rowed, would hardly compensate for the greater number of rows in the other variety. So far as we are able to judge, however, from the opinions of experienced farmers, the preference, for the reasons assigned, is becoming more decided in favor of the two-rowed.

Barley of every variety requires a rich, friable and mellow soil, which retains a moderate quantity of moisture, but without approaching to that which may be denominated wet; as for instance, land which contains from 50 to 65 per cent. of sand, and the remainder chiefly clay, though in situations where the climate is usually moist during the summer, it may be grown where sand is in the soil in a larger proportion. It succeeds best in what farmers term a rich deep loam, and with too much sand, or too much clay, will not produce good crops. With the single exception, that it will succeed with less lime than wheat, soils that will produce good wheat, will also grow barley to advantage.

It is probable that more barley is grown in the state of New York than in all the rest of the United States, and the section in which it is produced in the greatest abundance and perfection, is the northern slope of western New York. The ranges of towns which mark the geological separation of the argillaceous and limestone districts, have hitherto yielded the greatest quantities of barley, and in them the culture is still rapidly extending. On this slope, it is found that soils on which winter wheat without extra care in cultivation, is very liable to freeze out in the spring, will produce heavy crops of barley, and hence clover and barley on many farms have taken the place of clover and wheat, affording about the same profit in the crop and at a less expense of labor. This is particularly the case in the country reaching from the Oneida to the Canandaigua lakes, including a part of Madison, Onondaga, Cayuga, Seneca, Yates and Ontario counties. On what is called the great limestone region of west New York, wheat will undoubtedly be preferred to barley as an article of culture; and it may be remarked as a general rule, that on all soils where good barley can be grown, the suitable application of lime will ensure the success of wheat.

Perhaps there is no crop which demands and repays thorough working of the soil better than barley. The surface when fitted for the reception of the seed, can hardly be made too fine; and the excellence of the crop is greatly dependent on this point. A crop that occupies the ground so short a time as barley, spring wheat or oats, can hardly be benefited by manure applied directly to them, unless in a thoroughly decomposed state; and hence it has been found by experience, that these crops succeed better after hoed or root crops to which the manure has been applied, or on turf lands that have received a top-dressing of manure, and been carefully turned over in the fall of the year. The practice, somewhat extensively followed, of sowing winter wheat after barley, has led to the application of the manure to the barley crop; and perhaps where hoed crops cannot precede, this is the preferable way, though there is a great risk of too much straw, and the consequent lodging of the barley before ripening.

Barley should be sown in all cases, as soon as the ground is sufficiently dried and warmed to allow the seeds to germinate freely, and place them beyond the danger of injury from frost. Early frosts are more fatal to barley than to spring wheat or oats, and more injurious on wet or low lands than on dry or elevated ones. Particular attention must be paid to the dryness of the soil at the time of sowing, especially if naturally inclining to wet, as on such soils a wet spring will starve and destroy the plants. "Steeping the seed for twenty-four hours in soft water, will cause the grain to germinate at the same time; and this, if it is sown at a late period, is of more importance than may be generally imagined, as it is otherwise apt to ripen unequally." (Brit. Hus.) The finest, heaviest samples of all grains are usually obtained from early sown fields; and the difference in weight in barley and oats, is from one-fifth to one-third in favor of early sowing. The smut is the only disease to which barley is subject, and this is rarely a serious injury, where the crop is grown on favorable soils, or the seed is put in in good order. The worm which has proved so destructive to wheat in the eastern counties, has also injured the barley in a considerable degree; but in west New York, we have neither seen nor heard of its appearance in this grain. The wire-worm is sometimes very destructive to the crop when young; and in some seasons, the meadow mole, so called, when the grain approaches maturity, makes sad havoc by cutting down the plant to get at the ears; an effect more often observed when the barley is sown on turf leys, as they will rarely lie so close as not to leave numberless hiding-places to the animal.

In sowing barley, as in most other crops, the universal experience of English farmers, and the directions of the best works on agriculture, go to establish the fact, that less seed is required on rich lands than on poor, and that the quantity of seed used should be increased in proportion to the lateness of the sowing. In European countries, from ten to eighteen pecks per acre is used; sixteen being the quantity usually recommended; in this country from two to three bushels is considered sufficient for the acre. The two-rowed requires less than the six-rowed, as it tillers more vigorously; and if sown too thick, the plants will be weak and ripen irregularly.

Both the quantity and quality of the product depend on the soil, and the variety of the grain sown. In this country, the average crop may be stated from thirty to thirty-five bushels per acre; in England, the average produce is estimated at thirty-two bushels. Middleton says, the crop in that country varies from fifteen to seventy-five bushels an acre. The greatest crop we have seen mentioned in this country was sixty-five bushels per acre, and that was grown on land from which several crops had been taken in succession. In an experiment made by the East Lothian Agricultural Society upon the chevalier, and a common sort of barley, both sown on a light gravelly soil, the produce of each per imperial acre, was—chevalier, 65 bushels 2 pecks of grain, weighing $56\frac{3}{4}$ lbs. per bushel. Common barley gave 61 bushels 2 pecks of grain, and weighed $54\frac{3}{4}$ lbs. per bushel.

Good qualities of the two-rowed, will average about 52 or 53 lbs. per bushel; but the winter, or six-rowed varieties, will not exceed 43 to 46 lbs. The difference in malting is great; the experiments of Dr. Smith, showing that a Winchester quarter of the several varieties, when malted, would produce the following quantities of proof spirits, viz:

English barley	about	$21\frac{1}{4}$	gallons,
Scotch barley	"	$19\frac{1}{4}$	"
Scotch bigg	"	$16\frac{1}{4}$	"

Or that English barley was 11 per cent. superior to Scotch, and full 12 per cent. above Scotch bigg, or winter barley.

The value of the several kinds of grain as an article of food, may be estimated from the following table; the quality of the flour being good household or family flour.

Wheat, if weighing	60 lbs. of flour	48 lbs. of bread	64 lbs.
Rye,	54	42	56
Barley,	48	$37\frac{1}{2}$	50
Oats,	40	$22\frac{1}{2}$	30

(*Brit. Hus.*)

The analysis of barley by Sir H. Davy, gives as contained in 100 parts:

79 per cent. of mucilage or starch,
7 of saccharine matter,
6 of gluten or albumen.

Owing to the deficiency of this latter substance, or gluten, barley flour, like that of oats, buckwheat or potatoes, cannot be made into bread alone, but is mxied with wheat flour, or eaten in the form of cakes, when it is very wholesome and palatable.

Barley is perhaps one of the most difficult of the grains to secure in good condition; as, if suffered to stand until the berry is perfectly dry and hard, the head will frequently drop down, owing to the brittleness of the straw; and if cut too early, the grain will shrink and lose in weight; and as it cannot when cut in an unripe state be put into barns or stacks without certain injury by heating, so in unfavorable weather it is very apt to become of a black color, and lose the clear yellowish-white tinge so characteristic of good and well-cured barley. The usually fine state of our atmosphere, and the clear dry air of our summers, render the proper curing of barley a much less difficult task here, than in the moist climate and cloudy skies of Great Britain.

Before the introduction of threshing machines, barley, though easily threshed by horses or by hand, was with great difficulty prepared for market, owing to the obstacles offered in separating the awn from the kernel; and at the present time in many districts of England, and most parts of the continent, the *hummeling*, or freeing the berry from the beard, is one of the most laborious and difficult processes in the culture of barley.

Barley is extensively used in the fattening of pork, for which purpose it is admirably adapted when prepared by steaming or grinding; and in the districts where it is grown, is an excellent substitute for the corn crop, which for a few years past has been a partial failure. It is also used in large quantities in our breweries, and in too many instances takes the place of rye in the manufacture of whiskey. As a feed for horses it is not generally approved, but for fattening cattle, hogs and poultry, it is highly prized. Before the system of cutting straw, or manger-feeding was generally adopted in Great Britain, barley straw, owing perhaps to its being cut early, was used as food for cattle in preference to others, as cattle could eat it uncut more readily than the harder straws. Wheat or oat straw is now preferred when it is to be converted into chaff, or cut fine for mixing with hay or roots. There are varieties of barley found in the shops, pearl and Scotch, both of which are prepared by divesting the kernel of its husk in mills, resembling in some degree the rice-mills of the south; and in the case of the pearl barley, the grinding or rubbing is continued until the berry assumes a smooth round form. Few articles are more nutritious, or better adapted to the stomachs of the weak or the valetudinarian.

From the London and Edinburgh Philosophical Magazine.

ON THE FORMATION OF MOULD.

By Charles Darwin, Esq., F. G. S.

The author commenced by remarking on two of the most striking characters by which the superficial layer of earth, or, as it is commonly called, vegetable mould, is distinguished. These are its nearly homogeneous nature, although overlying different kinds of subsoil, and the uniform fineness of its particles. The latter fact may be well observed in any gravelly country, where, although in a ploughed field, a large proportion of the soil consists of small stones, yet in old pasture-land not a single pebble will be found within some inches of the surface. The author's attention was called to this subject by Mr. Wedgwood, of Maer Hall, in Staffordshire, who showed him several fields, some of which, a few years before, had been covered with lime, and others with burnt marl and cinders. These substances, in every case, are now buried to the depth of some inches beneath the turf. Three fields were examined with care. The first consisted of good pasture land, which had been limed, without having been ploughed, about twelve years and a half before: the turf was about half an inch thick; and two inches and a half beneath it was a layer, or row, of small aggregated lumps of the lime, forming, at an equal depth, a well-marked white line. The soil beneath this was of a gravelly nature, and differed very considerably from the mould nearer the surface. About three years since cinders were likewise spread on this field. These are now buried at the depth of one inch, forming a line of black spots parallel to, and above, the white layer of lime. Some other cinders, which had been scattered in another part of the same field, were either still lying on the surface, or entangled in the roots of the grass. The second field examined was remarkable only from the cinders being now buried in a layer, nearly an inch thick, three inches beneath the surface. This layer was in parts so continuous, that the superficial mould was only attached to the sub-soil of red clay by the longer roots of the grass.

The history of the third field is more complete. Previously to fifteen years since it was waste land; but at that time it was drained, harrowed, ploughed, and well covered with burnt marl and cinders. It has not since been disturbed, and now supports a tolerably good pasture. The section here was, turf half an inch, mould two inches and a half; a layer one and a half inch thick, composed of fragments of burnt marl (conspicuous from their bright red color, and some of considerable size, namely, one inch, by a half broad, and a quarter thick,) of cinders, and a few quartz pebbles mingled with earth; lastly, about four inches and a half beneath the surface was the original, black, peaty soil. Thus beneath a layer (nearly four inches thick) of fine particles of earth, mixed with some vegetable matter, those substances now occurred, which, fifteen years before, had been spread on the *surface*. Mr. Darwin stated that the appearance in all cases was as if the fragments had, as the farmers believe, worked themselves down. It does not, however, appear at all possible, that either the powdered lime or the fragments of burnt marl and the pebbles could sink through compact earth to some inches beneath the surface and still remain in a continuous layer. Nor is it probable that the decay of the grass, although adding to the surface some of the constituent parts of the mould, should separate, in so short a time, the fine from the coarse earth, and accumulate the former on those objects which so lately were strewed on the surface. Mr. Darwin also remarked, that near towns, in fields which did not appear to have been ploughed, he had often been surprised by finding pieces of pottery and bones some inches below the turf. In a similar manner on the mountains of Chili he had been perplexed by noticing elevated marine shells, covered by earth, in situations where rain could not have washed it on them.

The explanation of these circumstances, which occurred to Mr. Wedgwood, although it may, at first, appear trivial, the author did not doubt is the correct one, namely, that the whole is due to the digestive process, by which the common earth-worm is supported. On carefully examining between the blades of grass in the fields above described, the author found, that there was scarcely a space of two inches square without a little heap of the cylindrical castings of worms. It is well known that worms swallow earthy matter, and that having separated the serviceable portion, they eject, at the mouth of their burrows, the remainder in little intestine-shaped heaps. The worm is unable to swallow coarse particles, and as it would naturally avoid pure lime, the fine earth lying beneath either the cinders and burnt marl, or the powdered lime, would, by a slow process, be removed, and thrown up to the surface. This supposition is not imaginary, for in the field in which cinders had been spread out only half a year before, Mr. Darwin actually saw the castings of the worms heaped on the smaller fragments. Nor is the agency so trivial as it, at first, might be thought; the great number of earth-worms (as every one must be aware, who has ever dug in a grass-field) making up for the insignificant quantity of work each performs.

On the above hypothesis, the great advantage of old pasture land, which farmers are always particularly averse from breaking up, is explained, for the worms must require a considerable length of time to prepare a thick stratum of mould, by thoroughly mingling the original constituent parts of the soil, as well as the manures added by man In the peaty field, in fifteen years, about three inches and a half had been well digested. It is probable however, that the process is continued, though at a slow rate, to a much greater depth; for as often as a worm is compelled by dry weather, or any other cause, to descend deep, it must bring to the surface, when it empties the contents of its body, a few particles of earth. The author observed, that the digestive process of animals is a geological power which acts in another sphere on a greater scale. In recent coral formations, the quantity of stone converted into the most impalpable mud, by the excavation of boring shells and of nereidous animals, is very great. Numerous large fishes (of the genus *Sparus*) likewise subsist by browsing on the living branches of coral. Mr. Darwin believes, that a large portion of the chalk of Europe was produced from coral, by the digestive action of marine animals, in the same manner as mould has been prepared by the earth-worm on disintegrated rock. The author concluded by remarking, that it is probable that every particle of earth in old pasture land has passed through the intestines of worms, and hence, that in some senses, the term "animal mould" would be more appropriate than "vegetable mould." The agriculturist in ploughing the ground follows a method strictly natural; and he only imitates in a rude manner, without being able either to bury the pebbles or to sift the fine from the coarse soil, the work which nature is daily performing by the agency of the earth-worm.*

DISEASE AMONG THE SHELL-FISH.

"One of the most curious phenomena of the year (1836) has been the fatal effect of an epidemic disease among the molluscous animals or shell-fish of the Muskingum river, (Ohio.) It commenced in April and continued until June, destroying millions of that quiet, retiring race, which people the beds of streams. As the animal died, the valves of the shell opened, and, decomposition commencing, the muscular adhesions gave way, and the fleshy portion rose to the surface of the water, leaving the shell in the bed of the stream. As these dead bodies floated down the current, the heads of islands, masses of fixed drift-wood, and the shores in many places, were covered with them, tainting the air in the vicinity with putrid effluvia. The cause of the disease amongst the shelly race, remains as much a mystery as that of the Asiatic cholera amongst the human family."—*Dr. S. P. Hildreth, Journal of Science.*

* Since the paper was read, Mr. Darwin has received from Staffordshire the two following statements:—1. In the spring of 1835 a boggy field was so thickly covered with sand that the surface appeared of a red color; but the sand is now overlaid by three-quarters of an inch of soil. 2. About eighty years ago a field was manured with marl; and it has been since ploughed, but it is not known at what exact period. An imperfect layer of the marl now exists at a depth, very carefully measured from the surface, of twelve inches in some places, and fourteen in others, the difference corresponding to the top and hollows of the ridges or butts. It is certain that the marl was buried before the field was ploughed, because the fragments are not scattered through the soil, but constitute a layer, which is horizontal, and therefore not parallel to the undulations of the ploughed surface. No plough, moreover, could reach the marl in its present position, as the furrows in this neighborhood are never more than eight inches in depth. In the above paper it is shown, that three inches and a half of mould had been accumulated in fifteen years; and in this case, within eighty years (that is, on the supposition, rendered probable from the agricultural state of this part of the country, that the field had never before been marled) the earth-worms have covered the marl with a bed of earth averaging thirteen inches in thickness.

From the Genesee Farmer.

GERMINATION OF THE ACACIA OR LOCUST SEED.

Mr. Loudon, in his Magazine of Natural History, states that Sir John Herschel lately sent some seeds of the acacia from the Cape of Good Hope, with directions to scald them to ensure their growth. Mr. L. having received some of them, subjected them to the following experiments:—two were placed in boiling water, and left to soak for an hour, until the water had become cool; two were kept at the boiling temperature for one and a half minutes. Some were sown immediately under a hand-glass in the open border; and the rest were kept for three or four days and then sown in a hotbed. The following are the results:—

Under the hand-glass.

1 boiled	$1\frac{1}{2}$	minutes failed.		
1 do.	3	do. came up in	14	days.
1 do.	6	" "	13	"
1 not steeped at all did not germinate.				

In the hotbed.

1 boiled	$1\frac{1}{2}$	minutes came up in	8	days.
1 "	3	" "	7	"
1 "	6	" "	7	"
1 "	15	" "	13	"
2 in boiling water left to cool			9	"
2 not steeped came up in			21	"

Nothing can more forcibly show the hardness of the envelopes, or the tenacity of life in the acacia, than the germination of the seed after boiling 15 minutes. We have a number of times scalded the locust seed to produce germination, no other mode being so speedy or effectual.

From the Southern Agriculturist.

SUN-FLOWER CULTURE.

Effingham County, Geo. Feb. 10, 1838.

Mr. Editor,—In your last September number, I saw a communication relative to the sun-flower, and as you seem willing to "gather up the fragments, that nothing be lost," I take the liberty of saying, that I have been in the habit of planting the sun-flower a number of years, to a limited extent.

There are several fences, which lead from my yard fence, to the surrounding woods—the weeds and grass growing up in the fence corners, formed ready ways for snakes to visit the yard. To prevent this, the hoe is used to keep these ways clean, and so prevent the temptation to their visits.

Now, while all this operation is going on, I have two hills of sun-flowers growing in every fence corner; two stocks (or say three or four) in a hill, planted early in the spring. About the time that my long forage gives out, these begin to bloom. As the blossoms begin to appear, I cut them off about a foot from the ground, and give to my horses, which eat them very readily,—leaves, buds, stocks, and all. This I consider a very wholesome, as well as nutritious food. Thus the ground that has to be kept clean, to prevent unwelcome visiters, is made in the mean time to yield profitably.

If, in your judgment, you think proper to introduce this scrap to the company of your more useful communications, it is at your service.

A SMALL GOSHEN FARMER.

REMARKS ON, AND SOME OBJECTIONS TO, THE ESSAY ON "AGRICULTURAL HOBBIES AND HUMBUGS."

To the Editor of the Farmers' Register.

May 15th, 1838.

I have been so much amused with your article on agricultural hobbies and humbugs, (p. 47, vol. VI.) and think most of your remarks so perfectly just, that I could hardly prevail on myself to express my dissent from such as I cannot concur in: nor would I do it, but for your often-avowed desire to have all your opinions freely canvassed, where any good to our cause might possibly result from it, in the opinion of those who may differ from you. I have very rarely been among that number; and where I have, it has been, in each case, with much distrust of my own opinion, and not a little fear, that my readers might so far mistake the motives of my communications, as to ascribe them, rather to the silly vanity of seeing myself in print, than to their real cause—which has ever been, the hope of promoting, in some degree, the great object of your paper. With this anchor thrown out to windward, I shall commence my objections.

The first is—for your apparent preference to corn with the largest cobs, of which you say, it "is evidently and mathematically true, if the grains are of equal size, there will be more encircling a *large* than a *small* cob." Now to me it appears "evidently and mathematically true," that this depends upon the grains being of equal *width*, and *not* on their equality of size; for a *broad* grain may be of equal size with a *long* one, although the latter will certainly out-number the former, although the length and diameter of their respective cobs be precisely the same. Again, it "is evidently and mathematically true," that although *one large single ear* with a *large* cob, will have more grain than any *single ear* with a *small* cob; yet, if the small cob variety produces several more ears, under similar circumstances, on a single stalk, of which there are many unquestionable proofs, in regard to the twin-corn, than the large-cob varieties, the former will, with mathematical certainty, produce the most grain. In the case of the twin-corn, fairly and accurately compared with two other very popular varieties, both having very large cobs, I have ascertained by actual measurement, the difference in favor of the twin-corn was as nine to seven.

Your second opinion from which I dissent, is that wherein you say, that "you have no faith either in the reasonings or the supposed results of choosing seed-wheat," either for the large size of the grain, the large number of grains in the head, or the large number of stalks and quantity of grain from a single seed. This seems tantamount to a belief, that the only circumstance worthy of attention in the choice of seed-wheat, or indeed of any other seed, is, to be sure it will vegetate. In other words, that none are susceptible of any improvement worth regarding, merely by selecting that which appears to possess most of those qualities almost universally believed to be essential to the perfection of all seed. I say almost universal, for I do not recollect ever to have met with but one person who entertained the opinion I understand you to express on this highly interesting subject. Possibly, however, I may misunderstand you; and since nothing is farther from my wishes, let me repeat what you seem to me to have said. First, in regard to seed-wheat, that you disbelieve the common notion, that more product can be secured from the land by choosing seed, either for its size, the large number of grains in the head, or the large number of stalks and quantity of grain from a single seed. Secondly, in regard to seed-corn, or any other seed, I understand you to say, that you have not the slightest faith, "that larger crops can be obtained by choosing seed on account of *the form, size, or number of grains, or the size or number of ears, &c.*" Now this "*et cætera,*" I must presume, comprehends all the other qualities usually attributed to, and sought after in seed; in all which, you say, that "*you have not the slightest faith.*" But if none of them are worth regarding, does it not follow, undeniably, that the sole ground of preference left is, that *one* sample will vegetate better than *another?* It is true that you qualify, in some degree, your sweeping anathema against the common creed and practice, by saying—you do not deny—that particular varieties of plants *may be somewhat more productive* than others which are equally suitable to the same soil and climate; yet this is but cold encouragement, and is a very different thing from admitting the fact. Indeed, it seems nearly the same as declaring that you do not fully believe it; although you give us the result of no experiments made by yourself or others to confirm this strongly-implied scepticism. You have classed both the creed and the practice which you condemn, among "*hobbies and humbugs;*" and there is nothing of which your "good-enough" farmers, (by far the most numerous class among us,) have such a mortal dread, as the ridicule attached to hobby-riding.

In another place, speaking of varieties of corn, your infidelity as to their relative productiveness, is not left to implication, for you positively avow that "your views are utterly opposed to the belief, that either the Maryland twin-corn, the Baden-corn, or the Dutton-corn, are more productive in a very great degree, than other varieties in *any* situation;" although it does not appear that you yourself have ever made, even a single comparative trial, to ascertain whether the opinion be true or false. Now, if you admit a difference of somewhat more than 15 per cent., to constitute a very great degree, as most corn-makers would probably deem it, your own paper, I think, has furnished a sufficient number of facts (unless you discredit them,) to conquer your incredulity—at least, as to the twin-corn; for several of your correspondents have stated to you something much more credible than mere "*supposed results.*" But the utmost difference in productiveness you seem willing to admit possible, either between varieties of corn, or of any other plants, is marked by the very qualified and discouraging expression, "*somewhat more productive.*" This indicates so little difference, that were the opinion to become general, it would very soon, I think, effectually prevent all trials whatever between varieties of plants, unless made for some other purpose than to ascertain which would produce most.

In commenting upon Mr. Carmichael's opinion, that more than 15 per cent. difference may be expected from twin-corn in fertile land, you remark, that "this amount of increase, if actually ascertained, is sufficiently great to induce the trial of this corn, on soils recommended as suitable, and in a latitude not very different from that of Queen Ann's county, Md. But this increase is far short of what the sanguine expect; and the writer entirely objects to planting it on any but the very small portion of *rich lands.*" Now, I do not thus understand him; for his words, as you give them, are—"my experience induces me to think, that no great advantage is derived if this corn is planted on lands naturally poor, or exhausted by cultivation." This certainly admits *some advantage*, even on such lands, and is very different from an entire objection; although to plant any one thing in preference to another, in a naturally poor or exhausted soil, would hardly be deemed of much advantage by any one who had ever tried, even without Mr. Carmichael's caution. What "the sanguine may expect" from cultivating the twin-corn, I have no means of knowing; but I can very confidently assert, that there is no authority, either in print or manuscript—at least none that I have ever seen or heard of—to justify them in expecting much, if any more, than Mr. Carmichael has stated.

In the first part of your remark just quoted, you speak of "*latitude,*" as the chief circumstance to be regarded in choosing among the varieties of corn; and in a few lines below you add: "This corn is a *forward* kind, even in Maryland—of course, it is too forward for our location." Of its forwardness, I can assert, from three years' trial, that the difference in comparison with our common corn, does not exceed ten or twelve days; and in regard to your conclusion, that it is "too forward for our location," I must call it a *non sequitur;* at least, if the opinion of Monsieur de Candolle, one of the greatest botanists who ever lived, be correct. This gentleman spent six entire years in prosecuting, through the different departments of France, such investigations as were calculated to determine, with all attainable precision, the general laws by which the geography of plants is regulated. The very numerous facts collected by him during this highly interesting research, proved conclusively, *that although temperature, arising from climate or elevation, light, moisture and aspect, exercise each a considerable influence over the growth and productiveness of vegetables, the distribution of heat,* in the different seasons of the year, *has more power than any other cause whatever.* Now, here is an opinion opposed to yours, and founded on a multitude of facts which the author was six whole years in collecting—confirmed, too, by the general fact known to us all, that in European latitudes corresponding with ours, many plants grow in the open air, which here require the protection of green-houses for more than half the year. On the other hand, your opinion as to the effect of much less than two degrees difference of latitude, (for the middle of Virginia is in 38°, the middle of Maryland in 39°,) is unsustained by any facts or experiments whatever—at least you mention none. But as a farther proof that the twin-corn is *not too forward* for our location, I have authentic information from several gentlemen residing in different and distant parts of our state, (one as far south as Mecklenburg,) who speak very favorably of this corn in comparison with all the other varieties which they have heretofore tried. The only gainsayer whom I have seen in print, is your correspondent, Mr. Andrew Nicol, who has gone so far as to say —"*the bread made from it appears to me less sweet, also drier and harsher to the taste, than that made from our common corn;*" and this, too, in addition to condemning it as less productive than the common corn of his neighborhood. Upon this anathema against twin-corn bread, it has been remarked, that "Mr. Nicol's mouth must have got most marvellously out of taste, when he uttered this sentence." But I, who have always maintained both the truth and justice of the old adage, "*de gustibus nil disputandum,*" have insisted on his right to avow any taste he pleases, notwithstanding, in this case, it is unique, and directly opposed to that of some hundreds of persons, who have declared that twin-corn made the best and sweetest bread they ever ate.

Having at last reached a kind of resting-place in my voluntary and unsolicited labors, I have deemed it best to look back before I proceed farther. This retrospect has elicited a "thinks I to myself," how friend Ruffin and my other readers, (should I get any,) chuckle and exclaim—"what a self-comforting side our friend J. M. G. has given himself on his twin-corn hobby, flattering himself all the while, credulous soul! that he is edifying *us*, rather than gratifying his *own passion* for prosing, in which he indulges somewhat too freely, although we are willing to allow him good motives." I have a strong presentiment that some such reflections will certainly be made, although they may not possibly find utterance in words. Yet, notwithstanding I may increase the risk of exciting a laugh against myself, I must add a few more words in explanation of what I have written.

The facts stated in regard to twin-corn, and the conclusions I have drawn from them, are applicable to every variety of cultivated plant; and my only reason for confining them to one variety of a particular species, is, that I have made more experiments with *that* than with any other. I have *no pets* among any of them; my sole object being to ascertain, as far as I can, which are best in every respect to promote human comfort and general prosperity. As a proof of it in regard to corn, I am now making an experiment with six varieties; and should the twin-corn prove best, it certainly shall not be, from the least imaginable advantage derived from my management of the trial, which shall be as fair as I can possibly make it. But to proceed with my explanations. When I read your excellent article on agricultural hobbies and humbugs, of which I think precisely as you do, it seemed to me that you had gone so far in denouncing and ridiculing them, as probably to discourage all experiments made to ascertain the comparative superiority of the different varieties of plants of the same species. I therefore deemed it important to our cause, at least to endeavor to qualify, in some degree, your general denunciation, and to prove, as far as I could, not only that *all* plants heretofore tried, might be greatly improved in almost every respect, by the careful selection of their seed, but that there was so great a natural difference in productiveness between the different varieties of the same species, as to make it a matter of great importance to ascertain how far that difference might be augmented. If *you*, my good friend, are right, none but the over-sanguine will ever make experiments of any kind on this highly interesting subject. But should the doctrine *I* maintain be right, although hundreds and thousands of hobbies be mounted and broken down in the pursuit, yet, should a few only prove sound, they may amply remunerate both their riders and the public, for all the losses from the hobby-horsical experiments that fail.

It has been said that great inventors seldom become rich; but may not that enthusiasm which is so essential to success in prosecuting useful inventions, and which is the only quality strong enough to combat the ridicule always directed against every thing new, be incompatible with such a degree of economy as would enable them to accumulate wealth? Such, I am persuaded, is the fact; and that the money-making and saving talent is quite a different sort of thing from *that* which has so eminently distinguished the most remarkable inventors among mankind: *so different indeed*, as never to be found in the same individual. The hobby of the *one* is *money—money—money, for its own dear sake;* the hobby of the other, something that will hand down his name to the latest posterity, as entitled to rank among the benefactors of mankind. *His* passion is social, philanthropic, coextensive with the wants of his species; the passion of *the other*, begins and ends in self—self—self. If any great inventor has ever grown rich, I have never seen nor heard of him. But if this be true, some portion of what may be called *the hobby-horsical organ*, (if the craniologists will pardon my infringing their right to christen all the imaginary divisions and subdivisions of our skulls,) although too often injurious to the individuals whose noddles are bumpified by it, is quite as beneficial, upon the whole, to the general interests of agriculture, as it can be to the general interests of any other class whatever. *Ergo*, hobby-horses and hobby-horse-riders, are very useful things in a general point of view, although many of both may be often rendered worthless—the riders too much *galled* to ride any more, and the horses become utterly good for nothing by splints, spavins, ring-bone, and foundering, both in the legs and chest. The latter kind of foundering, if by *chest* be meant the *money-chest*, is so utterly ruinous to our class, that the fear of it too often deters all the half-way experimenters from attempting *any thing*, while it furnishes the "*good-enoughs*" with an everlasting pretext for attempting *nothing*.

The two positions I have sought to establish, which I understand you deny, are, first, that *all* plants heretofore cultivated, in any kind of soil or climate, wherein they will apparently flourish, are improvable, to a great degree, simply by regarding, in the selection of seed, the circumstances which you appear to think of little or no importance. Secondly—that among the varieties of the same species of plants, there is *naturally* a great difference in productiveness, which an all-bounteous Creator has enabled man to make still greater by judicious selection and culture. The universal practice of those who save seed either to sell, or solely for their own use, would seem to sanction my first position, although I admit there are many exceptions to the old saying, that "*what every one says must be true.*" But there is something more than mere practice in favor of this position. We have the testimony of very many credible persons, that they have much increased their crops, especially of corn, by always selecting their seed from stalks of the same variety which produced the greatest number of ears. Three of these individuals I know personally, and a fourth, Mr. Joseph Cowper of New Jersey, is known by reputation to all the reading agriculturists of the United States. Now, these persons did not state it as *mere matter of opinion*, but of *actual experience* during several years' experiments; and I have been willing to believe them; not only because my own experience confirms theirs, but because they ask no money for their disclosures on the subject; and that being the case, could have had no possible motive for humbugging their fellow-citizens.

My second position has in its favor, not only the testimony of many such men as your intelligent correspondent, Mr. Carmichael of St. Mary's, Maryland, but ocular demonstration for all who are willing to sacrifice their hobbies of opinion to visual evidence. For instance, no man can look through an apple-orchard in full bearing, without being forcibly struck with the very great difference in productiveness between the different varieties of apple, amounting often to nearly double. A similar difference may be noticed among several varieties of other fruits and vegetables, all going to prove that there *is* so great a natural superiority in productiveness among them, as to render it a matter of very great importance to those who cultivate them, either for use or sale, that they should choose among the grains, at least, only those varieties which produce most. To ascertain this, as I before remarked, is richly worth the breaking down of ten times as many hobbies, as the most fanciful and sanguine of all our hobby-horsical brethren put together have ever taken into training, from the days of Trismegistus to the present time. If I am right in my estimate of our state character, hobby-horsical planters and farmers are nearly as scarce with us as hen's teeth. The passion which makes such equestrians, is not among the besetting sins of the ancient dominion folks. *They* answer much better John Randolph's graphic description of them, who compared them to terrapins that would never move, after drawing their heads within their shells, until they felt the fire on their backs. In most matters, but especially in all that relate to husbandry, we want, *not the check-rein*, but *the spur and the lash;* not sedative, but *highly stimulating medicine;* if mental stimuli can properly be compared to corporeal, and the former can be both prepared and administered to us far more easily than many imagine. You have only to call us "*the sovereign people;*" to translate for us the old Latin blasphemy, "*vox populi est vox Dei;*" to swear, at the same time, that it is literally true, and you may lead us "into the cannon's mouth." Then huzza! for us Virginia boys: who but *we!* although we may actually have sunk ourselves by our supineness as to all state concerns, and other political sins, to the very lowest grade in our great confederacy. But throw cold water on us, especially on *us* of the agricultural brotherhood, who are as cold generally as frogs, and you level us nearly to the "*caput mortuum*" of earth, into which, alas! our own prodigal waste and abuse of nature's bounties has converted a very large portion of the arable lands of our native state. Rely upon it, my good friend, that we Virginia agriculturists want, most grievously, all sorts of legitimate mental excitement, that can be applied with the least probability of success in promoting our cause. We have always too little, rather than too much steam, *party politics* always excepted. Our danger, meaning thereby the danger of our class, is caused by *too much* torpor; too much of *the good-enough malady*, and not by *the hobby-horsical extreme.* Pardon me, therefore, for saying, that you appear to me inclined to use the lancet, and its almost inseparable companion, calomel, (if such a figure be allowable,) somewhat more than is good for us. We of the clod-hopping genus have had quite enough, and to spare, of *depletion*, in all the modes wherein empiricism could injure us, either in religion, morals, politics, or husbandry—nay, in *body, and soul, and estate;* and what we most want now, is an abundance of that good old-fashioned sort of thing called *kitchen-physic.* But to procure it, although it be the staff of life, we, the said clodhoppers, require the excitement of censure and ridicule, for our numerous sins of omission, with unceasing commendations and praise, for every evidence of an inclination to quit the old beaten track, in which so many of us have nearly starved, for the purpose of trying, so far as our means will justify, all well-authenticated experiments that hold out a tolerably fair prospect of bettering our fortunes. Be it well understood, however, that I utterly exclude all *humbugs*, properly so called, from even the slightest claim to toleration. In plain English, they are, on the part of the contrivers, downright frauds to cheat the ignorant and credulous out of their money; and most heartily will I join you in a war of extermination against them, fearful as the odds may be against us. But for the hobby-riders, one and all, much as I often join in the laugh against them, I confess my sympathy is "pretty considerable," as brother Jonathan says. For this, *you* probably, as well as *some* of my other readers, will think I have good cause, if near relations ought to sympathise with each other. Be this, however, as it may, there is certainly more color of excuse for those poor fellows in Virginia, than in any other state in the Union: for *our* agriculture is literally "*sick almost unto death;*" and you know that "a willingness, nay, an anxious desire, to be cured of any dangerous and alarming disease, is perfectly natural; and the danger usually leads those who are threatened by it, to catch at all sorts of proposed remedies."

Thus endeth my long, and I fear, tedious homily, in regard to which, let me conclude by begging you to correct me, if I have so far misunderstood your opinions as to misrepresent them. Should we really differ materially, and any good to our cause grow out of the public expression of that difference, I confidently trust that neither of us will feel any such foolish pride of opinion as will prevent him from heartily rejoicing at the general result, even should the verdict of our brethren be given against him. Discussion, full, free and friendly discussion, of all important agricultural subjects, and willing, unprejudiced readers, are what our cause in Virginia most grievously wants; for our everlasting political party quarrels have nearly banished the language of gentlemen from all argument, whether oral or printed; while to read any thing in relation to husbandry, is deemed such up-hill work, such a waste of time, by most of our brethren, that all imaginable pains should be taken to change, if possible, so paralyzing, so stultifying a habit. That your highly laudable efforts to do it may be crowned with entire success, is the constant and earnest wish of

Your old friend and fellow-laborer,

J. M. G.

REPLY TO THE FOREGOING, AND SOME OTHER OBJECTIONS.

We have been singularly unfortunate in conveying the meaning designed in some of the passages of the article commented on above; which appears, not only from some of the objections urged by our present correspondent, but from several others. This misapprehension is doubtless caused by the hasty and careless mode of expression used; and therefore we readily lay the blame at our own door. But, the general positions there assumed, (and by which the words of particular illustrations and examples should be construed,) still seem, to our understanding, so plain, that we fear that any additional explanation will scarcely dispel the existing obscurity. To avoid repetition now, we would request of readers to refer to the article in question, (especially the portion on pages 48 and 49,) for examination of the grounds assumed or denied.

We were far from meaning to deny the importance to the product of crops, of a *proper* selection of seeds. On the contrary, (putting aside many and strong expressions of ours in other editorial articles, which we cannot expect readers to remember,) in this piece in question, the advantage of such selection is fully and directly admitted in particular passages, as well as fairly to be inferred from the general context. It is there said, that "it is highly important to adapt the kind of seed to the soil, climate and usual seasons; and the *want of such adaptation may reduce a crop to less than half of what might have been obtained from other seed.*" This surely was saying, though generally and indirectly, yet strongly and explicitly, that by a proper choice of seed, a crop may be, in some cases, even doubled in amount. This greater productive power of one variety of a particular grain over another, was ascribed, not to qualities such as are usually recommended, and sought for in "hobbies," or new pet grains, but to the suitableness of the plant to the circumstances under which it is to be placed, and its fitness, from any peculiarity of character, to resist the disasters to which the crop is to be particularly exposed. "But," continues the passage, "we have not the slightest faith in any of the many prevailing opinions, that larger crops are to be obtained by choosing seed *on account of the form, size, or number of grains, or the size or number of ears, &c.*" In this last position, only as we understand, and according to the meaning before intended to be conveyed, we are directly opposed to our friend and correspondent J. M. G.; and it is a question to be settled not by argument, but by proper, varied, and sufficient experiments; and we are willing to abide by that test, when enough of such experiments are reported.

As all the particular objections are embraced in the general disclaimer just made of denying the efficacy and profit of proper selections of seeds, it is unnecessary to reply to them separately and in detail. One only will be mentioned, because it is founded on another misapprehension of our meaning. This is our inferred "apparent preference for corn with the largest cobs." If any such ground for preference had been expressed, it would have been obnoxious to much stronger objection than what is urged by our correspondent; for it would have been directly opposed to the general principle which we had assumed as correct. We were quoting the opinions and grounds of preferences of others, and accompanied with intimations of dissent, if not of derision, on our part. The "mathematical truth," also, in regard to which we differ, (and mathematical truths, real or supposed, rarely permit a difference in argument,) was stated simply as an illustration of Col. Taylor's ground of choice. Also, in stating a mathematical truth, we ought to have been more strict in terms and definitions; and for want of that strictness of language, our correspondent has certainly succeeded in picking a hole in our "mathematical truth." While admitting, and submitting to the correction, we beg leave to supply the omission of what was meant to be affirmed of ears of corn, and to repeat, that it "is evidently and mathematically true, that if the grains are of equal size, [*and also of like form,*] there will be more of them encircling a large than a small cob."

Another correspondent, in number 3, (at page 178) supposes that we meant to class the ruta-baga, or Swedish turnips, among the family of humbugs. Not so, by any means. On the contrary, they were spoken of as long known in England and "valued for their real advantages," and treated of in English books, before introduced in this country as "Russian turnips," and spread as a novel product of rare and superlative value. This introduction, and the means used to recommend and extend the general culture, was a humbug, though the plant is highly valuable, and its culture profitable, in all suitable climates and circumstances. As fanaticism and quackery are often exercised in the spreading, or ostensible design of spreading, the beneficial influence of true religion and morals, so the true doctrines and valuable products of agriculture may be so recommended by interested falsehood, so as to become humbugs, in the light in which they were there presented.

Neither was it our design to repress or to moderate the ardor of any to try new things. Precisely the contrary was stated expressly, and fair trials strongly recommended.

Still less did we intend to denounce as humbugs the act of *hobby-riding*, or to cast any censure on the enthusiastic individuals who form that class. As our friend J. M. G. intimates, we are among the last who have any right to undervalue that class, of which both he and ourselves have long been, and will doubtless always continue to be members. But though there is nothing to censure, and much to approve, and for the community to be grateful for, in the acts of the riders of hobbies, still it must be admitted that there is also much of extravagance to laugh at; and as we are willing to bear our share of this infliction from others, we have considered that we had a good right to laugh at the follies of some of our brotherhood in return; still claiming for the whole class, and valuing not slightly our own share of the claim, that sanguine experimenters, or hobby-riders, are among the benefactors of mankind, and generally to their own loss, even in their successful labors. Our censure was not thrown on the riders, but upon the grooms and jockies who trained and brought out the steeds, to serve their own interested purposes.

We have to add a word in defence of an expression, not of our own, but of a correspondent whose statements are entitled to high respect. This is the opinion that the bread made of the twin-corn was not so palatable as that of our common corn. This opinion may be correct; or precisely the reverse of it, as stated by our correspondent, may be true. It is a matter of taste, which is not to be settled by argument or evidence. But without joining in this opinion, we know the fact that this supposed inferiority of the twin-corn has been charged by another individual, who did not know of any such opinion having been previously expressed. For our own part, we believe that there is no material difference; as none was perceived, when we changed, without knowing it, from using the bread of one kind to that of the other corn.

ED. FAR. REG.

From the Genesee Farmer.

QUALITY OF MILK.

Further experiments appear to be needed relative to the quality of milk, for the different purposes of cheese and butter-making. It is well known that the *quantity* of milk alone, yielded by a cow, is not a sufficient test of her excellence. The *quality* is of such importance, that many animals furnishing but comparatively little, are, on account of its richness, truly valuable. The following extract from Moubray may serve well to introduce this subject to the attention of farmers, and to throw some light upon it. It is an account of the product of one cow, for one year, and shows in a strong point of view, the superiority of the milk over that of our common animals. This cow was of the Sussex breed.

"Mr. Cramp's cow was seven years old, had produced five calves, and had been two years in his possession. She was fed in *summer* on clover, rye-grass, lucern, and carrots, three or four times a day. In *winter*, with hay, bran, and grains, and often fed, particularly when milking. The manger kept clean, and no sour grains, rotten or mouldy vegetables given, on any account, and the cow never suffered to overcharge her stomach, but to be well filled, and kept with a good healthy appetite. Always when milked, stripped clean to the last drop. Being so well kept, she went dry only seventeen days before calving.

Quantities of milk and butter produced by Mr. Cramp's cow, between April 1807, *and April* 1808.

From 6th to 20th April—milk 8 quarts per day, butter 6lbs. per week. From April 21st to June 2d—milk 22 quarts a day, butter 18 lbs. per week. From June 2d to October 5th, milk 20 quarts per day, butter 16 lbs. per week. From Oct. 6th to November 30th—milk 15 quarts per day, butter 13 lbs. per week. From December 1st to February 8th 1808, milk 13 quarts per day, butter 11 lbs. per week. From February 9th to March 14th—milk 10 quarts per day, butter 8 lbs. per week. From March 15th to April 4th—milk 7 quarts per day, butter 5 lbs. per week,—dry for calving.

Sale of the year's produce and expenses.

	£	s.	d.
Sale of calf 14 days old—butter at 1s. 4*d*.—skim milk at 1*d* per quart—dung, valued at £3, in all, - - - -	76	7	3
Total expenses, including £1 5s. for 10 sacks malt combs, and a farrier's bill 12s. 6*d*. - - - - - -	24	14	3
A year's net profit on a single cow,	£51	13	0"

It will be perceived that the quantity of milk yielded by the above-mentioned cow did not much exceed some of the best of our common animals, but in the quantity of butter she greatly surpassed them.

The following remarks by John Hare Powell, published some years since, on the qualities of the improved short horns, furnish some hints on a branch of this subject, which is of great importance, but has been hitherto but little investigated. In allusion to a sale of some of these celebrated cattle he says,

"There are about twenty or thirty head of the full blood, besides nearly as many of the common and mixed blood. Among the former is the celebrated Bellina, the famous butter cow. In her appearance, she is far below many of her companions, though when critically examined her *points* are all good. The straight back—the perfect level of the spinal column from the horns to the tail,—the square sides, the wide hips, the full brisket, the intelligent countenance, and wide spreading bag, are all there; *but she makes a pound of butter at every milking*, and hence she has not the sleek fat sides, and the filling up so necessary to a finished and beautiful subject. She illustrates the idea perfectly, which we have so often inculcated, that a deep milker or a great butter yielder cannot easily be kept fat. She illustrates another position we have advanced, that milk from different cows, apparently of equal richness, is very differently constituted. *In some, cheesy matter and whey prevail, in others cheesy matter and oil, and in others oil and whey prevail with but a slight quantity of cheesy matter.* The first is common milk, affording a small quantity of cream, and poor skim milk; the second affords a medium quantity of cream, and makes good cheese, and good skim milk; the last affords a very large quantity of cream, no cheese scarcely, and very poor skim milk—so poor indeed, that it is scarcely fit for use. This latter is the case with Bellina; when her milk has stood the proper length of time, the cream, (the milk being three or four inches deep,) is nearly half an inch thick, *and so firm that it will almost bear lifting like a buckwheat cake*, the skim milk being very inferior. Mrs. Barnitz took about half a pint of her cream in a bowl, and in a few minutes produced six ounces of the finest butter we ever tasted, by simply stirring it with a tea-spoon. The butter-milk produced was less than a small wine glass full, and that quite of a poor quality. This cow, unlike the generality of her breed, has coarse hair, and is of ordinary size, and as before remarked, would be taken for an ordinary animal, except upon critical examination by a very good judge."

To be able to ascertain readily, by simple experiment, the character and quality of milk, would be to dairy farmers of the first importance. It would be bad policy to attempt to make butter from milk affording cheesy matter alone, or to manufacture cheese from milk abounding only in oil. The distinguishing characteristics of milk in relation to these points, whether by specific gravity, color, or other particulars, should claim particular attention.

It has been recommended as the best means of determining easily the richness of milk and the quantity of butter it contains, to fill a number of broad, graduated glass tubes, with milk of different kinds, and after the cream has risen, to observe its relative thickness at the top of each. But this, although ingenious and apparently correct at first glance, has been found fallacious. Neither is the *color* of the milk a true test. A few observations, hastily made last autumn by the writer, prove further experiments necessary. One cow gave from ten to twelve quarts daily; the milk was paler than usual, and the cream lighter colored; but with one exception she was the best butter cow in the yard; the cream, though not equal in thickness on the surface to some, was uncommonly *firm and tenacious*, resembling that described in the last quotation above; leaving but little butter-milk, and apparently consisting almost wholly of butter. She produced from six to seven pounds of excellent butter per week. Another cow yielded milk of a richer yellow, which produced a thicker coat of cream; but this was lighter and more spongy, and a less quantity of butter was afforded.

It would be well worth the time and labor of scientific farmers, who can constantly superintend their dairies in person, to give particular attention to this subject, and to endeavor to ascertain by well conducted and accurate experiments, ready and correct tests for the character of milk, or whether best adapted to cheese or to butter-making, and the quantity of each afforded; and also to determine the best mode of causing their complete separation from the whey. Butter-makers should know the precise temperature needed for the proper separation of cream from milk, and the butter from the cream, and the *time* required for each process to be effected in the best manner. No dairy room should ever be without a thermometer.

Proper and profitable selection and purchase of cows for a dairy, would be greatly facilitated by the knowledge of such tests. A single fact may show in a slight degree, the advantage of selection. Cows were purchased for the farm of the writer, for making butter, and the character of good butter-makers sought, so far as a very imperfect knowledge could direct. The animals were no better in appearance than common, but in less than three months in autumn, during a part of which they had greatly diminished in milk, *four* of them* furnished three hundred pounds of excellent butter. These did not include one of the best butter-makers.

From the Gentleman's Magazine, for 1766.

THE ADVANTAGES OF PEAT-ASHES IN DRESSING LAND, AND THE METHOD OF PREPARING COAL-ASHES FOR THE SAME PURPOSE.

Peat-ashes, properly burnt for a manure, are noble improvers both of corn and grass-land; but the substance from which they should be got, is an under stratum of the peat, where the fibres and roots of the earth, &c. are well decayed. Indeed the very best are procured from the lowest stratum of all. This will yield a large quantity of very strong ashes, in color (when first burnt) like vermilion, and in taste very salt and pungent. Great care and caution should be used in burning these ashes, and also in preserving them afterwards. The method of burning them is much the same as burning charcoal. The peat must be collected into a large heap, and covered so as not to flame out, but suffered to consume slowly, till the whole substance is burnt to an ash. The ashes thus burnt, are held in most esteem; but the peat-ashes burnt in common firing, are, in many places, used for the same purposes, and sold at the same prices.

Peat-ashes are found excellent in sweetening sour meadow-land, destroying rushes, and other bad kinds of grass, and, in their stead, producing great quantities of natural grass.

They burn great quantities of peat-ashes in some parts of Berkshire and Lancashire, and esteem them one of the best dressings for their spring crops.

A very great improvement may likewise be made, and at a moderate expense, with coal-ashes; which, when properly preserved, are also an excellent tillage. The improvement is, putting a bushel of lime, in its hottest state, into every cart-load of coal-ashes, when carried out upon the land; covering it up in the middle of the heap for about 12 hours, till the lime is entirely fallen, and then incorporating them well together, by turning them over two or three times; by which the cinders, or half burnt parts of the coals, which are noxious to the ground, instead of being useful, will be reduced to as fine a powder as the lime itself. The coal-ashes should be carefully kept dry. Coal-ashes, thus prepared, are the quickest breakers and improvers of moorish and benty land.

* One of these yielded *nine* pounds of butter per week. They had common pasture only.

From the Gentleman's Magazine, for 1766.

AN ACCOUNT OF THE INTRODUCTION OF RICE AND TAR INTO OUR COLONIES.

John Houghton, a sensible writer on trade and husbandry, Vol. II. page 298. enumerates the commodities imported into England; among which he mentions rice, and gives the following account of it, probably from the custom-house books or bills of entry.

Rice imported in the year 1694.

From the Straits,	1545 cwt.
From Spain,	120 ditto
From Holland,	330 qrs.

But as he takes no notice of rice from Carolina, it is probable it was not then planted there, which will appear with still stronger evidence by the following account.

In the year 1696, my sagacious friend, Charles Dubois, then treasurer to the East India Company, told me often with pleasure, that he first put the Carolinians on the culture of rice.

He happened one day, in that year, to meet Thomas Marsh, a Carolina merchant, at the coffee-house, to whom he said, I have been thinking, from the situation, nature of the soil, and climate, that rice may be produced to great advantage in Carolina: but, says Marsh, how shall we get some to try? Why, says Dubois, I will inquire for it amongst our India captains. Accordingly, a money-bag full of East India rice was given to Marsh, and he sent it to South Carolina; and in the year 1698, he told his friend Dubois, that it had succeeded very well.

But, from so small an original, it required a long time to spread to advantage; besides, the people being unacquainted with the manner of cultivating rice, many difficulties attended the first planting and preparing it, as a vendible commodity, so that little progress was made for the first nine or ten years, when the quantity produced was not sufficient for home consumption.

About this time, a Portuguese vessel arrived, with slaves from the east, with a considerable quantity of rice, being the ship's provision; this rice the Carolinians gladly took in exchange for a supply of their own produce. This unexpected cargo was distributed, which gave new spirit to the undertaking, but was not sufficient to supply the demand of all those that would have procured it to plant.

Therefore the Assembly of South Carolina, taking into consideration the importance of the culture of rice, very prudently voted a bounty to encourage its importation, that there might be a supply of feed for every undertaker.

My ingenious friend, Tho. Lambol, esq. now living, informs me, that in the year 1704, being then a lad, going to school at some distance from Charles-Town, he took notice of some planters, who were essaying to make rice grow.

In the year 1712, the same gentleman was an apprentice to a principal merchant in Charles-Town, who was appointed public treasurer; and he well remembers that a bounty (granted by the Assembly) was then paid to a captain, who brought in the first cargo of rice, after the bounty was ordered: this cargo came from the Straits, probably from Egypt, or the Milanese.

In the year 1713, another ship arrived, and the captain made the like demand, and received the bounty for bringing a cargo of rice and slaves from Madagascar.

From these particulars it appears, that the progress of raising rice in any considerable quantity, was very slow; and I can find no account of any being exported for the first fifteen years. But it is reasonable to conclude, that after the arrival of these two cargoes of rice, for sowing, the planters were amply furnished, to extend its culture; and being a yearly production, it soon became a staple commodity; it is therefore very probable, that in the years 1715 or 1716, a quantity was raised sufficient for exportation, which continued to increase till the year 1726, and then it became a great article of commerce. For my correspondent, Sam. Eveligh, a merchant residing in Charles-Town, writes to me that, from the year

		Barrels of rice.
1726 to 1727	were exported	40,000
1729 to 1730	exported	41,957
1740 to 1741	exported	80,000
1755 to 1756	exported	60,000
1757 to 1758	exported	67,040
1760 to 1761	exported	100,024
*1761 to 1762	exported	34,972
	half barrels	3,600

The Carolina Gazette of June 12, 1762, says, the crops of rice are so great that we expect to make 150,000 barrels.

I cannot express the satisfaction I feel, in reflecting on the wonderful increase of so valuable a commodity, from so small a beginning, in about, or little more than, half a century.

May 26, 1766. P. COLLINSON.

After having given all the intelligence I could collect relating to the culture of rice, it may not be unacceptable to give some light into the original of tar and pitch in our colonies.

Before this, we were beholden to the northern powers for all the tar and pitch consumed in England, which were imported from Sweden and Norway, and for which vast sums were annually paid.

I was long acquainted with Captain Coram, institutor of the Foundling Hospital, and from him I had the following relation: That he was master of a vessel in the Baltic trade; that great part of his lading was tar and pitch, by which he became acquainted with the value of those commodities. He was much incensed at the extortion of the Swedes and Danes, in raising a barrel of tar to the exhorbitant price of fifty shillings; but as we had then no other markets to go to (for Russia had no ports in the Baltic) we were obliged to give it: but the next voyage he made to Sweden, he took an opportunity to observe their method of making tar and pitch.

He concluded, that there was no way so effectual to bring down the price of those commodities, as by the making them in our own colonies; and as he was fully persuaded of the practicability of it, he determined, next voyage to New England, to make the experiment; it succeeded; and he made the first barrel of tar in the year 1698, and brought it over, to show that it had all the qualities of the Swedish tar. After proper examination of it, its goodness was allowed, and he then petitioned the parliament to promote the making tar and pitch in our colonies, by giving a bounty on their importation.

With this encouragement, tar-making soon spread over the colonies; for my friend Lambol, of South Carolina, writes, that in the year 1704, he well remembers hearing some planters felicitating each other on the easy raising of tar and pitch, *instead of indigo*, which they had attempted unsuccessfully.

This public-spirited man, Captain Coram, happily lived to see his single barrel of tar the original of many thousands annually imported; as well as my benevolent friend, Charles Dubois, who often expressed the pleasure it gave him, that he first advised the culture of rice in Carolina, and that his little bag was the original of many thousands that he saw brought over before he died, which happened in 1740. It is remarkable, that these two valuable articles of commerce were introduced much about the same time. If I am rightly informed the making of indigo was revived very successfully in South Carolina in the year 1740. It is an article of such importance, that it deserves the greatest diligence and attention to make it of the best quality, that we and our colonists may have the benefit, and not our rivals, the French and Spaniards, to whom such great sums were yearly paid, for a commodity that may be so easily raised in our southern provinces; the consumption is so great, that we do not at present import sufficient to supply our wants. As rice seems to be overdone, it is to be hoped, that the planters in Carolina and Georgia will turn their hands more to making indigo, as the demand is so great, and the bounty so encouraging.

After many fruitless attempts, the making potash in our colonies has at last happily succeeded in New England; the first fruits of its produce were sent over in the years 1764 and 1765, which proves so good, that it is said to excel the Russian pot-ash; it will therefore prove a very great advantage to that colony, where returns of their own raising are so much wanted.

* Probably this year they turned their hands to making indigo, of which they made 239,629 pounds.

AGRICULTURAL PAPER IN WISCONSIN.

We received lately the first numbers of a new agricultural paper, published at the unheard-of town of Milwaukee, which is farther north-west (as it would seem from the title,) than the art of spelling has yet travelled. It is called the 'Wisconsin Culturist, and *Gardner's* Magazine.' The No. of April 17, contains the list of prices-current which is copied below entire, as a curiosity. It appears, from this list, that every thing to eat in Milwaukee bears a very high price; but on the other hand, agricultural information rates as low in the market there, as if the editor's and publisher's profits were lower than the wages of common laborers; which, however, is often the case, in places where labor is much cheaper than it is in Milwaukee. This paper (in small quarto,) is published once a month, for $1 a year; and it would be inconceivable how it could be afforded so low, in such a place, if the mystery were not explained by the advertisements showing that the paper is an appendage to a seed-store, and nursery, according to the usage of some other and older parts of our country.

"*Milwaukee price current*, [*April* 17, 1838.]

Beans, white field,	bush.	$3 50 *a*	4 00
Peas, blue imperial marrowfat,	bush.	3 50 *a*	4 00

A NEW WATER-FILTER.

Some six or seven weeks ago, when the water of the Schuylkill was so yellow and turbid, and all the conduits from Fairmount ran discolored streams, the following discovery, which we find in the London Morning Chronicle, would have been a blessing, as it may always be henceforth. A Mr. James Richards, of Dumbleton, writing to the editor, observes: "I have discovered a cheap filter to cleanse river water, which you will oblige me to communicate to the public, as it may be useful to the inhabitants of London, Westminster, and other districts where clean soft water is preferred to dirty or hard water. It is nothing more than a bag made of unbleached calico, in the form of an inverted cone, attached to a small wooden hoop, and in this country called a dropping bag. It is first saturated with water, afterwards pulverised charcoal is thinly spread over the inside of it with a dredging-box used by cooks. At first, a part of the charcoal will pass through the pores of the bag with the water, but by continuing to fill it *full* with the same water, and adding charcoal, in a few minutes it will become as clear as spring-water. To prevent the charcoal being washed from the pores of the bag in filling it, place another bag inside it, and dredge a small quantity of pulverised charcoal into it. The cost of both bags is under one shilling, and the two I send you will cleanse from fifty to sixty gallons daily, if it be supplied with water from a pipe and regulated by a stop-cock, and more in proportion to the size and in number as may be required. I have used these filters the last month, and hope the use of them may add to the comfort of others."

This plan, it will be seen, is extremely simple, and within the means of every citizen. Why should it not be generally adopted in Philadelphia?—*Philadelphia Gazette.*

ON THE SOURCES OF MALARIA, OR AUTUMNAL DISEASES, IN VIRGINIA, AND THE MEANS OF REMEDY AND PREVENTION.

By the Editor.

Throughout the course of publication of the Farmers' Register, it has been one of the main objects of the editor to attract attention to the causes and effects of malaria, or unhealthy marsh-effluvia, and to enforce his views as to the means of restraining or preventing this greatest of the evils under which the eastern half of Virginia suffers. To forward this end, every fit opportunity has been availed of; and the subject has been treated, directly and at length, or incidentally and slightly, in various articles in these volumes. But there has been found but little if any encouragement to persevere in this course. The editor has, alone, and without any certain evidence of approval of his views and his course, and certainly without any practical adoption of his recommendations, labored in this cause, which, to his understanding, demands the support of all, on considerations of economy and agricultural improvement and profit, as well as on the more important grounds of the strength or frailty of the tenure by which the people of half of our entire territory possess and enjoy health, happiness, and even life. It is under such impressions of the high importance of the whole subject, that the readers of this journal are again invited to its consideration; and, probably, for the last time, by the present writer, if there continues to be no more interest excited, and action produced, in regard to the evils existing, and which are multiplied ten-fold in power by the ignorant and careless legislation of this commonwealth.

The views of the writer on this subject were presented generally, and at some length, in an editorial article (pp. 41 to 43) in Vol. V, on the causes of, and means for preventing, the formation and the effects of malaria in eastern Virginia; and also in sundry shorter incidental passages in each of all the volumes, in connexion with articles on marshes, mill-ponds, and canals, &c. &c. But as it would be requiring too much of readers that they should either remember, or carefully refer to these various articles, a general, though slight view of the whole subject will be here presented, sustained by additional facts, which have been recently learned by personal inquiry and observation.

That the common autumnal or bilious diseases of eastern Virginia, and especially of the tide-water portion, which is most subjected to them, are principally caused by the effluvia rising from wet lands, is a matter in which all concur. The general difference between the presence of these disorders, in low, wet, or marshy countries, and their absence, or scarcity, in mountainous and dry regions, is so great, that none can mistake, or differ about, the *general* causes and effects. But from this general opinion, which is true in the main, (though having numerous and important exceptions,) there is deduced the erroneous conclusion, that these opposite general effects produced on health, in extensive regions either generally low and wet, or generally hilly and dry, are produced by these opposite natural features, and cannot be very materially altered by art; as art cannot materially alter the natural character of the land. Or, in other words, that nature has made one great region low and sickly, and another high and healthy; and that man cannot do much to counteract the law of nature in either case. Perhaps none may maintain this position, in argument, without admitting partial exceptions in numerous particular cases and localities. Indeed, every man will say that care may lessen the causes and mitigate the operation of malaria, in a sickly region, or increase both in a healthy one. But, judging from the action of both the people and their laws, which speaks more strongly than words, it may be inferred that it is a general belief that such bendings of nature from her course can be but slight, in particular cases, and scarcely worth estimating on a broad scale, or through an extensive country. In entire conformity with this supposition, it is a notorious fact that very few individuals in Virginia have done any thing considerable, or on system, to protect their dwelling places from malaria; and the government has not only done nothing for general protection, but has actually caused the worst of the existing evils, and is encouraging their continued increase and aggravation, by the fixed legal policy of the country; which permits the raising of mill-ponds, which are productive of little else than malaria and disease; and indirectly, but effectually, forbids the drainage of extensive swamps. The production and deadly effects of malaria, in eastern Virginia, for the greater part, is to be charged, not to the laws of God, but to the laws of man; which, in this respect, operate to put away or sacrifice some of the most precious of God's blessings, offered to all, to gratify the whims, or the blind and often mistaken avarice of a few individuals. There are, doubtless, great *natural* differences as to the sickliness of differently situated regions; as between the low tide-water region of Virginia, the central or hilly, and also the mountainous region. But, in their natural state, before damaged by mill-ponds and other of man's miscalled improvements, the low-country was probably less afflicted by malaria, than the hilly parts now are, or may be rendered by the full extension of these injurious operations of man. This is a matter of mere supposition, and cannot possibly be subjected to the rigid test of proof by known facts. But, from reasoning, and inferences from such facts as are known, it seems most probable that some of the now most sickly counties on tide-water were, at the first settlement of the country, less sickly than the hilly and originally very healthy county of Brunswick, for example, has become in latter years.

Even the very important fact of increased and increasing sickliness in this country, is entirely without support from any known written authority; and the whole subject has been so little examined, or thought of, that to most readers the position here assumed may be entirely new. There are no statistics of health to which we can refer for proof. But general and historical facts, few as they are, if fairly considered, will suffice to place the question beyond dispute.

Before proceeding further in this part of the argument, let me remark, that I am opposed in the outset, and shall be opposed throughout, by the reluctance felt by every individual to believe, or if believing, to admit, that his particular property, or place of residence, is more sickly than others, or has become more so than in former times. This self-delusion, and consequent, though perhaps undesigned effort to deceive others, is almost universal. Each man claims for his own place more healthiness than in truth ought to be admitted; and the combined effect of all these individual claims, is to maintain that the whole country is more healthy than is true, and more so than each individual would have claimed for it, with the exception of his own farm and his own neighborhood. It is against this universal prejudice and obstruction that I have had to contend in seeking for facts, and shall have to contend in argument; and, with such opposition, there is but small hope of maintaining my ground, or producing conviction of the soundness of my views, in the minds of those who have so prejudged the case.

One of the strongest proofs of the greater former healthiness of the low country, was the settlement of our English ancestors having been made and continued at Jamestown. It was on May 13th, when they landed; and now, a residence on that spot, or in that region, continued for five months after that time of the year, would be fatal to half of the strangers from a northern climate, even though provided with all the comforts and necessaries which a long-settled country affords, and all of which the first settlers most deplorably needed. It is true, that for some years after the first settlement, there was much sickness, and numerous deaths; and that in fact the infant colony was more than once on the point of extinction. But these diseases and deaths do not seem, from the direct and the still stronger indirect testimony of history, to have been attributed by the sufferers to an unhealthy location; and there were sufficient other causes for all that was suffered, in the usual and unavoidable privations of the first colonists of a new and savage country, added to the extreme improvidence and mismanagement of these settlers, and their government, as detailed in history. Even after several years had passed, and though cultivating a very fertile soil, and aided by annual supplies of food from England, and with all the resources of trade with the savages, hunting, and fishing, still, want of food was one of the greatest causes of disease and death. Of course, there must have been, under any circumstances, more or less of disease caused by malaria; and although any predisposition to such disease, naturally induced, must have been violently urged to action, and aggravated to ten-fold malignity, by hunger, intemperance, exposure of every kind, depression of spirits, and every other painful emotion of the minds of men in such desperate straits—still, even with all these aids, the prevalence of autumnal diseases, the effect of malaria, was not so conspicuous as to stamp the character of sickliness on the location, nor to induce even the proposition to remove the colony, or afterwards its seat of government, to a much higher or more healthy situation. The unavoidable inference seems to be, that the great sickliness of the early settlers was not attributed by themselves, to the climate. Yet, this was a question on which they could not possibly have been deceived. And even if most others had been deceived, by ignorance, and the want of experience of the effects of malaria, this could not have been the case with Smith, the most efficient director, and the true founder of the colony; who would have known better, not only by his general intelligence, but also by his experience of such effects, gained in his campaigns against the Turks. It may be alledged, that fear of the savages, stronger than the dread of disease, caused the choice of, and after-continuance on, an unhealthy spot, because it was more easily guarded on the land-side, and perfectly accessible to ships. But spots equally favorable for defence, and on deep water, might have been selected at first, much higher up the river; and yet Jamestown and its immediate neighborhood continued to be the chief place in Virginia, after the power of the savages had been crushed, and settlements had been extended to distant and inland places. The proof of my position would be sufficiently proved by any attempt made now to settle Englishmen, just arrived, on the border of almost any of our tide-waters, and especially about the junction of the salt and fresh waters. Several such trials have been made with foreign laborers; but the first autumn was enough to put an end to each experiment, by inflicting so much disease and death as to prevent any of the foreigners remaining through another season, who could possibly move away.

There can be but little doubt also, but there was much less of autumnal diseases, or at least of violent and fatal diseases, before the revolutionary war than now. There was no such thing then, as the healthy residents leaving home in summer, as is so usual now, to spend the sickly season among the mountains, or at the north; nor, does it appear, that there was much suffering for want of such resources, although, the climate must even then have become very far more unhealthy than in the early times of the colony.

Another striking proof of the increased tendency of the country to produce disease, even within the last sixty years, is presented by history, in the circumstances of the occupation of Yorktown by the British army in 1781, and the siege carried on by the American army; and especially in regard to the hastily-levied militia from the mountains, and other high and healthy parts of Virginia. Cornwallis chose his position first in Portsmouth, and afterwards in Yorktown, with a view to health, as well as defence, to await the arrival of reinforcements from New York. His army was concentrated at Yorktown, August 22. Washington reached Williamsburg, September 14, and the American army moved on thence to invest Yorktown, Sept. 30, and the surrender of the British army was made on Oct. 19th. Thus, both armies were exposed to the worst part of the malaria season, and the British army to the whole of it. Among the besiegers, were raw militia just raised for the occasion, from Rockbridge county, (of which portion I have been more particularly informed,) and probably from sundry others of the mountain-counties. There was certainly much sickness, and especially among the British troops; but not more than is usual in camps and especially in besieged camps, suffering all the privations incidental to the confined situation. It does not appear, from the very slight notices in history, that there was more sickness than might have been expected if the same circumstances had occurred in the hilly middle region of Virginia. Yet, if the like circumstances could occur now, it can scarcely be doubted but that every soldier, not already acclimated, and accustomed to malaria, would be made sick; and that probably half of those just brought from breathing the pure mountain-air, would never return home.

Another indirect proof is presented in the great and deplorable decline of most of the lower counties of Virginia in wealth, and in the usual accompaniments of wealth, which formerly made a residence delightful in many neighborhoods in which there is nothing now left to invite any one to remain. It is true that other causes, political and economical, have concurred to produce this result. But the most potent of the several causes, was the slow and silent, but continual and increasing warfare on the health of body and mind, made by the action of malaria. By its operation, when scarcely amounting in effect to positive and known disease, the mind is sickened even more than the body. The buoyant spirits are tamed—energy is relaxed—the keen appetite for enjoyment, (which is the greater part of happiness,) is lost; and the victims of malaria cease to strive, or to enjoy; and either sink into apathy and listlessness, or urged by discontent, more than by any remains of energy, take the final step of emigration to the western wilderness.

But the upper country furnishes still stronger evidence, because of positive and unquestionable facts, to prove an increase of the product and effect of malaria. The hilly country between the falls of the rivers and the nearast mountain-range, with the exception of some comparatively small spots, on swamps and rivers, was formerly as free from this scourge as is now the mountain region. But the number and the extent of the unhealthy places have greatly increased, within the memory of those now living; and some large districts have been, in particular seasons, as subject to bilious diseases, and still more to violent ones, than the tide-water region. Indeed, in very many places, universally believed (unless by the mill-owners,) to be injuriously affected by the neighborhood of mill-ponds, these effects of malaria are of as regular recurrence in autumn, as on places near to any of the marshes of the low country; and are much more dangerous.

The third and highest region seems destined, notwithstanding its better defence in mountain sides and peaks, and the rarity of flat surface on which to form wide and shallow ponds, to take its turn next, as the victim of malaria. Already, in that part of the mountain-region in and about Frederick county, there have been particular autumns which seemed almost pestilential. And though such cases of general and virulent disease are rare, particular cases of autumnal diseases are now frequent in many such places where they were rarely heard of thirty years ago.

These statements may be considered by some as exaggerated or unfounded—and, by others, if admitted to be true, considered as showing the want of both patriotism and policy, in the writer's thus exposing the enormous existing and still growing evils under which the country suffers. In regard to the former point, I admit, in advance, the scarcity of particular and positive facts, to serve as proofs, which is found throughout the whole subject; and that among the existing difficulties of obtaining such facts, (and still more by a single and unaided individual, who has had little opportunity to make proper researches.) I have to rely mostly upon general and loose opinions, and deductions from general facts. Hence, there is much liability of mistake. But if the public can in any way be driven to the examination of this subject, and numerous individuals be excited to search for facts, whether to sustain or to oppose my views, the arrangement and presentation of such facts will serve as materials, which are now almost totally wanting, and will enable this all-important question to be hereafter properly discussed, and correctly determined.

If there were no hope for relief, there would certainly be no use in exposing or dwelling upon these distresses of our people. But, though nothing yet has been done for relief, nor does it seem to have entered the imagination of our legislators—and though all they have yet done has been to add strength to the evil—still it is my confident opinion, that relief may be furnished for this sorest evil of the land, and furnished easily and profitably; and that it is perfectly within the power of man to dry up the most fruitful sources of malaria, and to bring the whole, or very nearly the whole of Virginia, to a state as healthy as that of any other country in the world. If such a result is indeed attainable, it is worth making every possible exertion for; and nothing will induce the smallest exertion, either by the people or the government, except a full exposure of the enormity of the evil which presses upon the country.

It is not my purpose to attempt to investigate the cause and trace the mode of operation of malaria. Though worthy of every care and labor, as a scientific question, it is one which as yet has entirely baffled every attempt at exposition. But though it is as yet unknown what is the chemical character of this subtle fluid, and what are the precise circumstances under which it is evolved, and what is the manner in which it exerts its baneful influence—still the main and most important points admit of no question. Thus, and in general, all persons, from the most ignorant to the most learned, agree that there is *something* which rises into the atmosphere, in hot weather, from marshy ground and stagnant waters, which tends to produce the common autumnal fevers in those who are much exposed to breathing the air contaminated by this admixture.

Though I speak of malaria as an aëriform fluid, or gaseous product, it is not designed to found my argument upon the truth of that opinion. Though, for convenience, as well as because inclining to the belief, malaria is here spoken of as a material aëriform product; yet, it may be also used as a term to designate the particular *condition of circumstances* produced by certain causes, which condition operates to produce and strengthen autumnal diseases. Still less do I mean to maintain that malaria, even if material, is of any one kind of gas, or any particular combination of several kinds. Besides these, there are many other common points on which the learned investigators of malaria totally disagree; and so much does each one insist upon deducing general principles from his own particular facts, (or supposed facts,) and so slightly and incorrectly have such facts been observed, that the general reader becomes lost in the contradictory positions of different instructers. Thus, judging from particular and isolated observations, with some writers, there is no condition of circumstances, which will not sometimes, in a warm climate, produce malaria; and with others, upon equally partial and imperfect observation of other facts, the production is denied to be usually caused by any of the circumstances which are generally deemed the most certain and fruitful sources. One writer, perhaps, has known an exemption from disease in those who lived close to a stinking marsh, or a stagnant pond; and hence he denies that these are sources of malaria, and accordingly searches for them in other circumstances. Another has known the effects of malaria on troops encamped in a high defile in the mountains of Spain, where the soil was dry and stony, and no water except rapidly flowing rivulets, and the place some miles distant from the nearest marsh or lake. Hence he concludes, that even such a locality as this, in certain (unknown) circumstances, throws out abundance of malaria. Considering the circumstances under which most of the works on malaria have been written, it would be strange if they were not quite contradictory. The authors of most of them were army-surgeons and physicians, who observed the effects of malaria, in some deadly region, upon soldiers not at all acclimated. Perhaps the author was confined to a garrison, or at least limited in his observations to the line of march of an invading army; and in a country to which he was totally a stranger, and among a hostile people, whose opinions he could not learn, and whose language he probably did not understand. If a physician of Lord Cornwallis' army, who had merely accompanied his march through Virginia, and been cooped up in Yorktown during the siege, had written a treatise on the diseases of the country, he would have been better prepared to treat of them than most of those who have essayed such tasks; and he probably would have considered as a regular disease of the country the fatal "jail-fever," which swept off in numbers the absconding slaves who had joined the British army, and were crowded together in Yorktown, until the surrender, and which form of disease has never been known there, before, or since.

All agree that decaying and putrefying vegetable matter is one of the greatest, if not the only source of malaria. Of course, then, in addition to the sufficient abundance of the material, the circumstances most conducive to its putrefaction, must be the most favorable to the production of malaria.

The presence of moisture, a certain degree of heat, and the access of air, are circumstances *essential* to fermentation, and of course to the production of malaria; and neither can take place without the aid of all three of these things. Much moisture would be less favorable than a less quantity; and entire covering by water would, by excluding air, prevent fermentation, and its consequence the formation and escape of malaria.

It is also one of the few settled points, among scientific investigators, that malaria is very light, at least when warmed by the sun; and hence the fact known to many in this country, that those who live on the borders of marshes, and of mill-ponds, sometimes escape all injury from their exhalations, when others, who live on high hills, and at much greater distances from the sources, suffer greatly by the disease produced. Facts of this kind are numerous, and of regular annual occurrence, in Gloucester county. The whole of the wide and very level low-grounds furnish residences very healthy, compared to the tide-water region in general; though intersected in every direction by tide-waters, and though there still remains much swamp land unreclaimed, such as the whole body of low-ground was when in a state of nature. But the high, dry and hilly land, which forms the ridge of the county, is less healthy; and the highly elevated and beautiful sites of mansion-houses overlooking the low-grounds, are universally sickly in autumn.

If all the facts in regard to the action of malaria, were as regular and uniform as this one, just stated, is in Gloucester, there would be far less doubt on the subject. It is the uniform character of the country, in its high-land, low-ground, and also the water, and the long extent of each, which causes these effects to be so uniform there. Owing to causes stated in the description of the low-grounds of Gloucester, (page 178,) there is but little malaria evolved there; and if that, as supposed, rises by its greater levity, the regular daily sea-breeze must cause it to float towards the highlands; and the long and regular line of ridge cannot fail to receive it, and in not very different proportions. But in most other situations, even though malaria should be produced in great quantity and with direful effects, yet these effects are so extremely irregular, in the places, the times, and the intensity of their operation, that they cannot be certainly traced to their true source; and therefore, that source may remain scarcely suspected, while it is dealing out death somewhere in almost every season. Away from the vicinity of the sea, nothing can be more irregular than the winds; yet, supposing a mill-pond to produce a regular and large supply of malaria every autumn, (though that supply is itself extremely irregular,) it depends upon the direction, force, and continuance of every change of wind, whether and where, and to what extent, the malaria will produce disease. It is therefore not at all strange, nor opposed, as is thought by some, to the regular annual production of malaria or causes of sickness, by each mill-pond, that the visitations of sickness, at any one place, should be very irregular, and the difference be often totally inexplicable from any known causes, or variation of circumstances.

According to the views presented, there must be more or less malaria (or the gaseous products which, under certain conditions, form malaria,) evolved in every country where there is much vegetable matter to ferment, and sufficient warmth of climate to carry on fermentation. But, in the small quantity which is unavoidably extricated in every such temperate and fertile country, these products seem to be harmless. Perhaps a small quantity is absorbed as food by growing plants, and this aids the production of the earth. If so, this beneficial operation is made easy by another quality of malaria, which is well established as true. This is, that though it is so expanded by the sun as to rise above the lower air, still it remains on the surface of the earth in the night, after being extricated, or perhaps descends again from above, when condensed by the cold night-air, and of course lies in contact, through the night, with growing plants. Hence it is, that sleeping on the ground, or in the lowest apartments, and being exposed to the night-air, invites the attacks, and increases the virulence of malaria; and hence also it is, that the keeping of fires at night, even in warm weather, has been found highly useful to health, in places much subject to autumnal fevers.

Though it may then be theoretically true that every good soil, in every agreeable climate, is throwing out malaria to a certain extent, it is only large quantities that are hurtful; and in practice, we have only, if possible, to avoid the formation of the hurtful excess of the products of fermentation. If, in lower Virginia, we can guard against the existing and increasing excess of malaria, our situation would be one of the healthiest in the world. For while we are comparatively free from the many and fatal disorders of the lungs to which the inhabitants of northern, and what are usually and improperly called *healthy* countries, are peculiarly subject, we have no source of disease peculiar to our location, save this one, which I fully believe, it is within our power to guard against.

Putrefying animal matter, alone, however offensive in scent, is supposed not to produce malaria. It cannot be doubted but that decomposing vegetable matter is its source, because there is no production of it where there is no such material. Still, vegetable matter, alone, or even when mixed with some putrescent animal matter, does not seem generally to produce malaria in great quantity, or with manifestly injurious effects on health. Thus, the gradual fermentation and rotting of the litter in cattle-yards, when left to stand through summer and autumn—or when the same was heaped and so left, (as was formerly the general practice in lower Virginia on all farms where manure was an object of care—) never was known to be certainly and highly injurious to the residents on the farm. Doubtless, malaria, and to an injurious extent, was always thus produced; but I have never known a sensible difference in regard to health, in years when either of the practices above-named were pursued, and when the material was carried out and applied to the fields in the spring, before fermenting. Yet, if judged by the test of some of the causes and effects as described and reasoned from by writers on malaria, one well-filled yard of litter, rotting through summer, ought to have produced enough malaria to kill half the inhabitants of the farm; and effects, in general, which would have been so disastrous, and so sure, as to leave no doubt of the cause of the evils, and of the absolute necessity of preventing the recurrence in future.

But the putrefaction of vegetable matter, mixed with other things, as earth and water, and under peculiar circumstances, (though neither the precise admixture nor the circumstances are known,) produces disease to such extent, that there is no doubting or mistaking the connexion of causes and effects. Such sure and abundant sources of malaria are the following materials. 1st, The putrid and stinking water of stagnant ponds, partially dried by the heat of summer. 2d, The mud bottoms of such ponds, or of streams reduced by drought, rich in decomposed vegetable matter, and left bare of water only in summer. 3d, Fresh-water marshes, of vegetable soil, frequently, but not regularly, covered by the tides. 4th, Fresh-water marshes, laid dry by embankments, and thereby permitted to rot away rapidly. 5th, The meeting of salt and fresh waters on land full of vegetable matter. Of these several and most important sources of malaria, I deem the third (fresh-water marshes in their natural state) to be the least hurtful; and that the sources numbered 1st, 2d, 4th, and 5th, increase in virulence in the order in which they are named. The greater evils produced by the last are universally admitted, but still by an erroneous deduction from the premises. The belt of the tide-water region of Virginia, in which the fresh water flowing down the rivers mingles with the refluent salt water from the ocean, is well known to be more subject to autumnal diseases, than any other extensive space in the country. The breadth of this belt varies much in different seasons. The parts of the rivers in which the fresh and salt waters meet, and where each alternately has possession, as the tide ebbs or flows, may be but a few miles wide, and even that space is not stationary. But if the limits of this belt be fixed by the highest points to which the rivers have been known to be brackish, in driest summers, and by the lowest points where they are fresh in winter, then this belt may be considered for the time as 40 or 50 miles wide, and, in length, stretching across all the tide-waters of the state. But in the much narrower space where this mingling of the salt and fresh waters usually takes place during the heat of summer, malaria acts with most intensity. Hence the general opinion, that it is simply the meeting and mingling of the fresh and salt waters which cause disease. This is not so, or but in a very slight degree. It is either the passage of fresh-water over salt-water marshes, or of salt-water over fresh-water marshes, that causes the great production of malaria, and disease. This is an important distinction, and the truth or error of the position deserves the most careful investigation. If the mere mingling of the waters were the cause of sickliness, any relief for this part of the evil would be hopeless, as the waters *must* meet and mix together, *somewhere*. But if it be as I suppose, the evil may be greatly restrained by works of art, or by simply preventing the unnatural accumulation of vast reservoirs of fresh water in mill-ponds, which when discharged, by breaches in the dams, or by opening the flood-gates, overflow salt-marshes, which the natural or unobstructed stream never could have covered.

Salt-water marshes, not touched by fresh-water streams, are not unhealthy to any considerable extent. This is susceptible of proof by innumerable examples in Virginia on the borders of the ocean, or of the waters of the Chesapeake bay. It is rare, however, to find a large salt-marsh attached to extensive high-land, which is not reached by some small stream; and every salt-marsh of course must sometimes be well washed and freshened by the heaviest falls of rain. Therefore all must, slightly and at some times, be prejudicial to health. These, however, are exceptions of but small practical or sensible operation.

The view here taken of the manner in which malaria is produced most certainly, and acts most injuriously, though not sustained by any known authority in this country, nor by any other precisely as stated here, is not therefore presented as original. I derived it, and thence deduced my application to this country in a modified form, from the interesting report on the malaria of Italy by Gaetano Georgini, of which the substance was published in two different papers in the Farmers' Register, (p. 502 of Vol. IV, and 460 of Vol. V.) In this report the author shows by the most conclusive argument and facts, that the irregular irruptions of sea-water over tracts of marshes, or other low-grounds, of fresh-water alluvial formation, caused the long continued and worst effects of malaria; and that by simply guarding against the entrance of sea-water, the country was restored permanently to healthiness. He says nothing of the reverse operation, the irregular floodings, with fresh-water, of salt-marshes. But what is produced by the one, can scarcely fail to be as well produced in the other case. The *mode* in which the effect is produced is not attempted to be explained by the learned author quoted above; nor does any explanation seem sufficient to my mind. The rapid and abundant production of malaria may perhaps be aided, if not entirely caused, by the luxuriant cover of fresh-water plants, in the one case, being partly killed, and made ready for putrefaction, by being covered by salt water; and in the other case, in this country, by a like injurious operation on the plants peculiar to salt marshes, produced by the overflowing of fresh water. We know that certain plants flourish best in salt and wet soil, as others do in wet soil entirely free from salt; and that respectively with these different growths, the salt and the fresh marshes are heavily covered. It must follow from a sudden change in the condition, from salt to fresh, or the reverse, that the health of the entire growth must be greatly injured, and much of it subjected to death and decay.

The next most fertile source of malaria, (or perhaps what is even of greater malignity, for the small space occupied,) is presented in what is entirely the work of man—the miscalled *improvements* made by embanking and partially or entirely drying tide-marshes. The soils of these marshes, as I have ascertained by careful analyses, are composed, for about half their weight of vegetable matter, and probably nine-tenths of their bulk is of that material, destructible by decomposition, when circumstances are favorable to that result; and drainage and cultivation produce precisely the condition which is most favorable. When covered twice every day by flood-tide, a marsh soil of this kind, though composed of the most putrescent materials, is but little subject to decomposition; because being always thoroughly water-soaked, even when not entirely covered, and by water continually changed, the air is too much excluded, and the wetness is too much in excess, to favor the progress of decomposition. When the marsh rises so high as not to be covered by the daily or frequent tides, then decomposition is more favored by the drier state of the surface, and to a greater extent, malaria is evolved, and health injured. Hence the inference, that the higher and the drier the marsh, the more it is injurious to health. But as soon as such a vegetable and putrescent soil is made nearly dry, and still more when cultivated and exposed to be penetrated by the air, decomposition proceeds under the most favorable circumstances. The soil sinks annually and rapidly, not so much by drying (as commonly supposed,) as by actually rotting away, and in a few years, it is reduced to so low a level, as again necessarily to pass under the dominion and shelter of the water. The more complete the drainage, and the more perfect the management as arable or tilled land, the more rapidly is that end reached. In the progress to this end, a layer of the whole soil, of from one to three feet in thickness, will have passed off into the air in the gaseous products of putrefaction, of which enormous products, a large proportion will be malaria, and the effects produced by it on the health of some of the neighboring population are generally so evident as to leave no doubt of the source of the evil. More full details on the effects of embankments of tide-marshes are to be found in previous articles in this work.*

The production of malaria by the last named operation, the embanking of marshes, however, is necessarily of very limited extent—and moreover of very limited duration. Nature soon asserts and enforces her rights; and the hopes of the improver, and the land so improved, are together overwhelmed by the reinstatement of the waters, and this source of disease is thereby cut off.

Tide-marshes, however extensive and injurious in their operation on health, still are limited to a comparatively small proportion of our broad territory. But there is another source which spreads disease over half the state, and which is entirely of artificial formation, and of which the evil effects have been becoming more and more extensive, and more and more virulent, from the early settlements of the country to this time. This wide-spread and generally operating source of disease and death is furnished by the numerous mill-ponds, of variable height of surface, which are now scattered over the whole face of eastern Virginia, and of which every individual case adds something to the general and enormous amount of injury to health and to life.

The law of Virginia in regard to the erection of mill-ponds, with perhaps the exception of the fence-law, is one of the most stupid, and most regardless both of private rights and general interterests, of all in our code; and it is far more objectionable than the former, inasmuch as while the one merely robs private and destroys public wealth to an enormous amount, the mill-law permits and encourages also the destruction of health and of life throughout the whole land. It is true, unfortunately, that this opinion is not entertained by but few persons: and that even with those who admit that all such mill-ponds are injurious to some extent, their estimate of the amount of evil is much below mine. It is my object, to awaken the community to a sense of the enormity of the evil, and thereby to induce the commencement of measures of remedy and prevention. The universal acquiescence in this policy of our country, and the almost universal ignorance of the evils which it produces, requires strong language to enforce novel views in opposition to long established opinions. But it is confidently believed that my denunciations will be justified by reason and by facts, and by the magnitude of the existing evils.

There has long prevailed in Virginia a mania for building water-mills, which was not restrained by insufficient regular supplies of water to fill the ponds, nor by the insufficient prospect of business and of profit, even if there were no failure of water. In consequence, there have been not only erected mills on every stream barely sufficient to keep a common corn-mill in operation, but also on as many others where the water-power was either insufficient, or totally failed, during the driest season of every year. In the tide-water region, the mills for grinding wheat-flour, or any thing else for sale abroad, are limited to the falls of the large rivers. All the others, (and probably there is on average one for every square of five miles,) are merely designed to grind for toll the corn used for bread in the immediate neighborhood; and, considered merely in regard to money-cost and profit, it is most likely that half the mills in the country do not get enough toll-corn to pay for more that the costs of maintenance and repairs of their establishment. The more worthless the mill, on account of the insufficient supply of water, the more productive it necessarily is of malaria, diseases, and death. It will be difficult for me to make those who are unacquainted with our country believe that hundreds of mills have been built, and that most of them are still kept up, and many more new ones will probably yet be added to the number, which cannot yield any clear profit, above the entire cost, to the owners, independent of cost in property to the neighbors, and the cost (whatever that may be) of health and life to the country at large. Still the fact is notorious throughout lower Virginia, if it does not extend through the higher middle country. The only reason that I can conceive for so many unprofitable investments of this kind, is, that many residents of the country build mills, as many others raise race-horses, more for amusement and excitement, and to vary the monotony of their lives, than for profit. But this propensity of individuals could not have done much mischief to the country at large, but for the encouragement offered by the government. According to the law, and the long-established usage under the law, any man who desires to erect a mill, and for which it is necessary to pond the water on some of his neighbors' land, has nothing to do but to apply for an order of the county-court, by which the sheriff summons a jury to meet on the spot, to judge of, and assess the damages that will be sustained by the owners of the lands designed to be covered by the pond. The jury is generally composed principally of men as ignorant and unfit for such investigations and estimates as the neighborhood can furnish—and they decide by guess as to how much land will be covered, and what damage will be sustained in the loss of the use of the land. There is no question entertained as to whether a mill is at all required by the demand of the neighbors for meal; and if the question of the effect on health is even named, it is addressed to a body entirely unacquainted with, and regardless of the whole subject. In fact the question as to health has rarely been considered in any such cases; and never duly considered. If the land

* See Farmers' Register, p. 107, and 129, Vol. I. and p. 41, 42, Vol. V.

that will be covered by a pond, though very rich, is then in the state of swamp, and totally unproductive, such an uninformed jury, as the case is usually submitted to, will be very ready to decide that such land is worth nothing; and if $3 an acre is given as damages, for the land actually to be covered by the pond, it will be deemed a liberal allowance. The court will rarely refuse to sustain the verdict of the jury.

Though the use of the land thus covered is forever taken from the owner, or, for as long as the mill-owner may choose to keep up his pond, still the right of property is not changed. This small reservation of right, or feeble homage to justice, serves as a still further injury to the community, and is not of the least value to those to whom the right is reserved. It would be far better for all parties, if, when land was thus condemned to be covered by a mill-pond, that the damages assessed, however low and pitiful compared to the damages actually sustained, should have been deemed the purchase-money of the land, and the absolute right of property vested in the mill-owner. If this were the case now, there are many mill-ponds in Virginia which would be forthwith laid dry, even though the mills should necessarily go down; because the land covered by the ponds is now known to be worth more for cultivation than the mill is for toll. Hundreds of other mills, of greater profit and value, also, in that case, would be better supplied with water by canals than by their present ponds, by which their value as mills would be increased, to the owners and to the public, and the nuisances of the ponds be equally abated. But as the law now stands, if a mill, which will not bring in of net rent $50 a year, covers by its pond 500 acres of rich land belonging to other persons, the mill-owner has no interest whatever in draining the pond, because its drained bottom would belong to other persons. In any case approaching to this, and in which there would be a gain to all the individuals concerned, by draining the pond, still it is not done, and the nuisance continues long after it is well known to be such, because there is a contest between the several owners of the pond and of the land covered by it, in regard to their respective shares of profit to be gained by emptying the pond. Many such cases still exist in Virginia; although many of the most unprofitable ponds, from proper views of economy, have been drained, and either substituted by cheaper and more efficient canals, or the mills put down entirely. An old mill-pond in Dinwiddie county, which covered 1200 acres of land, has been drawn off, and thereby an indifferent mill exchanged for a large fertile farm. This would not have been done, even if the mill was worthless, but for the ownership of the mill, and the land covered by the pond, falling into the same hands. There is a mill-pond now kept up in Prince George county, which is supposed to cover nearly 400 acres of land; and there are many others not much smaller, on different branches of swamps in lower Virginia. The larger the pond, in general, the greater proportion of bottom is left dry in autumn, and the more disease is therefore produced; and though the draining of such large ponds would be so much the more an object of gain, there is the less chance for its being done, because of the separate ownerships and interests.

Almost all the mills throughout the lower part of Virginia, and also a large proportion of those in the more hilly middle country, are worked by streams which are inadequate to the daily supply of the mill, and evaporation from the pond, even if the grinding is not necessarily suspended or diminished at any time. To guard against the temporary failure in dry weather, the full "head" of the pond, (or the level of water for which damages were assessed, and to which the water may lawfully be raised,) is much higher than the lowest level that will work the mill. The land covered is also usually very nearly level, so that to raise the water 10 or 15 feet at the dam, will often back the water from one to two miles up the low-grounds. If the variation between a full head of water, and the lowest level, be 5 feet perpendicular, it will often cause the uncovering of many acres of the bottom of the pond to the hot sun, and thereby furnish a most fruitful source of malaria in every such case. Rich alluvial mud, as this always is, thus exposed, in hot weather cannot be otherwise than very injurious to health; and there is not a pond-mill in Virginia, with a variable head, which has not more or less of the pond every summer thus converted to a fruitful seed-bed and nursery of disease.

Besides this, there is the not rare occurrence of the pond being entirely drawn off in summer, by the breaking of the dam, and suffered so to remain for weeks or months, before being again repaired and filled. In this case, a double quantity of bottom is exposed to putrefaction, and fitted for the discharge of unhealthy miasma.

At all times, in ponds supplied by streams as feeble as most of those used for mills in Virginia, the water approaches to a stagnant state; and therefore, of itself is a producer of malaria. In dry seasons, when unusually low, the putridity of the water of such ponds is perceptible to the sense of smell; and it must be then far from harmless.

Another, and in certain situations, the greatest evil of mill-ponds, remains to be stated. The others above-mentioned are the effects of the scarcity of the supply of water; this is from the excess, which is found in all streams, at some times, even though the most deficient at others.

To guard as much as possible against the expected scarcity of water, the mill-owner aims to hold, when rains increase the usual supply, as "full a head" as he has a right to maintain. When this supply is exceeded, as it frequently is, and greatly, if the dam is not actually broken, and the whole emptied, in one prodigious flood, at least the flood-gates are opened widely, and a discharge made ten-fold greater than would have occurred, during equal time, if the stream had not been obstructed by a dam, and had discharged as regularly as the supply was increased. It will be evident, on considering these circumstances, that water from a mill-pond, whether discharged by flood-gates, or otherwise, must be far more variable in height, and in extent of inundation on the land below, than the natural stream, unobstructed by art; and still more than the stream opened and improved, and its course facilitated by art. An ordinary natural stream, which might have a very uniform discharge in dry weather, and would rarely overflow its banks in wet, if dammed across for a mill, would often have its bed, below the dam, left almost dry; and at rare and irregular times, would be converted to a tremendous flood, which would sweep over many hundreds of acres more than the floods of the natural stream could have reached. Besides the immense damage caused to cultivated land by these floods, (and which kind of damage is rarely estimated or thought of by juries, when mills are established above,) there are numerous hollows made, and filled with water, which, on the retreat of the flood, (as hasty as its inroad,) remain so many stagnant pools, until made dry by evaporation. The whole land, thus covered, is saturated with water; and, from the nature of the rich alluvial soil, is throughout, as it dries, made a producer of malaria.

But the worst part of this evil, by far, is when these artificial floods of fresh-water pass over salt-marshes—which happens in all the country in which the fresh and salt waters meet; and this combination of causes I consider the most efficient producer of disease in that part of the country, and the thing which ought most especially to be guarded against. According to the views before presented, the passage of fresh water over salt-marshes, no matter to what extent, is one of the most sure producers of malaria, and of a particularly malignant kind. The mill-ponds, alone, form other and far more extensive, if weaker sources of the poison; and by the union of the two, the mill-ponds exert all their usual bad influence above the dams, and spread ten-fold more pestilential effects below, by inundating the wide salt-marshes, which by natural streams would scarcely have been affected.

On Nansemond river there are lands already rich, and having inexhaustible supplies of the best marl, which have been sold at $10 the acre. There are hundreds of estates in the same belt of country, which cannot be sold for as much as the cost and present value of the buildings. And this otherwise fine country, so accursed by disease, owes its condition principally to the streams which flow into the salt tide-waters, and which are so numerous, and their sources so interlocked, that there is no spot safe, by remoteness of position, from these combined effects of mill-ponds and salt-marshes. It is therefore sufficiently evident why that otherwise finest part of the state, for agricultural improvement and profit, should stand among the lowest in both these respects. Yet this part of Virginia might be rendered both healthful and fruitful, and the delightful region which God has permitted it to be made, if man would accept and avail of his bounties, by merely using half the expense for improving, which has been lavished to inflict pestilence and poverty on the country.

These statements and expressions of opinion will be unpalatable, if not offensive; and perhaps may subject the writer to the charge of being willing to injure the residents of the region for whose relief in this respect he is most anxious, and of the facility and cheapness of obtaining relief, by the use of proper means, he feels most confident. If the exposure and probing of the ulcer be never so painful, let it be remembered that it is done solely for the purpose of seeking for, and applying, a sure remedy.

There is still another source of malaria, which it is necessary to touch on in connexion with the above-mentioned, though it has been already treated more fully elsewhere, and therefore will be but slightly mentioned here.*

From the vegetable matter upon the driest land, as it ferments and decays, there must be extricated more or less of the gaseous matter, which, when in excess, is injurious to health. According to this view, the whole surface of the country, and especially that most heavily covered with vegetable matter, may furnish malaria. The degree of hurtfulness of this product will depend on the power of growing vegetables to feed on, and of the soil to absorb and fix in it, this matter, which, according to its direction and quantity, may either enrich land, feed plants, or poison men. In earlier publications I have stated at large my reasons for believing that all the products of vegetable decomposition, on naturally poor lands, are lost to the land;† and as the ultimate results of decomposition are gaseous, or aëriform, they must go off into the air. These products constitute or cause malaria, and its injurious effects on the health of the inhabitants. But calcareous matter serves effectually to fix there the enriching principles of decaying vegetable matter, until they become the food of growing plants. Hence the deduction that a naturally poor soil, made calcareous, will no longer throw off gaseous products, or malaria, into the air; but will store it up as fertilizing manure. The sure remedy for the irregular and generally slight degree of sickliness thus caused, is, to marl or lime all the land that requires calcareous earth. But that remedy would not be sufficient, if mill-ponds or marshes in the neighborhood continued to send out large additional supplies of the aëriform poison.†

The correctness of my deductions as to the very injurious effects of mill-ponds on health, will be denied on several grounds, which, so far as expected, I will anticipate as objections, and state with the answers, as follows:

Objection 1. Admitting generally, and to some extent, the ill effects of mill-ponds in producing noxious exhalations, and autumnal diseases, it does not appear, that these effects can be either so great, or so sure, as is charged above. The residents on the farms nearest to mill-ponds are not always, and often not at all, more sickly than those who reside several miles distant. The house of the slave who acts as miller, is usually near the mill, and close to the pond; yet families so situated are generally as healthy as any others, and sometimes are healthy in a remarkable degree, compared to the neighborhood generally.

Answer. Near the mill-dam, or the lower end of the pond, may well be less affected by the exhalations from it, than places a mile or two more distant. That part is the deepest of the pond, and of which also the banks are steepest; and perhaps half a mile in length of the bottom of the upper and shallowest part of the pond, and of alluvial mud, might be left naked in drought, before a margin of steep hill-side, of three feet width, could be exposed near the mill. Further—from the greater lightness of the malaria, it will rise high in the air, and would soon be carried far away by a moderate breeze. If the wind be moderate, and steady to

* See "Essay on Calcareous Manures," 2d ed., chap. xix., and "Essay on the Police of Health," commencing p. 154, Vol. V. of Farmers' Register.

† Essay on Calc. Man., ch. iii., viii., and xii.

one direction, and still more if its course be confined to an opening by or between woods, or to a narrow valley between high hills, it may well be imagined that the poisonous air might injuriously affect persons perhaps five miles from the pond, and who would not suspect the operation of so distant a source; while others, close to its border, but in a different direction, or on a different level, might escape its influence.

Objection 2.—There is not enough difference in the usual or average healthiness of families the most exposed, and others the least exposed to mill-ponds, to attribute much of the effects to these causes. Whole neighborhoods, in some autumns, are very healthy, and in others very sickly, without either condition seeming to be connected with any certain and known state of the nearest mill-ponds.

Answer.—The extreme lightness of the poisonous air, and great and frequent variations in the direction, force, and continuance of the winds on which it is borne, make it generally impossible for it to be known from which particular pond or ponds the malaria rises, or where it is carried. It is most probable that the exhalations of twenty ponds, of which the most remote may be thirty miles apart, may be mingled together, even by the winds of a single day, and thus combine and average the effects of all. Further—if all the mill-ponds of a county furnish one half of the active and injurious malaria, and the other half is thrown off, nearly equally, by the whole surface of the land, (though some parts would receive the strongest doses, and others escape with having only the weakest,) it would be impossible to understand the mode, and estimate the intensity, of operation of the known general causes; or to refer, with certainty, any one effect to its special or principal cause. Thus, a farm, relieved from all malaria of its own product, by marling and by drying its mill-pond, though evidently showing the benefit in increased general healthiness, might still be sorely visited by the seeds of disease from other and remote sources, directed and concentrated by a steady wind.

Having presented these views of the origin, action and effects of malaria in this country, I can better exhibit the progress of the causes which I believe to have operated, and which are still continuing to operate, to produce the change from a healthy, to an unhealthy state.

When our ancestors first reached this shore, nearly the whole country was in a state of nature. The savages had cleared for cultivation but a few fertile spots on the banks of the rivers; all the rest of the land was under one great forest. The streams had not been obstructed by the cutting down of trees across their beds, (by which, in many cases, streams have since been choked, and swamps thereby formed, or greatly extended.) No dams had obstructed the free and regular course of the streams, and therefore no great artificial floods were formed. The soil not having been cultivated, was not exposed to be washed away by the rains into the rivers. The waters therefore were generally clear, instead of being generally muddy, as since all these circumstances have been changed. In this former state of things there could have been existing but few sources of malaria.

The first sources formed by the civilized settlers, was in making ponds to supply water-mills. But while these were yet few in number, the constructers of course chose the best and most unfailing streams; and the ponds were also, for a long time, surrounded by dense and tall forests. Such hilly land as the margins of the ponds would certainly not be brought into cultivation, while so much that was far better, and easier to till, remained unoccupied. Hence, such ponds produced but little malaria, and that little was warded off from the settlers, or taken up, by the forest growth. The general wooded state of the country, also, for a long time, rendered the supplies of water more regular, and prevented the severe droughts, which would have altered greatly, as is usual now, the levels of the ponds.

The clearing, cultivation, and consequent washing of the lands of the upper country, greatly increased the muddiness, and quantity of alluvial deposite of the rivers, and thereby increased the marshes both in breadth and in height. More mills continued to be built, and on streams worse and worse for water-power, as the choice became less open, and the mill-mania began to grow; and, in the general, each successive construction of a pond was less productive of profit, and more productive of disease, than its predecessors. The number of mills not only continued to increase, and is increasing to this day, and in the oldest settled parts of this state, as well as the newest, but gradual changes also took place in the condition of the old mills which greatly increased their fitness to produce disease. By the long continued deposite of mud from the streams, and the washing of the now cleared and tilled hill-sides, the ponds became more shallow, and the waste of water by evaporation therefore became greater; while the supply was lessened, in consequence of the extended clearings of the great forest which had before covered the whole country. To remedy the increasing deficiency of water, the owners of old mills, who were not prohibited by circumstances, raised the level of their ponds; which by increasing their surface and their contents, still more increased the daily evaporation, and also the violence of floods, and the variable height and surface of the water; all of which again combined to increase, still more than before, the product of malaria. The consideration of the progress of all these circumstances, and their bearing on each other, will serve to explain why a particular neighborhood might formerly have been healthy, though having two or three mill-ponds within or around it; and why it might gradually have become very unhealthy, in the course of time, by the malaria produced by the ponds of the same mills, or perhaps by the addition of one more new pond, to the former number. But, in such cases, so gradual would be the general change, and so irregular and variable the attacks and virulence of the autumnal diseases, that the sufferers would not attribute the change, (even if they admitted it to have taken place,) in their average degree of health, to causes which had so long existed, without being charged with doing mischief; and in which causes, no change of condition had been observed. Add to this, that self-love makes every man reluctant to believe, and to confess, that his own farm, or his own neighborhood, has become more sickly; and the change for the worse is attributed to transient causes, until the former state of things is almost forgotten, and the present is received as if it had always been the usual condition of circumstances.

During all this time, other causes were working to produce other nurseries of disease, and impediments to agricultural products and improvement. The wet alluvial bottom-lands, bordering on small rivers and still smaller streams, were for a long time neglected, and deemed of little value, except for their fine white-oak, cypress, and other noble timber trees. These were cut down so as to fall into or across the streams, when in reach, more often than otherwise; and in consequence of such obstructions, continually increased in number for more than a century, the before open streams were choked, and the bordering low-grounds converted to swamps; and those which had been swampy at first, were made still more so, by obstructing the sluggish streams and spreading them over the whole surface, and causing that surface continually to rise, by fallen trees and alluvion. But wet as are such swamps for the greater part of the year, most of the surface is dry in autumn; and the scanty water is then stagnant in numerous pools, until added to by the first heavy rain, or a flood from a mill-pond discharged above. Of course all these circumstances added enormously to the previous annual decomposition of vegetable matter, and consequent production of malaria. Such swamps as these, formed by nature and increased by art, are those on the Chickahominy, Blackwater, and many other long but gentle streams. To form or increase their evil qualities and tendencies the law has given full permission, and no small aid; but it positively, though indirectly, *forbids the drainage* of all such extensive swamps, and preserves them still as mere nurseries of disease. A general law for permitting and facilitating, under proper regulations, the draining of these great swamps, would be a measure which would be most beneficial, not only for improving the healthiness, but for increasing the agricultural products of the country.

But though the tendency of the general changes in the physical condition of the country was to increase the causes of autumnal diseases, there were numerous particular exceptions, in works serving to promote health. Of this kind were the opening and straightening of the choked channels of small rivers, and many large streams, in the hilly country, where there was enough descent to enable each individual proprietor of flooded low-ground, to relieve it by operations confined to his own land. The effectual drainage of much land of this kind has produced so much benefit to health, as, in many cases, to balance, and even exceed, the increasing pestiferous effects of the neighboring mill-ponds. Such facts would be taken, by most persons, as proofs that the increase of mill-ponds had not increased disease.

Such benefits have been produced by the gradual draining of the extensive low-ground of Gloucester, which in its former and natural swampy state, must, necessarily, have been an abundant source of malaria. This change, together with other circumstances stated in the recent description of that part of the country, has operated to render the Gloucester as free from bilious disorders as any part of the tide-water region—save the adjoining county of Matthews.* The remarkable general state of healthiness of all these very low lands, at present, as well as the exceptions, and evident causes of the exceptions, furnish the most clear and important evidence of the truth of the position, that mill-ponds, and floods of fresh-water discharged over salt-marshes, are the great sources of malaria in Virginia. As stated formerly,† there are but few fresh-water streams discharged on salt-marshes in these two counties, and not a pond-mill on the low-grounds, nor indeed in the whole county of Matthews, save one on its border nearest the high-land. The facts presented here, alone, will prove the great and certain benefit to be obtained by even a partial and imperfect avoidance of the action, separate and combined, of these two great sources of malaria.

The most important part of this subject is the consideration of the remedies for the evils described. But although the means available for this end, in my opinion, are ready, cheap, and sure, still it is needless at present to argue in their favor at great length. Unless the people are aroused to a proper sense of the evils under which the country suffers, no regard will be paid to the consideration of proper remedies; and if the former object can be gained, the latter will then necessarily follow.

The most important of these remedies, and of which the proper use, I maintain, will remove nearly all the existing sources of malaria, and make lower and middle Virginia in general as healthy as any region of the earth—will be merely here stated concisely but distinctly.

1st. To prevent the continuance of any mill-ponds of very uncertain supply, and variable "head," or height of water.

2d. To furnish to the land-floods, of streams swollen by rains, or by any mill-ponds still left, the quickest and best possible discharge to tide-water by open canals, so as to prevent the fresh-waters passing over any salt-marshes.

3d. To drain the great flat swamps; all of which require a continued canal to be extended from the lowest out-let, up to the head of the supply of water, in the most effective course, and on a general plan, through the lands of many different proprietors. The drainage of lands, so situated, is effectually forbidden by the existing laws; as there is no power to act, unless all the proprietors concur in every particular of the execution and expense of the drainage; which is obviously impossible.

4th. To refrain from embanking from the tide any marshes of the usual putrescent and perishable soil.

5th. To apply marl or lime to all lands needing calcareous manures, and on which they could be furnished at not too great cost for even such great improvement of soil and product, as would certainly be obtained in such cases.

The two last means of prevention are altogether within the province of individuals, and will be used, or not, according to the views of different individuals, as to the agricultural profit to be expected from such operations.

---

* See the facts and reasons stated more fully at p. 179 and 190, in the last number of Farmers' Register.

† The same, p 190.

The three first-named means of remedy would each require the action of the legislature, to enable them to be used to any extent.

The necessity for a general plan being authorized by law for inducing and compelling combined operations to drain swamps on long and sluggish streams, though merely for agricultural improvement and profit, is already evident to most intelligent farmers; and perhaps nothing is now wanting to procure such legislation, but the proper exertion of some of the individuals who are most interested on the subject.*

The giving free vent to land-floods, also, by wide and straight canals, and preventing them, by dikes, from overflowing the salt-marshes, though a kind of work requiring public money, as well as legal authority, still may be hoped for, when the necessity of the measure shall have been made evident.

But there is no such prospect of success as to the most important reform needed, in the putting down of all fever-breeding mill-ponds; and he who will venture to advocate this general measure, will be regarded by most of those whom he aims to serve, as more an enemy than friend to their interests, and more deserving to be treated as a lunatic, than to be respected as a judicious advocate for valuable public improvements. It is not in the vain hope of now enforcing my views by extended argument, but to offer explanations, and thereby prevent misconstruction, on some particular points, that some further remarks will now be offered.

Even if the public mind had been prepared for a full legal reformation of the police of mill-ponds, and for the laying dry all such as are nuisances to health, there would be no accompanying necessity for injuring the private interests of mill-owners, nor of causing material loss or inconvenience to the customers of the mills. In the first place, in justice to the vested rights of the millers, (however unjust to others, and injurious to the public may have been the original creation of their rights,) I would advocate full compensation being made for every sacrifice of value in their ponds, which should be required and compelled for the general benefit. But *not more* than full compensation for all value thus destroyed should be granted; and many of the fever-breeding ponds have really no pecuniary value to their owners or to the public; and most others may, to greater advantage, be supplied with water by canals, instead of by ponds. Even if one-third of all the mills should be thus put down entirely, these would be such as now always fail in dry seasons; and the more permanent and regular supplies of water, which all the remaining mills would receive from the canals substituted for ponds, would render them able to furnish the whole country with meal, with regularity, certainty, and in abundance, and therefore more suitably and conveniently to the consumers, than all the mills, good and bad, now in operation. By an important innovation in the law in regard to mills, (enacted March 2d, 1826,) every owner of a mill is authorized to cut a canal through the lands of other persons, if required by the nature of the locality, so as to substitute the pond by a canal. Before this amendment of the old law, no mill-owner could effect any such improvement, unless in the rare case of his own land extending under the whole course of the desired canal. The privileges offered by this new provision have already been availed of in many cases, in Charlotte, and the neighboring counties, and to great advantage in regard to health as well as to increased power to the mills, and great value gained in the rich drained bottoms of the ponds being put under cultivation. Slow as such lessons are usually learned, and slow as new agricultural improvements are brought into extended use, this highly beneficial and profitable improvement, cannot fail to be adopted generally in the course of time.* The main obstacle to the early and general substitution of canals for ponds, wherever the change is practicable, is the absurd legal distribution of rights in the mill-ponds and the land which they cover, as stated on a preceding page (223); one person being vested with the perpetual right to keep the land overflowed and worthless, while others have the right of property in that land, to be exercised only in the never-expected event of the owner of the pond drawing it off and draining the rich bottom; and that for the gain of others, more than himself. Now I would get rid of this absurd conflict of rights, by vesting the full property in the land covered, in every mill-owner who would draw off the pond; or if he did not avail of the privilege offered, the land should be given up to its former owners, or to any one else, who would construct a canal, and thereby secure to the use of the mill an equally good supply of water-power.

Each of the several remedies proposed and stated above, would alone furnish a fruitful subject for investigation and discussion. But more extended remark from this source, is as yet uncalled for. Other persons, having better practical information, and thereby prepared to confirm or to disprove the positions here assumed, are invited to aid in the discussion. Let the truth be made known, on whichever side it may be found; and should all facts and deductions presented serve to show that the present system greatly needs reformation, and to awaken the public to the importance of the object, then will be the suitable and propitious time to ask attention to remedies proposed for the then acknowledged evils, inflicted by the action or permission of the government. Whenever the legislature is prepared to act decisively on this whole question, there will be before them a subject for the internal improvement of of Virginia, far more important in beneficial results, than the roads and canals which have cost millions of dollars to the treasury; and yet which will be cheaper, compared to the profit to be certainly counted on, than the most humble or contemptible job yet carried through by public expenditure and as a public improvement.

But according to the existing law, any single individual who clearly sustains injury to health from any particular mill-pond, has even now the legal power to have that particular nuisance abated, by means of suit for damages for the injury thereby sustained. It has been judicially settled, that such ground of suit for damages is not prevented by any previous assessment by the first jury, nor by any lapse of time during which the mill has

* See Far. Reg. vol. I., pp. 232, 386, 518, 783, 781.

* See facts and statements on this subject at p. 231, vol. V., pp. 1 to 3.; p. 579, vol. II.; p. 374, vol. IV.

been standing; nor is the ground removed by the new damages awarded for injury already sustained and sued for. No matter how often damages may have been given to the plaintiff by successive verdicts, and paid by the defendant, there will continue ground to sue, and recover, as long as the pond remains, and is hurtful. It is surprising that the law, so favorable to the interests of mill-owners, and regardless of all conflicting interests and rights of other persons, should have permitted, in this particular, so much of remedy for the previous injustice and injury inflicted by the law. And it is still more surprising, that after legal decisions have so clearly shown the remedy, that of so many thousands of individuals who are unquestionably suffering every autumn from the neighborhood of stagnant mill-ponds, so few should have availed themselves of the offered means of relief.

If the importance of this general subject were duly appreciated, its investigation would become an object of the care, and be conducted at the expense of government. If the legislature of Virginia (for example) would institute a "General Board of Health," or "Commission of Sanitary Police," for the purpose of investigating the subject of malaria thoroughly, and of reporting the sources and proper remedies, the body of evidence which would be collected, and the after-results, might be made worth many millions of increased pecuniary value to the state, besides the far greater benefit to be produced to the health, the physical and moral qualities, and the general happiness of the people. At any possible cost of such an investigation, and of the system of measures founded thereon, the public improvement and benefit produced thereby would exceed the expenses an hundred-fold.

CHINESE TREATISE ON RAISING SILK-WORMS.

[We are indebted to the attention of the Hon. John Forsyth, Secretary of State, for a very curious work, which, upon his recommendation, and we may say under his auspices, has recently been translated and published in this country. It is an octavo volume of 169 pages, and 10 plates, published by Peter Force, Washington, February, 1838, and entitled a '*Summary of the principal Chinese Treatises upon the Culture of the Mulberry and the Rearing of Silk-worms.*' The American publisher's note states that—

"This "SUMMARY" was first translated from the Chinese, by Stanislas Julien, member of the French Institute, and professor of Chinese Literature, in the College of France, and printed at the Royal Press, in Paris, by order of the Minister of Public Works, Agriculture and Commerce. The French copy from which this translation was made, was transmitted from Paris, to the SECRETARY OF STATE, and by his recommendation has been translated and published here."

The body of the work consists of numerous extracts from various Chinese works and authors, on the culture of the mulberry, and all the different parts of the management of silk-worms, and the cocoons. The Chinese originals of these extracts, are of various ages, but generally of very ancient date, and some are as old as 4000 years. Independent of any economical value, in the furnishing instruction in unknown and useful practices, this work is a literary curiosity, which cannot fail to be interesting to every general reader who knows any thing of the remarkable peculiarities of the Chinese people. That nation had reached a very high degree of civilization, and of advancement in learning and the ornamental and useful arts, many centuries before any part of the now enlightened portion of the world had emerged from ignorance and barbarism. The Chinese were thousands of years ago but little less advanced in these respects than now; and if they have learned less (as is the case in a very remarkable degree) than any rising people, they have also lost nothing of the acquisitions in knowledge which they possessed thousands of years ago. If, therefore, from their books and their present practices we can learn nothing novel or of late improvement, in China, we may surely count on meeting with instructions and practices approved by the experience gained through many centuries, by the most industrious, careful, and economical people in the world.

But it is not merely to readers of literary or antiquarian taste that this book may be interesting and valuable. There are many particulars of management recommended which are different from any used in Europe or this country; and if, to any of these practices, the Chinese owe their great and peculiar success in rearing silk-worms, and in silk culture generally, then there may be much value gained by adopting some of their methods, novel to us, though perhaps in use twenty or thirty centuries in China. In a late number of the Farmers' Register there was republished the novel information that rice-flour was a useful addition to the food of silk-worms; and this new discovery is found among the very old instructions presented in this Chinese work.

Other and more important differences of practice are exhibited in the manner of giving food to the worms, and especially in the numerous times of feeding, through night as well as day. In regard to other things, we quote the last paragraph of the "Introduction" to the French version, by M. Camille Beauvais, who is one of the highest European authorities on silk culture.

"I should like, in terminating these reflections, to call the attention of the reader to some important points of the Chinese work; for example, upon the manner of making the butterflies lay their eggs, and of preserving the eggs; also, of the means employed to make them hatch at the same time. I will point attention, from the same authority, to the disastrous effects which result from the sudden introduction of cold and damp air in a silk-room, where the temperature is high, as well as the fatal influence which is produced by the fermentation of the leaves, upon the health of the silk-worms. I will add another fact, to give in a few words an idea of the incontestable superiority of the Chinese methods over the European: it is, that *they hardly lose one silk-worm out of a hundred*, while the Europeans *lose fifty out of a hundred.*"

We shall copy from the American version of the Chinese work the part containing instructions for managing the insects, from the egg to the end of the feeding; and also a part of the "Advertisement" of the French translator, S. Julien. In the last mentioned, our readers will probably find cause for astonishment in the account of the great number of Chinese books on agriculture.—ED. FAR. REG.]

Extract from the Advertisement of the Translator.

A stranger to the *sérigène* industry, and to the science of agriculture, it does not belong to me, above all, after the introduction of M. Camille Beauvais, to speak of the practical advantages which the Chinese work offers, and of which I now publish the translation.

I will only present to the reader some details, purely literary, of which, some will not, perhaps, be uninteresting. The Chinese, whose literature is the richest in the world, possesses many hundred works upon agriculture, which. among us, always comprises the *raising of silk-worms and the cultivation of mulberry trees.* They have also particular treatises, such as the *Tsan-chou*, the *Tsan-king* (books on silk-worms); the *Nan-fang-tsan-chou*, methods used in the south; the *Pé-fang-tsan-chou*, methods used in the north of China, the *I-sang-tsong-lun*, general considerations upon the cultivation of mulberry trees, etc. But among the twelve thousand Chinese volumes which the Royal Library possesses, there are but three works which treat in a manner more or less extensive of the double question which occupies us. The first is a small Encyclopædia of the Arts and Trades, in 3 volumes, 8vo., entitled *Thien-kong-khaï-we*, of which the second edition has appeared in 1636. Brief proceedings are found there, which competent persons have thought very interesting. I have given them the greater part in the Supplement, (page 187–169.) The second work is found in an agricultural collection of sixty books, entitled *Nong-tching-tsiouen-chou.* It has been composed by *Siu-Kouang-ki*, who, after having obtained the degree of Doctor, occupied successively the most eminent offices, and became preceptor to the eldest son of the Emperor. We see in his biography,* that in the 35th year of the reign of *Chin-tsong* (1607), he received lessons from a learned European named *Li-ma-teou*, (the celebrated missionary, Matthew Ricci), and that he studied under his direction astronomy, mathematics, in their application to the Chinese calendar, and the theory of fire-arms. The Emperor *Ssé-tsong* having heard that *Siu-kouang*, who had just died, had left a great work on agriculture, entitled *Nong-tching-tsiouen-chou*, ordered it to be presented to him by the nephew of the author, and ordered it to be printed at the expense of the state.

The third work is entitled *King-ting-cheou-chi-thong-khao*, or a General Examination of Agriculture, composed by order of the Emperor. It is twice as extensive as the preceding collection, and is composed of LXXVIII books, distributed in 24 volumes, small, in folio, printed with all the care and elegance that distinguishes the imperial editions. This compilation, undertaken a hundred years after, (in 1739,) in virtue of a special decree, by learned men of the first order, aided by the most skillful agriculturists of the empire, gives him a high importance. The extent of this work, its official character, and recent date, if compared with the two collections above-mentioned, have made me resolve to extract from it the Treatise on the *Cultivation of Mulberry Trees and the Raising of Silk Worms*, the translation of which the Minister of Commerce has intrusted to me.

If I was not afraid of being misled from my subject, I would make all the objects known which this agricultural encyclopædia embraces. I will content myself to say that a complete treatise can be found there, (books XXI--XL.) of leguminous plants, of grain, and particularly of the cultivation of rice, accompanied by a number of figures engraved with care, of which more than a hundred represent the ploughing instruments of the Chinese, and the machines which they make use of for the irrigation of the fields. The part which I have translated occupies books LXXII, LXXVI.

The reader will be able to form an idea of the immense riches of the Chinese literature, by learning that the agricultural collections, entitled *Cheou-chi-thong-kao*, from which my translation is extracted, made a part of the library of the most estimable works in China, of which the publication was ordered in 1773, by the Emperor *Khien-long*, and which, according to the decree of this prince, was composed of a hundred and sixty thousand volumes. This collection was to form four libraries, called, *Ssé-kou*, or the *four Treasures.* It yet continues to be printed, and in 1818 there had already appeared seventy-eight thousand six hundred and twenty-seven volumes, of that vast collection. There has been published by order of the Emperor two accurate catalogues; one very much abridged, in fifteen small volumes, 12mo., (Peking, 1775,) and the other very extensive in one hundred and thirty-eight volumes, 8vo., (Peking, 1782.)

—

THE RAISING OF SILK-WORMS.

PRELIMINARY OBSERVATIONS.

Testimony from Chinese authors, who speak of the cultivation of the mulberry, and the raising of silk-worms, from the most ancient times, (4438 years ago,) down to the year 976 of the Christian era.

In the Book on Silk Worms we read:

"The lawful wife of the emperor *Hoang-ti*, named *Si-ling-chi*, began the culture of silk."

It was at that time that the emperor, *Hoang-ti*, invented the art of making garments.

Observations by the Translator.—The same fact is mentioned more in detail, in the General History of China, by P. Mailla, in the year 2602, before our era, (4438 years ago.)

"This great prince, *(Hoang-ti,)* was desirous that *Si-ling-chi*, his legitimate wife, should contribute to the happiness of his people. He charged her to examine the silk-worms, and to test the practicability of using the thread. *Si-ling-chi* had a large quantity of these insects collected, which she fed herself, in a place prepared solely for that purpose, and discovered not only the means of raising them, but also the manner of

* *Ming-ssé* (Annals of the Dynasty of the *Ming*), book CCLI, folio 15, imperial edition, of twenty-four historians of the first order, in 700 volumes, small folio. Peking, 1739.

reeling the silk, and of employing it to make garments."

It is through gratitude for so great a benefit, says the history, entitled *Wai-ki*, that posterity has deified *Si-ling-chi*,, and rendered her particular honors, under the name of the *Goddess of Silk Worms.* (*Memoirs upon the Chinese.* Vol. 13, page 240.)

—

It is written in the chapter *Iu-hong*, of *Chou-king*, one of the five canonical books of China:

"The mulberry trees may be planted and the silk worms raised."

Observation.—According to the annals of China, this chapter was composed about the year 2205 before Christ, (4041 years ago.) See the *Chou-king*, translated by P. Gaubil, page 45. [St. Julien.]

—

It is written in the *Book on Worms*, one of the five canonical books, chapter *Pin-fong*, ode 1:

"In the month, when the silk worms are fed, (in the fourth month,) the leaves of the mulberry trees must be gathered."

Observation.—This chapter was composed by *Tcheou-kong*, uncle to the emperor *Tching-wang*, about the year 1115 before our era (viz.: 2951 years ago.) [St. Julien.]

—

We read in the *Li-ki*, or Book of Ceremonies, one of the five canonical Chinese books,) in the chapter *Youeï-sing*:

"In the last spring month, the young empress purifies herself, and offers a sacrifice to the Goddess of Silk Worms. She goes to the fields, situated to the east, and gathers mulberry leaves herself. She forbids the noble ladies and ministers' wives all ornamental dress, and she dispenses with the labors of her waiting-women, who sew and embroider, so that they may be able to give all their attention to the raising of silk worms."

Observation.—The *Li-ki*, (or Book of Rites,) from which this passage has been extracted, was compiled by Confucius, whose birth was 551 years before Christ.

The work we translate has many similar passages, which relate to the fourth and eleventh centuries before Christ. [St. Julien.]

—

In the work entitled *Nong-sang-thong-kioué*, we read:

"The place called *kien-kouan*, (or the house of cocoons,) is that where the empress herself raises silk worms. In ancient times, there was a plantation of mulberry trees, belonging to the state, and a building called *Tsan-chi*, (or the house of the silk worms,) which had the same destination as that which is now designated by the expression, *kien-kouan*, namely, the house of cocoons.

"The young empress purifies herself, and offers a sacrifice to the Goddess of the Silk Worms, as an example to the whole empire, and to promote the general culture of silk. The empress repairs to a mulberry plantation. She first cuts a branch; an attendant, who holds a basket, receives the leaves of the mulberry trees; afterwards, the empress cuts three branches. A maid of honor, endowed with the title of *Chang-chou*, (or President,) throws herself on her knees, and says: It is enough. The attendant who holds the basket receives the leaves, and carries them to the silk worms. It is forbidden to carry the leaves of the mulberry tree to that part of the palace called *Ken-chi*, or the golden house."

—

In the history of the emperor *Hiao-wen-ti*, whose reign began in the year 163, before Christ, it is observed:

"By a decree, the empress was commanded to gather the leaves of the mulberry trees herself, to feed the silk worms, and to furnish the garments destined for sacrifices."

—

The year 156, *before Christ.*—The emperor *King-ti*, made a decree, and commanded the empress to gather some mulberry leaves herself, in order to set the example to the whole empire.

—

The year 48, *before Christ.*—The mother of the emperor, *Youen-ti*, visited the house of cocoons, (or of the silk worms,) and followed by the empress and the ladies of the palace, she went and gathered some mulberry leaves.

—

The year 58, *anno Domini.*—Under the reign of *Ming-ti*, of the dynasty of *Han*, the empress and her attendants raised silk worms.

—

The year 220, *anno Domini.*—Under the dynasty of *Weï*, the wife of the emperor *Wenti*, raised silk worms, in a place situated to the north of the city, so as to conform to the ritual of the dynasty of *Tcheou*. [Work composed in the tenth century before Christ.]

—

Between the years 265 *and* 275 *anno Domini.*—Under the reign of *Wou-ti*, of the dynasty of *Tsin*, in the years of *Thaï-khang*, the emperor built a house called *Tsan-kong*, for the silk worms. The empress went herself, to gather mulberry leaves, in order to conform to the ancient customs of the dynasty of *Han*, and those of *Weï*.

—

Between the years 454 *and* 457, *anno Domini.*—Under the dynasty of *Song*, the emperor *Hiao-wou-ti* had a house constructed for the silk worms.

The empress gathered, herself, the leaves of the mulberry trees, conformably to the usage of the dynasty of *Tsin*.

The author of the work entitled *Nong-sang-thong-kioué*, continues to quote some analogous facts, which he had gathered from the history of the emperors, from the years of *Thien-pao*, (from 968 to 976,) of the dynasty of *Song*, under which he lived, so as to show, that from the highest antiquity, the empress raised silk worms as an example to the whole empire.

—

In the work entitled *Tsan-lun*, or Considerations upon the Silk Worm, we notice:

"Every species of tree requires a particular soil, except the mulberry tree alone, which grows every where; and, consequently, there is not a single place in the empire where silk worms cannot be raised."

The book on worms says, in chapter *Pin-fong*, (composed about the year 1115, before Christ:)

"A young girl takes her elegant basket and follows the concealed paths, to gather mulberry leaves."

By this passage it is seen that silk worms could be raised in the country of *Pin*.

Observation.—The country of *Pin* corresponds with the territory of which *Si-gan-fou* is now the capital, of the present province of *Chen-si*, which is situated in the northwest of China.—[St. Julien.]

—

In the ode of *Tsang-tchong-tseu*, of the same work, we read: "Take care not to destroy our mulberry trees."

This passage shows that silk worms could be raised in the country of *Tching*.

Observation.—The country of *Tching* corresponds with the country of *Tching-tcheou*, a dependency of the department of *Khaï-fong-fou*, in the province of *Ho-nan*, which is situated in the centre of China. [St. Julien.]

—

In the ode entitled *Tche-sin*, we read:

"The mulberry trees grow upon steep hills, and poplar trees in moist valleys."

This passage shows that silk worms could be raised in the kingdom of *Thsin*.

Observation.—The country of *Thsin* corresponds to *Thaï-youan-fou*, which is now the capital of *Chan-si*. That province is situated in the north of China. [St. Julien.]

—

In the ode entitled *Mong*, we observe:

"The mulberry leaves have not yet fallen; they are fresh and abundant." (*Ibid.*) "The mulberry leaves become yellow and fall."

Also, in the ode entitled *Sang-tchong*:

"He made an appointment to meet me among the mulberry trees."

These two passages show that silk worms could be raised in the kingdom of *Weï*.

Observation.—The country of *Weï* corresponds with the territory of *Weï-hoeï-fou*, in the province of *Ho-nan*, which is situated, as its name indicates, south of the yellow river. The *Ho-nan* is situated in the centre of China. [St. Julien.]

—

In the ode entitled *Hoang-i*, we find:

"He cuts, he lops the trees, called *yen* (wild mulberry trees,) and *tché*, (thorny trees,) the leaves of which serve to feed silk worms."

This passage shows that silk worms could be raised in the country of *Tcheou*.

Observation.—The author continues to show, by quotations from ancient works, that silk worms could be raised in the country of *Tcheou*, which corresponds with a part of the actual province of *Hou-nan*, which is situated in the centre of China; in the countries of *Lou* and *Thsi*, (in the province of *Chan-tong*,) in the north of China; in the country of *Thsou*, (ancient name of the central province of *Hou-kou-ang*, of which has been formed, under the present dynasty, the provinces of *Hou-pé* and *Hou-nan;*) in the kingdom of *Liang*, which makes a part of the actual territory of *Ho-nan*, a central province of China, and in the country of *Cho*, which corresponds with a part of the present territory of *Ssé-tchouen*, a western province of China.

The author thus terminates this article: "The five kinds of seed may be cultivated, and harvests obtained, in the coldest countries of China; further, mulberry trees may be successfully cultivated under any temperature whatever."

—

CONSTRUCTION OF THE SILK WORMS' APARTMENT.

In the Book of Rites, (written by Confucius, in the fifth century before Christ,) it is observed:

"The emperor and his vassals were obligated to keep a plantation of mulberry trees, belonging to the state, and a nursery for silk worms. It was established near a river or brook of running water; its height was about eleven cubits, and surrounded by a hedge of thorny shrubs."

Same Work.—Lots were drawn by the ladies of the three palaces, and the noble-women who were pure, and surrounded with happy omens, thus chosen; were sent to the nursery, to feed the silk worms, and occupy themselves with all the care of their raising.

—

Thsi-min-yao-chou.—The windows in the four fronts of the building must be opened, and paper pasted on them, to protect the worms from the exterior air. In the interior of the silk room, fires must be lighted at the four angles.

Same work.—In the third month, at the period called *Thsing-ming*, (the 5th of April,) the women charged with the feeding of the silk worms, are ordered to prepare their dwelling, and to stop up the holes and cracks through which the air might penetrate.

Same work.—The silk worms naturally love repose, and fear loud cries; therefore, their house should be quiet, and exempt from all noise. They love the heat, and fear the damp; their apartments should, therefore, be constructed of boards. In a quiet and retired house they will not be troubled with the cries and clamor of men. In a close house they will be sheltered from the sudden south winds. In a house constructed with plank, they will be sheltered from the exhalations and damp vapors of the earth.

—

The Book on Silk Worms.—The silk worms like an apartment with a mild temperature; on the contrary, the cocoons should be kept in cool places.

—

Wou-pen-sin-chou.—The house of the silk worms ought to be distant from all impurities, and every thing that exhales a disagreeable odor, such as stables, cow-houses, &c. Care must be taken during the night, that no light may penetrate the windows, or suddenly be shown, in the dwelling of the silk worms. Do not extinguish, in the silk room, paper matches, such as emit a great deal of smoke.

When the worms are newly hatched, they fear the dust made in sweeping. They are disturbed by crying and weeping; they do not like persons to come in their apartments, who are not perfectly clean. For example: A woman who has been brought to bed less than thirty days, or who has her menses.

(That observation is drawn from another work upon the same subject.)

Same work.—Whenever the silk worms are raised in autumn, the time of their hatching is not distant from the three periods called *San-fo*. (They fall in the middle of summer.) The heat (of the summer) yet subsists, and as it occasions a great deal of dampness in the apartments of silk worms, the necessary measures must be taken for the air to circulate freely in every part of the nursery.

—

CONSTRUCTION OF THE OVEN.

In the middle of the house, a hole must be dug, of which the size and depth must be proportioned to the dimensions of the nursery. The ordinary size of this hole ought to be four feet square. On the four sides, a square brick wall, cemented with mortar, must be raised two feet in height. Cow dung must be taken well dried and reduced to powder, and the bottom of the hole must be covered with a bed of this powder, three or four inches thick. Above, a layer of small pieces of dry wood must be spread, at least five inches in diameter, which has been cut in the last month of the year. Mulberry, acacia, elm, or any kind of hard and solid wood may be used. Upon these pieces of wood spread a second bed of dry and pulverized cow dung. In the empty places, between each piece of wood, the pulverized cow dung must be well beaten down so as not to leave the smallest space; for if an empty space be left, the fire will produce flame, which may injure the house, and besides, this fire would not last for any length of time. When the hole is completely filled, and the pulverized cow dung, that covers the pieces of wood and fills the spaces between, is well pressed down, a bed of the same matter must be spread on. Seven or eight days before the hatching of the silk worms, live coals must be put on the dry cow dung and covered over with hot ashes.

The dry cow dung takes fire, and emits for six or seven days a black and yellow smoke. One day before the hatching of the silk worms, the door must be opened to dissipate the smoke, then carefully shut. From that moment the wood and the dry cow dung are completely on fire, to the bottom of the hole.

When the silk worms are young, they like the heat and fear the smoke, consequently a bright fire must not be made; moreover, a smart fire sometimes burns with force, and sometimes suddenly goes out; it cannot constantly spread an equal and uniform heat. But when the fire we recommend is once well lighted, it does not produce any smoke, and it can be preserved for one or two months without being extinguished or diminished. A mild heat is experienced without its being perceived that there is fire in the apartment. But if small branches be burnt, they will produce a smoke that will be spread throughout. It is necessary to construct, on the edges of the hole, a small square wall of bricks, about two feet high, so that the heat may ascend and penetrate to the middle of the apartment, and spread there in an equal manner. This wall will serve to prevent those persons who move round the silk room at night, from falling unawares into the hole. The house being constructed of dry and proper materials to receive the heat, the partition walls will soon become warm. The smoke proceeding from the pulverized cow dung, suffocates all the insects which might injure the silk worms.

Cow dung diffuses a wholesome smell in the apartment of the silk worms.

Observation of the Translator.—The surface of the hole ought to be covered with square tiles, pierced with holes, to facilitate the escape of the heat.

The old paper employed to cover the windows, must be replaced by white and perfectly clean paper. For fear the heat will escape, care must be taken not to raise the window shutters, or the straw mats from the windows, or the doors, during the time the old paper is being pulled off, and new pasted on. At the top of each window, place four large window blinds, or screens, of firm texture. They must be arranged in such a manner as to roll up or unroll when wanted.—(*Ssé-nong-pi-yong.*

Nong-sang-thong-kioue.—When a nursery is wanted, for the silk worms, a house must be constructed, exposed to the south. Above all, a smooth and agreeably situated place must be chosen. The best exposure is that exactly to the south; that of the south-west is not so good, that of the east still less so.

If the house is old, it must be swept with a great deal of care, and plastered a long time before it will be wanted. If it is done a short time before the hatching of the silk worms, the partition walls will preserve a dampness which will be fatal to them. Some persons cover the house with tiles, others with thatch. Timber and wood work must be plastered within and without to prevent the danger of fire. In the nursery, pillars must be placed, furnished with cross pieces, to receive the frames. The windows must have a large opening, to admit sufficient light to distinguish the sleeping and the awaking of the silk worms. Above the shelf, small dormer windows should be opened, to increase the light of the morning and evening, when required.

Even with the ground, pipes, or air conductors, communicating with the outside, must be placed at regular distances, and arranged so that they can be opened and shut easily. They will serve to dissipate dampness, or to expel dangerous effluvia.

Same work.—When persons wish to raise silk worms, they must at first open a room, situated to the east, to feed the newly hatched silk worms. They must be taken from this room before and after their second moulting. The window turned to the west, must be shut with care, because the rays of the setting sun are particularly injurious to the silk worms. The southwest wind is very dangerous for the silk worms. A row of trees, four to five feet distant, must be planted on the outside so as to shelter them.

[The author here employs many words to indicate the place of the idols, and practices of devotion, which must be followed for the success of the nursery.]

Same work.—When persons wish to feed the newly hatched silk worms, they must as first open a room with an eastern aspect. At the four angles, concave niches must be constructed, (small stoves) arranged like the three stars of the constellation of the heart, that is to say, in triangularly, in order to distribute the heat, in a uniform manner. The author adds, that the smallness of the room allows it to be easily warmed.

—

Nong-sang-thsiouen-chou.—When the silk worms are about hatching, they require an extreme heat: at that time the air is still cold. After the third sleep (or the third moulting,) the silk worms require coolness. At that period the air is warm. Besides the wind, rain, dull, and clear weather often comes on unexpectedly; the temperature of the morning and evening, that of the day and night, undergoes great changes. If under these circumstances, the proper measures are not taken, the silk worms soon become sick. But all these changes of the atmosphere may be guarded against, if the rules we have described above be faithfully followed.

All around the nursery, (that is to say, at each window,) window blinds must be placed, which can be rolled up and unrolled at will. In the middle of the room, a fire must be lighted under ground. If the silk worms require heat, and the external air be cold, the mats that cover the windows must be let down, and the heat disseminated throughout the nursery. Then the cold from without cannot penetrate there, and a mild temperature is enjoyed throughout. But if it be rigorously cold, it will be impossible to warm the apartment, even by opening the doors of the oven; clods of dry dung must be lighted on the outside, and when they are set on fire, and produce no smoke, they must be placed at the four angles of the silk room. Soon a mild heat will be spread throughout; and as soon as the cold is diminished the rest of the burning lumps must be carried away.

When the silk worms require cooling, and the exterior air is warm, the openings of the heated pipe must be shut, and the window blinds raised up; then the interior heat moderates, and the fresh air from without penetrates the nursery. If it be sultry, it will not be sufficient to raise up all the window blinds to dissipate the heat. The paper must then be removed from the windows, the small dormer windows of the roof must be opened, and the air conductors also, which are even with the ground, and fresh water must be sprinkled outside of the windows, and about the bottom of the sash. A cool air will soon circulate in every part of the nursery.

When that sultry heat is dissipated, the paper must be again pasted on the windows, and the air pipes stopped up. In this manner the silk worms are neither incommoded with the heat nor cold, from the commencement to the end of the season. They have very little sickness among them, and the cocoons are as good as may be desired. It is by observing these proceedings that all the success of the raising of silk worms depends. But the cool air must not be suddenly replaced by warm; the fire must be increased gradually. If the cold rapidly succeeds to heat, the silk worms will become yellow and soft. When it is too warm, a cool air must not be introduced suddenly in the nursery; the windows should be opened by degrees. That precaution is necessary, for if the heat be suddenly replaced by a cool air, the silk worms will turn white and die. It is a serious danger, which should be known before hand, in order to remove the causes which give rise to it.

—

ON BATHING THE EGGS OF SILK WORMS.

The old Dictionary *Eul-ya*, says there are three kinds of insects which form cocoons: 1st, the *Siang*, or the silk worm fed on mulberry leaves; 2d, the *Tcheou-in*, those fed on leaves of the jujube, and trees called *hoa* and *louan*; 3d, the *Hang*, which is fed on leaves of the plant called *siao*.

In the *chou-king*, (one of the canonical Books of the Chinese,) it is written: "The first day of the moon, of the last Spring month, the Prince's wife washes the eggs of the silk worms in the river."

—

Abridged history of the kingdom of Ou.—In the district of *Nan-yang*, the silk worms form cocoons eight times a year.

—

Kouang-tchi.—There are several varieties of silk worms, the autumn, winter, and wild silk worms.

—

Yong-kia-ki.—In the district of *Yong-kia*, there exist eight species of the silk worm:

1st. The silk worms called *Hang-tckin-tsan*, form their cocoons in the third month, (April.)

2d. The silk worms called *Tché-tsan*, that is to say, worms which are fed with the leaves of the tree *tché*, form their cocoons at the commencement of the fourth month, (May.)

3d. The silk worms called *Hang-tsan*, form their cocoons in the fourth month, (May.)

4th. The silk worms called *Ai-tchin-tsan*, that is to say, cherished and precious silk worms, form their cocoons in the fifth month, (June.)

5th. The silk worms called *Ai tsan*, or cherished silk worms, form their cocoons towards the end of the sixth month, (July.)

6th. The silk worms called *Han-tchin-tsan*, that is to say, cold and precious silk worms, form their cocoons in the seventh month, (August.)

7th. The silk worms called *Ssé-tchou-tsan*, that is to say, silk worms from a fourth laying of eggs, form their cocoons at the beginning of the ninth month, (October.)

8th. The silk worms called *Han-tsan*, that is to say, cold silk worms, form their cocoons in the tenth month, (November.)

In the same work we read:

All the silk worms of the first kind, which mature twice a year (that is to say, those that lay eggs for a second progeny the same year,) are called *Tchin-tsan*, that is to say, precious silk worms. There are few persons that raise silk worms called precious.

The worms of the fifth class, called *Aï-tsan*, or cherished silk worms, proceed from the eggs of the worms of the third class, anciently called *Hang-tsan*.

When the silk worms (of the first class) called *Hang-tchin*, have formed their cocoons, in the third month, (April.) the moths appear, and their eggs must be collected. In the seventh and eigth month, the eggs open, and the moths are hatched. A great number of persons raise this species of silk worm. They are called *Hang-tsan*, or silk worms of the third class.

When silk worms called *Aï-tsan*, or cherished silk-worms, (of the fifth class,) are wanted, eggs of the worms of the third class, called *Hang-tchin*, must be taken, and put in an earthern vessel, the dimensions of which should be in proportion to the quantity of eggs that are required to be preserved. The opening of the vessel must be stopped up with paper, then the vessel must be placed in a basin, filled with spring water, in order that the cool air may delay the hatching of the eggs.

Thus the eggs must be left from three to seven days; at the expiration of that time they hatch, and the silk worms can be raised. They are called *Aï-tchin*, or cherished and precious silk worms; they are also named *Aï-tseu*, or beloved children. They are of the fourth class.

When they have formed their cocoons, the moths come forth and lay their eggs. Seven days after the laying of eggs, they hatch and become silk worms. A great number of persons raise worms of that kind. They are the worms of the fifth class, called *Aï-tsan*, or cherished silk worms.

Care must be taken that the water surrounding the vase be of the height of the eggs it contains; for, if the exterior water be raised above the line of the eggs, they will die, or not be hatched. If the exterior water be lower than the eggs, then they will not feel the cool air, and their hatching will not be delayed. If their hatching be not prevented, they cannot be preserved from three to seven days in the vase. If they cannot be kept from three to seven days in the vessel, when they hatch, they will fail to *accomplish their task*, that is to say: they will attempt, in vain, to spin their cocoon. When the moths have come forth, and the females have laid their eggs, they cannot hatch at the end of seven days; these eggs will not hatch until the following year; but they must be deposited under the shade of a bushy tree. Some persons put them in unbaked earthern vessels. They hatch in from three to seven days, and the worms which proceed from them succeed in forming a good cocoon.

—

Tsa-hou-hing-chou.—Thirteen varieties of silk worms are now distinguished:

1st. The silk worms which have three moultings, and only hatch once;

2d. The silk worms which have four moultings, and hatch twice; that is to say: those whose eggs produce a second crop in the same year;

3d. The silk worms with white heads;

4th. The silk worms called *Hié-chi-tsan;*

5th. The silk worms of the country of *Thsou.* (*Thsou* is the ancient name of the present province of *Hou-kouang.*)

6th. The black silk worms; among them, some hatch once, others twice. (See 2d ;)

7th. Ash colored silk worms;

8th. The silk worms hatched from an Autumn moth ;

9th. The silk worms hatched in the middle of Autumn ;

10th. The silk worms called *Lao-Thsieou-eul-tsan*, (literally, old towards Autumn ;)

11th. Silk worms of the last of Autumn, called *Lao-hiaï-eul-tsan* ;

12th. Silk worms called *Kin-eul-tsan ;*

13th. Silk worms that work in the same cocoon. Sometimes two, sometimes three silk worms, spin together in the same cocoon.

In general, the silk spun by the worms, which moult thrice, differs much from that of the worms which moult four times.

—

Hai-ning-hien-tchi.—On the night preceding the period called *tsing-ming*, (the 5th of April,) those who raise silk worms envelop the eggs in a covering of cotton, and place it under them, in their bed; they think the natural heat of the human body hastens the hatching of the silk worms.

Same work.—The twelfth day of the last moon of the year (that is to say, at the end of December, or in the month of January, when there is an intercalary moon,) all those who raise silk worms bathe the eggs in salt water, expose them to the fumigations of the melongena, and envelop them in a piece of rice ball. At the end of twenty-four days they take them out; they afterwards wash them in fresh water, and wait for the coming of Spring.

—

Sse-nong-pi-yong.—The summer silk worms are of another species; they are vulgarly called *San-tsan*, or third silk worms.

The silk worms which are raised in the Spring, lay eggs for the Summer; those that are raised in Summer, lay eggs for the Autumn; those of the Autumn, lay eggs for the Spring of the following year. None of these eggs must be neglected, for otherwise eggs will be wanted for the next raising.

Same work.—The silk worms of Autumn, are also called *Youen-tsan*, that is to say: second silk worms, or silk worms of a second rearing. But in gathering the leaves to feed them, they never fail to injure the tree. It sometimes happens, that some misfortune from heaven destroys the Spring silk worms, the raising of the Autumn silk worms cannot be dispensed with, but must be done to repair the loss. But the late crops are surer and more advantageous than those of the commencement of the year.

Siu-kouang-ki, says: "The men of the present day do not raise the Autumnal silk worms; they are contented to preserve the eggs of the Summer for the crop of the following Spring. They succeed equally well."

The same author again says: "It is a very just idea to say, the Autumn silk worms serve to repair the losses which may have been experienced in the Spring, and to supply the wants of the year. In the Autumn there are many fine days ; consequently, the raising at that time promises more certain success, than that of the Spring. But now-a-days we meet with people who say : *the Autumnal silk worms can no longer find tender leaves.* We see that they are totally ignorant of the powerful reasons which may oblige them to attempt a rearing in Autumn, from the necessity of sometimes repairing the losses which have been experienced, and of supplying the wants of the year. When the silk worms are raised in the Summer, or Autumn, care must be taken to preserve them from the gnats and flies."

Same work.—After the period called *Thsing-ming*, (after the 5th of April,) the eggs commence to change. At first they assume a uniform color, and swell up; afterwards they grow round and present a pointed side. Their centre resembles the color of willow trees, in the beginning of Spring. At last they are transformed into worms, which have the appearance of small black ants. The worms which fold themselves in a circular manner, and resemble a mountain that is seen at a distance, are those which must absolutely be preserved; but those with flat heads, which are dry, and appear as if they were burnt, as well as those of a sky-blue, and yellow, or flesh color, must not be raised.

Same work.—Some persons water the eggs with salt water. That operation is called *sien-tsan*, that is to say, *baths of the silk worms.* The eggs thus washed, produce the best silk worms.

The worms of which the eggs were not washed, are called *Ho-tsan*, that is to say, ardent silk worms, (they are those of Autumn.) They are less esteemed than the preceding.

In the work entitled *Sang-tsan-tchi-choué*, we read:

"Those who wish the eggs to hatch quickly, often unfold, and roll up one by one, the leaves of the paper where the moths have deposited their eggs. (This paper should be manufactured of cotton, or the bark of mulberry trees. According to the ideas of the Chinese, they banish from the nurseries every thing made of hemp; for example: ropes and hempen cloth. Our European paper would be very injurious to silk worms.) Those who wish to retard the hatching, unfold the leaves at distant intervals, and afterwards roll them in a tight manner, without leaving the least empty space in the centre of the roll."

—

Hoang-sing-tseng, says:—The twelfth day of the last moon, in December, or in January, if there is one intercalary month, the eggs must be soaked in salt water, and taken out the twenty-fourth day. Then the silk will be much easier to wind.

—

Another author, says:—The eighth day of the last moon, the leaves covered with eggs must be dipped in water where the ashes of the mulberry branches have been boiled, or the ashes of grass. They must be taken out at the expiration of one day. The twelfth day of the second moon, a bath must be given to the eggs, on the morning of the period called *Thsing-ming;* then they must be wrapped up in cotton paper, and deposited in the kitchen. Wait until the mulberry leaves are as large as a tea-spoon, then envelop the eggs in cotton: at night they must be covered with warm garments which have been worn during the day; in the morning they must be wrapped in blankets. When the eggs are hatched, the worms must be warmed by artificial heat; but so long as they are not out of the egg, they ought to be well taken care of, and hatched by the heat of fire.

When it is desirable to soak the leaves of paper, covered with eggs, the ashes of the mulberry tree must be used; the leaves should be moistened, and powdered with the ashes. Afterwards they must be rolled and soaked in the water where a certain quantity of salt has been dissolved. If it be apprehended that the rolls of paper will swim, they must be kept in submersion, by placing them under a china plate. The paper ought to be taken out the twenty-fourth day.

The leaves must be washed in running water, to remove the ashes, or they may be washed in a basin. Afterwards they can be newly hung up in the cool air, and the eggs hatched in the beginning of Spring. If part of the eggs do not hatch, they must be kept in darkness, and nothing more is to be feared from a useless expense of leaves.

The twelfth day of the second moon, leaves of plants called *thsaï* and *yé-thsaï*, blossoms of the leek, peach tree, and white beans, must be taken. They must be crushed in water, and afterwards the leaves must be bathed in it.

When the females lay eggs, they generally stop at the end of one night. In the contrary case, the silk worms produced by their eggs, cannot all hatch together.

Same work.—Many persons preserve the eggs of the silk worms, in bamboo boxes, when they are exposed to all the changes of the damp, tepid, hot, or burning weather. If they are subjected, suddenly, from cold to excessive heat, they are affected by it in a fatal manner. The inhabitants of the province of *Tché-kiang*, call that *Tching-pou.* That expression implies, that the silk worms contract a disease, when they are in the egg, (literally, *on the linen cloth*, or on the leaves of paper.) The worms of those eggs are yellow when hatched: the worms hatched of a yellow color, are not worth the trouble of raising. They may be compared to a child who has contracted a disease in the womb. At its birth, it is weak and feeble. It is difficult to cure it of this innate disease. In general, when one wishes to preserve the eggs of the silk worms, the leaves must be spread on bamboo boards, making it so as not to be exposed to the wind or sun. Moreover, they must be covered with a silk cloth to prevent butterflies, or insects from the cotton plant, eating them.

Much snow may be expected about the first day of the last moon, it may be in the course of the last moon. Leaves covered with eggs are spread in the midst of the snow. After one day they must be taken up, and newly spread on bamboo boards, and covered as before with a silk cloth.

When Spring comes, the precise time when the eggs are about hatching must be attentively observed; powdered cinnabar, must be taken, diluted in lukewarm water, and the eggs dipped in that water. The water should be neither too cold nor too warm; it ought to be kept at the temperature of the human body.

Same work.—Before the worms are hatched, the eggs should be weighed, and the weight written on the back of the paper to which they are attached. When the silk worms are hatched, take care not to separate them from the paper. There are many persons, who as soon as they see the worms hatch, detach them from the paper, with a small broom or quill; but these little beings, as delicate and slender as a hair, or a bit of silk, cannot support the wounds given them with the broom or quill. The mulberry leaves must be cut into extremely fine shreds, and spread in an equal manner, upon a large sheet of paper. The side of the paper, on which the worms are hatching, must be applied to that which is covered with bits of the mulberry leaves. The worms liking the smell of mulberry leaves, descend themselves on the paper, destined to receive them.

Then the paper, on which the eggs were, must be newly weighed; the quantity of hatched worms will be known, and it can be calculated how many leaves will be required to feed them. It is much better to have more leaves than are wanted for the number of silk worms to be raised. Then an abundant nourishment will be had for the silk worms, and one will not be exposed to the misfortune caused by a scarcity of leaves.

There are many persons who do not make this calculation beforehand; but when the leaves are about failing, they find themselves reduced to the most painful extremities; they pawn, or sell their effects to procure them. They have the grief of seeing their silk worms tormented by hunger; the hurdles are strewed with worms that languish and die. Thus, by their want of forecast, they uselessly sacrifice the lives of a great number of these precious insects.

—

Nong-sang-tsi-yao.—It depends on one's self to retard or hasten the changing of color, in the eggs; but care must be taken to change them in a natural manner, and not to compromit the life of a silk worm enclosed in the egg.

When the leaves of the mulberry tree are grown, at eight or ten o'clock in the morning, the sheets of paper must be taken out of the vase, unrolled and hung up. There is no rigorous rule to determine the progress of the eggs. Only the first day, their color must be changed to three-tenths, the second day to seven-tenths. Then the leaves must be rolled, they must be put in a paper tube, with the two ends well pasted, and they must be replaced in the vase. The third day, towards twelve o'clock, the rolls must be again taken out of the vase and unfolded. Their color will then be completely changed.

—

Nong-sang-pi-Kioue.—The art of raising silk worms begins with the choice of the eggs, and the preservation of the cocoons. Select in the cocoon room, the cocoons that are turned towards the light (that is to say, those from the top of the cocoon room) such as are brilliant, neat, and of a firm texture.

The moths which come out the first day, are called *miao-ngo* (viz: grass moths. The latest of all, are called *mo-ngo*, (that is to say: the last butterflies.) Neither of them ought to be kept. Only those which come out after the second day must be taken. The sheets of the paper must be spread upon the cases of a shelf, then the males and females come close together and copulate. When the evening comes, the male butterflies must be taken away, and the females must be placed on sheets of paper, leaving an equal distance between them. The eggs which are found in lumps, ought to be thrown out. When the females have laid a number of eggs, they must be left on the sheets where they are deposited and covered from three to five days. When the sheets are hung up, the eggs ought to be turned outward (read: in-ward) for fear the wind may cause them to perish.

Same work.—At the winter solstice, and the eighth day of the last moon, the eggs must not be bathed in too deep a water.

After having dipped them, they must be taken out. The fifteenth day of the moon (when it is full) several sheets must be taken, covered with eggs and rolled together. Tie them firmly with a string of mulberry bark, (or of cotton,) and suspend them before the porch or vestibule of the house, at the height of a long pole, in order that they may be exposed to the cold which is felt at the close of the year. After new-year's day the rolls must be spread out, and placed upright in an earthern vessel. At the end of ten days, when the sun is above the horizon, the leaves must be taken out of the vessel. Whenever the weather has been dull or rainy, they must be exposed to the heat of the sun, as soon as they commence to hatch.

Such is the manner of bathing and preserving the eggs of the silk-worms.

Wou-pen-sin-chou.—At the time called *thsing-ming*, (the 5th of April,) take the leaves covered with eggs, which have been deposited in an earthen vessel and transport them, sheltered, from the wind to a room where a mild heat reigns, and suspend them at half the height of the apartment.

At the time called *kou-iu*, (28th April,) expose the leaves to the air and sun, but they must be inverted or turned inside out. You must roll from left to right those that were rolled contrarily, and you must roll from right to left those that were rolled the opposite way; every day you must change and roll them in a different way from the old one. After having sufficiently rolled and unrolled them, you must put them as before in the vase.

When the time of hatching approaches, the leaves must be carried to a room where they will be sheltered from the wind and sun; the silk-worms will hatch *all at once*.

Same work.—To make the silk-worms descend, when hatched, there are many persons who strike the reverse of the leaves with a small stick of peach wood. When the worms have descended, they gather them together with a small broom or quill, put them in an envelop of paper and weigh them, then spread them upon the hurdles. Afterwards, at the different periods of their existence, they experience diseases which are frequently produced by that dangerous practice.

When the worms are hatched, a bed of chopped straw must be placed on a hurdle, where are likewise placed one or two jujube fruits, cooked in the ashes. Before the hatching of the silk-worms, the leaves covered with eggs must be weighed. After the hatching, the newly hatched worms must be spread on the chopped straw, distribute them in an equal manner, and very distant from one another.

When the worms are all hatched, the empty leaves must be weighed, and the exact quantity of worms to be raised will be known.

If the rules we have just laid down are faithfully followed, not one silk-worm out of a hundred will be lost.

We see persons at the present day, who deposit on a single mat, worms proceeding from one or two ounces of eggs; they are heaped up, and pressed against one another. The infallible result is, that they lose a great number of silk worms.

When a person has newly hatched silk worms, the proceeds of three ounces of eggs, it is necessary to spread them in an equal manner upon a large hurdle. Above all, do not raise too great a number of silk worms, for, if your means only permit you to nourish the silk worms proceeding from three ounces of eggs, and, from cupidity, you attempt to raise the worms of four ounces of eggs, you will soon feel the want of space, hurdles, laborers, and fuel. In this manner you will lose, at the same time, your silk worms, and the expenses incurred in that unprofitable attempt.

—

Nong-tching-tsiouen-chou.—In the work entitled *Ssé-nong-pi-yong*, we read:

"To make silk worms hatch, the degrees of heat and cold, proper for them, must be known, and the manner of hastening or retarding their hatching, in order that *not one may hatch before or after the others.*

"The following method must be pursued:

"When the eggs have assumed an ash color, the leaves covered with eggs must be united two by two, and extended upon a clean frame. Afterwards they must be rolled up tightly and the two ends tied with a pack-thread, (of cotton or bark of the mulberry tree,) and the rolls placed upright in a clean, cool room, where there is no smoke.

"The evening of the third day, the rolls must be taken, unfolded, and extended on the hurdles. It is a very happy circumstance if none of the worms are hatched. But if by chance there are any hatched before the others, they must be taken and thrown out. Afterwards the leaves must be taken three together, rolled in a loose manner, and deposited in the room newly warmed for the silk worms. The time of the rising of the sun must be attentively observed, then the leaves must be unrolled, and spread, one by one, upon hurdles in the middle of the yard. If there is any dew the hurdles must be placed in a cool room, or under a kind of tent. Some time after, the leaves must be transported to a room prepared for the silk worms, and they must be spread, one by one, upon hurdles placed on the ground. After a few moments the silk worms will hatch *all at once*, looking like small black ants. There will not be one that will hatch before or after the others. The hatched worms must then be weighed with the leaves of paper, to know the number of silk worms to be fed, and to calculate, in advance, the quantity of leaves which will be wanted."

Same work.—When the newly hatched worms are made to descend, they must be dealt carefully with, spread upon the hurdle in an equal manner, and a proper space left between them. Care must be taken not to wound them, or to press one against the other. As soon as the worms are all hatched, the fresh and tender leaves must be taken, and cut in very fine shreds, with a very sharp knife; then they must be spread, with a coarse sieve, upon the sheets which are to receive the silk worms, and under which a bed of chopped straw must be previously spread. The cut leaves must be spread in a uniform manner, in very light layers. Afterwards the sheets of paper must be taken, where the worms newly hatched are, and they must be applied to the mulberry leaves; the worms descend themselves on the mulberry leaves. If some worms are too long a time in descending, or if they ascend upon the back of the sheet of paper, or if they do not descend, when the leaf is turned over, they must be thrown away, with the leaf to which they remain attached. They are diseased worms, that it would be impossible to raise.

Same work.—The success in raising silk worms depends on the precaution which is taken in the beginning, and subsequently, not to expose them to any danger. If the silk worms do not revive *all at once*, from their first sleep, or moulting, it proceeds from their not having changed color, and not hatching *all at once*. If they do not change color, and do not hatch *all at once*, it is because the rules prescribed to preserve the eggs, have not been strictly followed.

Same work.—In the work entitled *Thsin-kouan-tsan-chou*, we read:

"The first day of the last moon the eggs must be collected and watered with cow's urine; afterwards they must be washed with clean water. It must be so done that the sheets of paper covered with eggs be not torn. (An author advises to strengthen them with threads of cotton or silk, basted at distances according to their length and breadth.")

FOOD FOR THE SILK WORMS.

Kouai-ki-tchi.—The greater part of the spring silk worms have four moultings, all the others have but three. The inhabitants of the country of *Youé* express the idea attached to the word *mein*, sleep (moulting) by the word *yao*, youth. Thus they say: the first, second and third youth of the silk worms.

The Book on Silk Worms.—Three brilliant colors are distinguishable in the silk worm:

When they are of a shining white, feed them moderately;

When of a dazzling blue they must be abundantly fed;

When their skin is wrinkled, it is a sign that they are hungry;

When they are of bright yellow, diminish, by degrees, their food.

Thsi-min-yao-chou.—Whenever the silk worms are fed, the window blinds must be raised up, and closed again when they have finished eating. The light excites an appetite in the silk worm, (literally: as soon as the silk worms see the light they eat.) After a plentiful meal they grow and become large.

The Book on Silk Worms.—The next day, after the hatching of the silk worms, mulberry leaves, or leaves of *tché*, dried in a well-aired place, must be given to them. When they are about the twentieth of an inch long, they will eat five times during the day and night.

The ninth day they refuse food during one day and night. This repose is called the first moulting.

Seven days after, they again moult, as the first time. When they have eaten some leaves and attained the length of the tenth of an inch, they will feed six times during the day and night.

Seven days after they moult as before.

Five days after they leave off eating. This abstinence lasts for two days, (the sixth and seventh days;) it is called *ta-mien*, or the great moulting. Then the silk worms eat but half the leaf. They will feed eight times during the day and night.

Three days thereafter they have a great appetite; then they will eat the whole leaf. They will feed ten times during the day and night. Before three days have elapsed, they begin to work at their cocoons.

When the silk worms begin to feed, after each moulting, leaves must be spread lightly over them. If the leaves are thrown in upon them, sensations will be produced destructive to their appetite.

Observation by the Translator.—The preceding extract relates to silk worms of four moultings, the raising of which lasts a longer time than that of the ordinary silk worms, that is to say: silk worms of three moultings.

Ho-pi-sse-loui.—When the silk worms lay down and remain motionless, that repose is called moulting. During the time of moulting they do not eat, either the mulberry leaves, or leaves of the tree, *tché*. At the end of one day and night, they shed their skins.

There are some silk worms which have three moultings, and others four.

—

Hoang-sing-tseng, says:—From the hatching of the silk worms to their third moulting, cut leaves ought to be constantly given them. When the ardent silk worms are fed, that is to say, Autumn silk worms, they must be carefully watched. As soon as they have eaten their leaves, give them more, for they will fall sick, if they breathe the heat of the silk room fasting.

—

Nong-sang-tsi-yao.—Towards the end of Autumn, before the mulberry leaves turn yellow, a large quantity must be gathered. They must be dried and broken up in such a manner so as to be reduced almost to powder. They must be preserved in a place warmed by a fire that produces no smoke. They will answer the next year to feed the spring silk worms, after each of their moultings.

Same work.—The eighth day of the last month, (January,) small green peas, called *lo-teou*, (dolichos,) must be soaked in fresh water. They must be spread on frames, not very thick, and dried in the sun. Wash some clean rice in pure water and dry it also. These green peas and rice must be preserved in a shaded place. Flour made from them, will serve to feed the silk worms after their last moulting. It must be spread equally on the leaves given to them for food.

Same Work.—Manner of feeding the newly-hatched silk worms.—The leaves of the mulberry must be frequently cut in very fine shreds, and lightly spread over them with a sieve. The food ought to be distributed without interruption. In the space of one hour, (two of our hours) four meals must be given them, which makes forty-eight repasts in the space of one day and night.

Same work.—Food must be given to the silk worms without fail during the day and night. If their repasts are multiplied, it will necessarily result, that they will soon arrive at maturity; but if their meals are rare, and not numerous, they will attain their growth slowly.

When the silk worms attain maturity in twenty-five days, one frame or hurdle will furnish twenty-five ounces of silk. If in twenty-eight days, only twenty ounces can be obtained. If the time be one month, or forty days, one hurdle will furnish but ten ounces of silk.

Those persons who feed silk worms ought to endeavor not to sleep. Laziness has serious inconveniences.

Every time the silk worms are fed, all the hurdles must be visited with the greatest attention. It is essential for the leaves to be distributed in an equal manner. If the weather be dark and rainy, if the exterior air be cold, before feeding the silk worms, dry branches of mulberry trees must be taken, or rather a handful of rice straw, stripped of all its leaves, fire must be put to it, and the flame put around and above the hurdles in order to dissipate the cold and damp which benumbs the silk worms. After that operation they must be fed. In that manner they do not contract any disease. The time of their general moulting must be observed, and then the feeding must be suspended. Afterwards nothing is given them to eat, until they are all recovered from their torpid state. If food is given them, when they are but eight or nine-tenths of them recovered, they will not arrive, *all together*, at maturity; besides, great numbers of them will be lost.

From the second to the great moulting, (the third moulting,) when the worms assume a glossy yellow color, and when they are disposed to moult, the nourishment must be suspended, and they be transported to other frames. Afterwards, when they are all recovered, they must be slowly fed, that is to say: they must have their repasts given them at long intervals, and leaves must be spread on them in very light layers. If the leaves were distributed too abundantly, they would eat without appetite and become sick. Now, as it is the food which gives strength and life to the silk worms, the greatest attention must be paid to see that it be suitable and possesses all the proper qualities. The silk worms like not leaves saturated with rain or dew; if they eat of them, the greatest number immediately fall sick.

Same work.—When the silk worms recover from their great moulting, (their third moulting,) the heat of the rooms must be diminished when it incommodes them. At that time frequent meals must be given them. If a south wind blow, the window blinds must be let down, and the straw mats of the doors closed. At that moment they must be transported to other hurdles. When the silk worms are spread on the hurdles, the distance of one finger must be left between each one. Then the small green peas, which were reserved from the month of January, must be taken, and soaked in a small quantity of water, until they germinate: afterwards they must be dried in the sun, and reduced to powder.

The clean rice, which was also laid by in the month of January, can be employed for the same use, after having been boiled by steam, and reduced to flour. At the fourth feeding, that flour must be spread in a uniform manner, upon mulberry leaves. It will refresh the silk worms, and dissipate the internal heat they feel at that period of their age, and which is a mortal poison to them. The silk they afterwards produce, is more abundant, easier to reel, and, besides, it is stronger and more brilliant.

If there be but a small quantity of fresh leaves, the leaves which were cropped the preceding autumn must be taken, pounded again and reduced to powder. The new leaves must be lightly moistened, and the powdered leaves spread on in a uniform manner. Thus a want of leaves may be supplied. The leaves of the plant called *ou-kiu*, *(cicorium intubus?)* can also be used as a substitute for that flour.

—

Nong-sse-pi-yong.—Same subject.—Early in the morning, the roots of the mulberry trees must be watered, and the leaves gathered soon after. If they are watered early in the morning, the leaves will be very juicy; if they are gathered soon after having been watered, they will not wither.

They must be cut in fine shreds with a well sharpened knife, and spread in light layers, with a coarse sieve. If a very sharp knife be not used, the leaves will lose their juice; if they be not cut very thin, they will cover and overload the silk worms. If a sieve be not made use of, they will not be distributed in an equal manner; if the cut leaves be not distributed in an equal manner, the silk worms will not all eat an equal quantity.

The juice of the leaves is not very abundant; at the expiration of some time, it dries up; for that reason the leaves immediately after the watering require to be sifted on the silk worms.

The first day, two repasts an hour must be given them, that is to say, about forty-eight repasts in the space of a day and night.

The second day, thirty repasts must be given them, in the same interval of time, and the leaves which are distributed to them, must be cut a little smaller.

The third day, only twenty meals must be given them (during the day and night,) composed of leaves thinner than the second day. They must be kept in great obscurity and heat. Generally, the newly hatched worms require darkness. When they recover from their sleep, or moulting, a little light ought to be allowed them; at a later period, when they show a smart appetite, a great deal of light must be given them.

Same work.—Another method.—As soon as the leaves are cut very fine, they must be spread in light layers with a sieve. Four repasts must be given by the hour, (two of our hours,) which makes about forty-eight repasts in the space of one day and one night. Some persons give but thirty-six in the same interval of time. This is my opinion. The newly hatched worms only feed on the juice of the leaves. If their repasts are not multiplied, they will resemble young foster children who are deprived of milk from their infancy; consequently, they never fail to be weak, pitiful and sickly.

Leaves full of juice, which have been gathered the preceding night, from the branches exposed to the south-east, must be given them. These leaves must be kept apart, in an earthen jar, and cut up very fine as soon as they have been taken out.

Same work.—Method for diminishing the food and hastening the moulting.—When the silk worms are disposed to sleep, (to moult,) their food must be diminished in proportion to the degree of yellow or white which their skin assumes; the leaves destined for their food must be cut in fine shreds, and frequently spread in light layers.

When the silk worms are completely yellow, they ought to be transported, in succession, to other hurdles, without caring whether the sky be dark or serene, if it be in the morning or the middle of the night. When they have been transported to other hurdles, the feeding must be suspended until they have all recovered from their moulting, when they may be fed again. This is called *diminishing the food* and *deciding the moulting*. These two expressions imply, that the nourishing of the silk worms, which are disposed to moult, must be diminished, (care must be taken not to cover or overload them with leaves,) and, on the other side, the silk worms must be abundantly fed, (which are not disposed to moult,) in order that they may quickly moult. Not only will they *all moult together*, but they will be exempt from diseases caused by the accumulation of leaves, and the internal heat which consequently follows.

—

Nong-sang-thong-kioue.—The silk worms may be found in ten different situations: They may be cold or hot, starved or satiated, sufficiently far apart, or too near together, asleep or awake; they may eat slowly or with appetite.

Same work.—Injurious things to the silk worms.—1st. The silk worms do not like to eat damp leaves;

2d. They do not like to eat warm leaves;

3d. The newly hatched worms do not like the smell of fish, fried in a pan;

4th. They do not like to be in the neighborhood of persons who pound rice in mortars;

5th. They do not like to hear strokes on sonorous bodies;

6th. A woman, who has borne a child within a month, ought not to be *the matron of silk worms;* that is to say: ought not to be charged with the raising of silk worms;

7th. They dislike men, who smell of wine, to give them food, to transport them from one place to another, or to spread them on hurdles;

8th. From the time they are hatched, until maturity, the silk worms dread smoke and odorous exhalations;

9th. They do not like to have skin or hair burnt near them;

10th. They do not like the smell of fish, musk, or the odor of certain herbaceous animals, (like the goat, &c.;)

11th. They do not like to have a window, exposed to the wind, to be opened during the day;

12th. They do not like to receive the rays of the setting sun;

13th. They do not like, when the temperature of their habitation is warm, to have a sudden cold or violent wind introduced there;

14th. When their habitation is cool, they do not like a sudden change to excessive heat;

15th. They do not like dirty and slovenly persons to enter their room;

16th. Care must be taken to keep all noxious effluvia and filth distant from the apartments of the silk worms.

Same work.—The third day between ten and two o'clock in the afternoon, three hurdles, or frames, must be placed upon another stage. The one above protects the worms from the dust; that below protects them from dampness; and the middle one is destined to receive the silk worms. Young silk worms when incommoded by internal heat must be changed. A small quantity of worms, occupying a space as large as a square of a chequer-board, must be deposited on the middle frame; they will soon cover it entirely. By degrees the quantity of food must be increased. In the morning, if the weather be clear, the window situated to the east can be opened, and during the day, those which are in an opposite direction to the wind. By degrees they will change color; and, according to the color they assume, their food must be increased or diminished. When they are completely yellow, food must not be given them. They remain motionless, and that is called *theou-mien*, (or the first moulting.) When they have been removed after their first moulting, six meals may be given them, during the space of one day and night. The second day the quantity of leaves must be gradually increased. The windows can be half opened. From the first moment they begin to turn yellow, they must be kept very warm. When they are entirely torpid they require a great deal of heat; when they are perfectly recovered, they only want a moderate heat.

When the silk worms are removed, after their second moulting, and are all recovered, light repasts ought to be given them at first. Four repasts in one day and night will be enough. The next day the quantity of leaves may be augmented by degrees. Some persons open the windows.

From the first moment they begin to turn yellow, they require a good heat; when they are once torpid, a moderate heat ought to be allowed them; when they are all recovered they require a mild heat.

When the silk worms are removed after their third moulting, and they are all revived, three repasts must be given them during one day and night. The first repast ought to be very light; the second lighter than the first, the third the same as the first. If these three repasts be not administered with much caution, the silk worms will feed slowly until the period of their maturity. The second day, the quantity of leaves must be increased by degrees. The windows can be thrown entirely open, and the dormer windows above the frames may be likewise opened.

From the first moment they begin to turn yellow, they require a mild heat; when they are completely torpid a lukewarm heat is required; when they are all revived they require coolness. After each repast a basket of leaves must be taken, and the tour of the shelves made. If an empty place is perceived (upon a hurdle) it must be covered with leaves strewn with rice flour. After the seventh or eighth feeding, (from ten to two o'clock,) cut leaves must be spread upon the hurdles; they must be moistened equally with fresh water; then, after a lapse of some time, sifted rice flour must be spread, being careful to distribute it in a uniform manner. For each basket of leaves a *ching*, (a kind of measure,) of fresh water and four ounces of flour must be used. If the flour cannot be had, a basket of new leaves only must be used; it will furnish a repast for the silk worms of a frame.

[Extract from *Nong-tching-tsiouen-chou*. The powder of leaves, which are spread on fresh leaves, fills the body of the silk worms, (that is to say: is very nourishing,) and disposes them to make a firm and thick cocoon, the silk of which is remarkably strong.]

When the leaves are cut up, moisten them with fresh water: then sift the powdered leaves, and spread them in a uniform manner.

After the great moulting of the silk worms (the third moulting,) from three to five meals of that kind must be given them at certain intervals. When the silk worms approach their maturity, they require light and frequent repasts and moderate heat.

Same work.—If among the silk worms there be any that are backward, that is to say, which do not appear disposed to moult at the same time with the others, frequent supplies of food ought to be given them, in order to accelerate and cause their moulting, at the same time with the rest of the hurdle. When the silk worms do not moult all at once, it proceeds from a species of disease, which dates from their hatching. This method must be followed to remedy it: If among the silk worms which are completely yellow, some change their white color, and begin to turn yellow, much time is not required to become completely so. By the aid of very frequent feeding they will soon overtake the others; in fact, multiplying the feeding hastens the period of their moulting.

But when the greatest number are completely yellow, many blue and white ones are found, they are far from becoming entirely yellow, and frequent repasts given them will be useless trouble; it is impossible for the latter to arrive at the moulting at the same time with the first.

The change of color in the silk worms is the least change that is experienced. When they moult they cease eating, and shed their skin; then they experience a great change. But the greatest of these changes, is their metamorphosis from the chrysalis into butterflies, or moths. When a silk worm is completely yellow, its mouth is shut, it no longer eats but sleeps, or is torpid: it then resembles a man afflicted with some dreadful disease; the blood spreads throughout, its body experiences great modifications. If it remains a day and night without eating, its moulting produces a happy relief.

If, then, there be many blue and white silk worms, and their feeding be too much hurried, their health will be disordered, and a precocious moulting will not produce relief. When those which were blue or white turn yellow, and are disposed to moult, all the others have accomplished their moulting, and are recovered.

When the silk worms begin to recover from their moulting, they want but little food; they resemble a convalescent patient, to whom only slight nourishment is given to repair, gradually, their strength. If while the backward ones moult, the nourishment of the earliest be suspended, they will languish with hunger and weakness, yet you are compelled to wait; and besides, one will be obliged to give them food when the backward ones are recovering. A great number will contract diseases, and very little silk will be gathered from them. For that reason the author of *Tsan-king*, or the *Book on Silk Worms*, says, with much reason, that "the irregular moulting of the silk worms always causes a diminution of silk."

Same work.—When the silk worms are just hatched their color is black. Their food must be gradually increased. Three days thereafter they gradually become white; then they gain appetite. Leaves, not cut so small, must be given them. When they are blue, it is the period of their great appetite. Leaves must then be given them more abundantly, and not cut so small. When they again become white, they feed slowly; their food must be diminished a little. When they are turning yellow they have but a delicate appetite; their food must be again diminished. When they are completely yellow, they entirely cease eating; that is called their moulting. When they are recovered, they change from yellow to white, from white to blue, from blue to a second white color; at last from white to yellow; this is their second moulting. At each moulting they experience the same changes of color. They must be observed with care, in order to diminish or to increase their food, of which the quantity ought to vary, according to the different situations in which they are found.

The leaves which are given them, ought to be neither wet with dew, nor dried in the wind or sun, nor impregnated with disagreeable smells, for as soon as they have fed upon them, they will contract diseases. If care be taken to preserve, in advance, a sufficiency of leaves for three days, there will be nothing to fear from long rains: the silk worms will never have to eat damp leaves, and at the same time, they will not suffer from hunger. When leaves are again gathered, the heat arising from the accumulation in sacks, must be completely dissipated before giving them to the silk worms. The space of one day and night is, for the silk worms, like unto a year with its four seasons. The morning and evening are the Spring and Autumn; the middle of the day resembles the Summer; and the middle of the night Winter. In these four periods of the day the weather is never the same. When a good fire is preserved in the silk-room, great attention ought to be paid to keep it at the corresponding temperature for each one of those four periods. The degree of heat ought not to be constantly the same. From the time they are hatched, until their second sleep, (moulting,) the silk worms require a moderate heat. The matron of the silk worms, (the person who takes care of them, ought to wear a single garment, (that is to say not double.) She must regulate the temperature of the silk-room, according to the sensation of cold and heat she feels.

If she feels cold, she necessarily will judge that the silk worms are cold, and the fire must then be increased; if she feels warm, she will conclude from it, that the silk worms are too warm, and the fire must then be suitably diminished.

When the silk worms are all asleep, if the sky be clear and brilliant, between ten and two o'clock the windows must be opened, to introduce air and light in the apartment. If the wind be southerly, the windows to the north must be opened; if northerly, the windows on the south side must be opened. The air which enters from a side opposite to the direction of the wind cannot injure the silk worms.

When the silk worms have recovered from their great moulting, (the third moulting,) three repasts must be given them, then the paper that covers the windows, must be cut with a pair of scissors, to allow the air and light to penetrate into the apartment. The silk worms will not be disturbed or incommoded.

After the great moulting, when the windows have been opened, and the paper cut from the windows, if the exterior air is too warm, an unglazed earthen vessel must be placed at the entrance of the door, in which the water must be often renewed, in order that the air may be refreshed in its passage. If the wind raises, if it should rain, or if the night becomes cold, the windows must be closed immediately.

Nong-tching-tsiouen-chou.—The silk worms are of a warm constitution. It is better to make use of a fire during the whole time of the raising.

The following is a method of warming the nursery:

A long stove, placed upon a hand-barrow, must be made use of, so that it may be carried by two men. When the leaves are spread on the silk worms, wait until they have climbed upon the leaves, and then bring in the stove, which must be carefully lighted outside of the apartment. The fire should consist of hot coals; it must be covered over with a bed of straw ashes, to prevent a red and brilliant flame. When the silk worms have finished eating, the stove must be carried back. Afterwards, when other food is given to the silk worms, the same stove must be brought in each time. Then the silk worms will escape the diseases which heat causes; but if the stove be introduced when the silk worms are hungry, they soon become warm. If the stove be introduced soon after having given them food, that is to say, when they are under the leaves, not having had time to ascend them, they will soon be incommoded by the fermentation of their dung, and they will, besides, be overloaded by the leaves spread upon them.

Same work.—When the air of the silk-room is warm, if it be suddenly made cold, the silk worms will lose their appetite, and feed no longer. Then a chafing-dish, filled with clods of dry cow dung, well ignited, and free from smoke, and by the aid of an iron fork, must be moved about repeatedly above the frames. That operation dissipates the cold, which benumbs the silk worms, and they soon feed with an appetite.

—

ON THE DISTRIBUTION OF THE SILK WORMS UPON THE FRAMES, AND THE SPACE TO BE ALLOWED THEM.

Thsi-ming-yao-chou.—When the silk worms are moulting, three frames are constantly required. The middle frame is destined to receive the silk worms, the superior and the inferior ought to remain empty. The lower frame preserves the worms from the dampness of the ground, the upper preserves them from the dust of the apartment.

—

Wou-pen-sin-chou.—When the silk worms are about hatching, they require cool air. A bed of chopped straw must be spread on the frame; wheat straw must not be used. Every day they must be removed once upon other frames; if they are not changed, it generally happens that white spots come over them.

—

ON REMOVING THE SILK WORM.

In removing the silk worms many persons must be employed in order to perform it quickly. If they are left for a long time, heaped up in the baskets, they become heated and perspire abundantly. In consequence, a great number of them fall sick and die. By degrees they will diminish every time they are removed; and those which later arrive at maturity, will only produce small and ill-supplied cocoons.

The dung of the silk worms must be frequently removed. If it be not carried away, they become heated. The heat produces fermentation, and causes a putrid effluvia. Afterwards a large number of silk worms turn white and die.

Whenever the silk worms are removed they must be distributed upon the frames in such a manner as to leave some space between them;

if they are placed too near together, the strongest will feed at the expense of the weakest. It is necessary to make the tour of the frames often, and to visit them with care. Moreover, if the air does not circulate freely in the apartment, and the door be suddenly opened, a fatal wind may penetrate, and a great number, consequently turn red and die. When the silk worms are distributed upon the frames, it ought to be done in a tender manner; they must not be thrown down, or they will be wounded by striking against each other. The health of a great number of silk worms will suffer, and afterwards they will become what are called *laï-lao-ong;* that is to say, *lazy old men.* They leave a red chrysalis.

Nong-sang-yao-tchi.—Two frames must be placed below the one where the newly-hatched silk worms are. When the sun has risen above the horizon, a frame must be taken away and dried until the setting of the sun. It must then be replaced under the frame where the silk worms are. The next day remove a frame again from beneath, expose it to the rays of the sun and then replace it, as at first. In that manner the silk worms will naturally receive a mild and temperate heat. That frame must be removed as soon as they have eaten, after the second moulting.

Same work.—There are some silk worms which turn white and die; it arises from their having been injured by damp exhalations, within a short time after their hatching. When the sky is clear and serene, take three or four frames and carry them quickly into the apartment of the silk worms, after having exposed them for some time to the rays of the sun. Then as one frame is removed and replaced by another, so continue to change them, until all the frames of the silk worms are sufficiently warmed by the heat of the sun.

The country people, vulgarly say: "when the dung of the silk worms is dry and scattered, it is a sign that they are in good health." When the dung appears in damp heaps, and of a shining white, it announces that the silk worms are sick; the frames must then be quickly changed. But if at the time, when it is proper to change them, a damp rain or a cold wind comes on, it will not do to remove them; the straw of rushes, chopped to the size of a bean, must be taken, and one or two bushels distributed on each frame; it must be spread in an equal manner upon the silk worms. Then a layer of fresh leaves must be placed over them. Soon after the silk worms ascend to eat the mulberry leaves. The bed of rush straw separates the silk worms from the dung, and relieves them from that inconvenience. As soon as the sky has become serene, they must be removed to other frames; if a person has no rush straw, the rice straw will supply its place.

Sse-nong-pi-yong.—The silk worms produced by three ounces of eggs, which occupy a single frame at the moment of their hatching, will cover thirty frames at the close, or last period of their lives. In general, one tenth of an ounce of silk worms, newly hatched, will furnish a frame of silk worms, in supposing that the frame is as usual, ten feet long, and two wide. If the frames are of a smaller dimension, they ought to receive a smaller quantity of newly hatched worms. If they are too numerous for the space they occupy, they will find themselves close, and, consequently, serious accidents will result from it.

Those persons who intend raising silk worms, to cover more than thirty frames, ought to increase the number of frames destined for the young silk worms, (hatching silk worms.)

Those who only raise a small quantity of worms, can make use of baskets with small borders.

Same work.—The third day, between ten and twelve o'clock, three frames must be placed upon a separate stage. The hatching worms, which have deposited a light bed of dung, must be changed. It must be done with a delicate hand. A quantity of silk worms which (at the moment of their hatching,) occupied a space the size of a square of a chequer-board, ought to be distributed upon the middle frame.

REMOVAL OF THE SILK WORMS AFTER THEIR FIRST MOULTING.

Sse-nong-pi-yong.—Place four frames upon a separate stage, and the worms which have deposited a light bed of dung must be changed. When they have eaten abundantly, a quantity of silk worms, which, at their hatching, occupied a space as large a man at draughts, will fill the two middle frames; a quantity of silk worms, which occupy a space no larger than a small piece of money, will cover the third frame.

REMOVAL OF THE SILK WORMS AFTER THEIR SECOND MOULTING.

A quantity of silk worms, which at the moment of their hatching occupy a space no larger than a small piece of money, will cover six frames. When they have eaten abundantly, the same silk worms will cover twelve frames.

REMOVAL OF THE SILK WORMS AFTER THEIR THIRD MOULTING.

A quantity of silk worms, which at the moment of their hatching, occupy a space as large as two pieces of money, will cover twenty-five frames. When they are all torpid, the bed of chopped straw must be removed; they will then fill thirty frames.

To remove and separate the silk worms, in a proper manner, it must be done with promptitude and tenderness. They must be separated from one another, and an equal space left between them, for fear they should wet themselves, and reciprocally injure one another. The silk worms evacuate freely; for that reason they must, absolutely, be separated. When they have deposited a large quantity of dung, it is necessary to remove them to other frames. If they are not separated they will be too much crowded. If the frames are not changed, they will be injured by the abundant humors which they void. For that reason, these two operations ought to be performed with great celerity.

The silk worms are weak and delicate beings; they suffer much from being rudely handled. When they are small, they must be treated with great care and a kind of affection; but when they have become large, there are few who pay any attention in removing them. They are heaped together, pell mell, for a long time, and they are tumbled about, or let fall. This defect of care and precaution causes their diseases, and often destroys them; therefore, they should be touched with a light hand, and distributed upon the frames at an equal distance from one another.

Sang-tsan-tchi-choue.—The silk worms of four moultings are of a different species; they are raised in the same manner as the Spring silk worms, (which have but three moultings.) Only after the third, they must be distributed upon fifteen frames. When they have fed abundantly, they must be spread upon twenty frames; and after the great moulting, (the fourth moulting) they must be distributed upon thirty frames.

Nong-sang-thong-kioue.—Upon each stage three frames are placed; the first is destined to receive the dust of the apartment, and that below, to intercept the dampness of the ground. A bed of chopped rice straw must be spread upon the middle frame, in order that it may receive the silk worms which are removed. This rice straw must be broken, and softened in an equal manner, upon the middle frame; then a sheet of paper must be spread above, of which the extremities are pasted to the edge of the frame. Upon that sheet of paper the silk worms must be placed.

Nong-tching-tsiouen-chou.—Hoang-sing-tseng says: When it is desirable to remove the silk worms, rice straw, crushed in a mill, must be spread, in advance, upon other frames. It renders them healthy and active, and preserves them from diseases. Some persons change them by the aid of a net, which they strew with mulberry leaves.

ENTRANCE OF THE SILK WORMS IN THE COCOON ROOM.

Nong-chou.—The floor of the cocoon room must be boarded with planks of the fir tree, six feet long, and three feet wide. A frame pierced with large holes, must be constructed of the thin bamboo from which arrows are made. In these holes some reeds must be inserted; then long and large bamboo branches, stripped of their leaves must be crossed above. The cocoon room must be covered with a frame work of woven reeds.

The silk worms will then have a place, where they can establish themselves in safety without fear of falling. When the interior of the cocoon room is well arranged, when it affords the necessary depth and proper security, and the frame presents no interval, the silk worms must be successively spread over it. At first, the frame must be a little inclined, until the worms are emptied of excremental matter, afterwards they must be moderately warmed with a small brasier, or pan of live coals. When they have begun to enclose themselves in their cocoon, (that is to say, when their cocoon will have formed a light net work,) the heat must be increased by degrees. They must not stop in the middle of their work; if the temperature be a little too cold, they walk upon their silk and cease to spin. When it comes to be reeled it will frequently break. In general, one will be obliged to have the cocoons boiled, and silk stuff made of it, because it is impossible to reel it from one end to the other.

Thsi-min-yao-chou.—When the silk worms have arrived at the age of maturity, if it happens to rain, it will injure the cocoons; it will be better also to establish the cocoon rooms in the interior of the nursery.

Observation.—The round and oblong cocoons' rooms must be placed outside.

A parcel of small dry branches must be laid upon the frames, and the silk worms spread on them. When that operation is performed, they must be again covered over with a bed of dry branches. One stage, or story, can support ten large frames.

Another method.—In place of small dry branches, the stalks of plants may be used, on which the silk worms must be spread. The frames must be suspended, between wooden pillars, with cords, or hooked sticks. Several may be arranged one above another. When the frames are suspended, they must be moderately warmed by means of chafing-dishes placed below. As soon as the silk worms feel the heat, they work industriously; but if they are affected by the cold they will work slowly. The frames must often be visited. As soon as they are warm enough, the chafing-dishes must be removed. If a cool air circulates above in the cocoon room, (while the lower part is warm,) the silk will not be spoiled by the dampness produced by the silk worms; the silk worms that die, will immediately fall, and the cocoons of the other worms will not be injured by coming in contact with them, the dung will not adhere to the cocoons, nor produce any blemish. If the silk be impregnated with dampness, it will be difficult to prepare it for the die; if the cocoon be soiled, the silk will easily break; if the cocoon be defective, it will be good for nothing.

The cocoon rooms furnished with stalks of dry plants, are as advantageous as those we have just described.

Same work.—There are some countries where the place for cocoons is outside, (in the open air;) but if in the evening the air becomes cold, no silk worm can form its cocoon. When the cocoon rooms are warmed, the silk will be fitter to receive the die; besides it acquires lustre and whiteness.

Wou-pen-sin-chou.—The ground on which the cocoon rooms are established, ought to be high and level. It must be well aired in the interior. Small branches, or dry stalks of plants, must be spread there in an equal manner; afterwards, the silk worms must be distributed there, leaving a proper distance between them; if they are too near, they will create too much heat; if they are crowded, they spin with difficulty; and, moreover, their silk will be difficult to reel. The cocoon rooms must not be established in places exposed to the north-east, nor where domestic animals are raised; neither under trees, above a hole, nor near places covered with manure or stagnant waters.

Nong-sse-pi-yong.—The following is the manner of establishing the cocoon room: A dry and warm place must be chosen, in order that neither the cold nor dampness can penetrate into the interior of the cocoon room. When the worms approach their maturity, a fire must be lighted upon the ground where the cocoon room is to be located, until it is perfectly dry; afterwards, the remains of the fire and the ashes must be swept away, and the cocoon room constructed.

Same Work.—Six diseases of silk worms are noted in the cocoon room:

1st. When the silk worms dirty the cocoon room;

2d. When the silk worms fall in the cocoon room;

3d. When they move about without spinning;

4th. When they change in red chrysalis;

5th. When they turn white and die;

6th. When they turn black.

The foulness of the cocoon room arises from portions of leaves which the mature worms have brought with them; they ferment and produce a fatal moisture.

The five other diseases always result from the moisture of the ground, or the cold of the exterior air.

From the Wesleyan Methodist Magazine.

OBSERVATIONS ON PROGNOSTICATIONS OF THE WEATHER [IN ENGLAND.]

By the Rev. Adam Clarke, LL. D., F. A. S.

From my earliest childhood I was bred up on a little farm, which I was taught to care for, and cultivate ever since I was able to spring the rattle, use the whip, manage the sickle, or handle the spade; and as I found that much of our success depended on a proper knowledge and management of the weather, I was led to study it ever since I was eight years of age. I believe *meteorology* is a *natural science*, and one of the first that is studied; and that every child in the country makes, untaught, some progress in it: at least so it was with me. I had actually learned, by silent observation, to form good conjectures concerning the coming weather, and, on this head, to teach wisdom among those who were perfect, especially among such as had not been obliged like me to watch earnestly, that what was so necessary to the *family support*, should not be spoiled by the weather before it was housed. Many a time, even in tender youth, have I watched the heavens with anxiety, examined the different appearances of the morning and evening sun, the phases of the moon, the scintillation of the stars, the course and color of the clouds, the flight of the crow and the swallow, the gambols of the colt, the fluttering of the ducks, and the loud screams of the seamew—not forgetting even the hue and croaking of the frog. From the little knowledge I had derived from close observation, I often ventured to direct our agricultural operations in reference to the coming days, and was seldom much mistaken in my reckoning. When I thought I had a pretty good stock of knowledge and experience in this way, I ventured to give counsel to my neighbors. For my kindness, or perhaps officiousness on this head, I met one day with a mortifying rebuff. I was about ten years of age; it was harvest time, and 'what sort of a day to-morrow would be,' was the subject of conversation. To a very intelligent gentleman who was present, I stated in opposition to his own opinion, 'Mr. P. to-morrow will be a *foul day*.'—To which he answered 'Adam, how can you tell?' I answered, without giving the *rule* on which my prognostication was founded, 'O sir, I know it will be so.' 'You know! how should you know?' 'Why, sir,' I pleasantly replied, 'because I am *weatherwise*.' 'Yes,' said he, 'or *otherwise*.' The next day, however, proved that my augury was well drawn.

About twenty years ago, a Table, purporting to be the work of the late Dr. Herschel, was variously published, professing to form prognostics of the weather, by the times of the change, full and quarters of the moon. I have carefully consulted this Table for several years, and was amazed at its general accuracy:—for though long, as you have seen, engaged in the study of the weather, I never thought that any rules could be devised liable to so few exceptions. I have made a little alteration in the arrangements, illustrated it with further observations, and have sent it that you may insert it in the Magazine, as it has hitherto been confined generally to a few almanacs.

A TABLE *for foretelling the weather through all the lunations of each year for ever.*

This Table and the accompanying remarks, are the result of many years' actual observation; the whole being constructed on a due consideration of the attraction of the sun and moon in their several positions respecting the earth; and will, by simple inspection, show the observer what kind of weather will most probably follow the entrance of the moon into any of its *quarters*, and that so near the truth as to be seldom or never found to fail.

MOON. TIME OF CHANGE. If the New Moon—the First Quarter—the Full Moon—or the last Quarter happens.	IN SUMMER.	IN WINTER.
Between midnight and two in the morning.	Fair.	hard frost unless the wind be S. or W.
—— 2 and 4 morning.	cold with frequent showers.	snow and stormy.
—— 4 and 6 "	rain.	rain.
—— 6 and 8 "	wind and rain.	stormy.
—— 8 and 10 "	changeable.	cold rain, if wind W.; snow if E.
—— 10 and 12 "	frequent showers.	cold and high wind.
At 12 o'clock at noon and two P. M.	very rainy.	snow or rain.
Between 2 and 4 afternoon.	changeable.	fair and mild.
—— 4 and 6	fair.	fair.
—— 6 and 8	fair if wind N. W.; rainy if S. or S. W.	fair and frosty if wind N. or N. E.; ra. or sn. if S. or S. W.
—— 8 and 10 "	ditto.	ditto.
—— 10 and midnight.	fair.	fair and frosty.

Observations.

1. The nearer the time of the moon's change,

first quarter, full and last quarter, are to midnight, the fairer will the weather be during the seven days following.

2. The space for this calculation occupies from ten at night till two next morning.

3. The nearer to mid-day, or noon, the phases of the moon happen, the more foul or wet weather may be expected during the next seven days.

4. The space for this calculation occupies from ten in the forenoon to two in the afternoon. These observations refer principally to summer, though they affect spring and autumn nearly in the same ratio.

5. The moon's change,—first quarter;—full,—and last quarter, happening during six of the afternoon hours, i. e. from four to ten, may be followed by fair weather; but this is mostly dependent on the wind, as it is noted in the Table.

6. Though the weather, from a variety of irregular causes, is more uncertain in the latter part of autumn, the whole of winter, and the beginning of spring; yet, in the main, the above observations will apply to those periods also.

7. To prognosticate correctly, especially in those cases where the *wind* is concerned, the observer should be in sight of a good *vane*, where the four cardinal points of the heavens are correctly placed. With this precaution he will scarcely ever be deceived in depending on the Table.

It is said that the late Dr. Darwin, having made an appointment to take a country jaunt with some friends on the ensuing day; but perceiving that the weather would be unfavorable, sent as an excuse for not keeping his promise, a poetical epistle containing an enumeration of *most* of *the signs* of *approaching ill weather.*—I have *enlarged* these by adding several new ones, and remodelling others; and subjoin it as very useful, and a thing easy to be remembered.

Signs of approaching foul weather.

The *hollow winds* begin to blow;
The *clouds look black,* the *glass is low;*
The *soot falls down,* the *spaniels sleep;*
And *spiders* from their *cobwebs peep.*
Last night the *sun* went *pale to bed;*
The *moon* in *haloes* hid her head.
The boding shepherd heaves a sigh,
For see, a *rainbow* spans the sky.
The *walls are damp,* the *ditches smell,*
Closed is the pink-eyed *pimpernell.*
Hark! how the *chairs* and *tables crack,*
Old BETTY'S *joints* are on the rack:
Her *corns* with *shooting pains* torment her,
And to her bed untimely sent her.
Loud *quack the ducks,* the *sea-fowl cry,*
The *distant hills* are *looking nigh.*
How restless are the *snorting swine!*
The *busy flies* disturb the *kine.*
Low o'er the *grass* the *swallow wings.*
The *cricket,* too, how *sharp he sings!*
Puss on the hearth, with *velvet paws,*
Sits *wiping* o'er her *whiskered jaws.*
The *smoke* from *chimneys right ascends;*
Then spreading, *back to earth it bends.*
The *wind* unsteady *veers around,*
Or settling in the *south is found.*
Through the clear stream the *fishes rise,*
And *nimbly catch* the incautious *flies.*
The *glow worms,* numerous, clear and bright,
Illumed the *dewy hill* last night.
At dusk the squalid *toad* was seen,
Like *quadruped,* stalk o'er the green.
The *whirling wind* the dust obeys,
And in the *rapid eddy* plays.
The *frog* has changed his *yellow vest,*
And in a *russet coat* is dressed.
The *sky is green,* the air is still:
The *mellow* blackbird's voice is shrill.
The *dog,* so altered is his taste,
Quits mutton bones, on *grass* to feast.
Behold the *rooks,* how odd their flight,
They imitate the *gliding kite,*
And seem *precipitate to fall,*
As if they felt the piercing ball.
The *tender colts on back do lie,*
Nor heed the traveller passing by.
In *fiery red* the *sun* doth *rise,*
Then *wades through clouds* to mount the skies.
'Twill *surely rain,* we see't with sorrow,
No *working in the fields to-morrow.*

Hoping that this paper will be of some use to your country readers, I am, dear sir, yours truly,

ADAM CLARKE.

REMARKS ON DR. CLARKE'S WEATHER TABLE.

To the Editor of the Farmers' Register.

I now comply with your request, in sending you for publication, a copy of the Weather Table which was published in the New England Farmer, in December, 1830, with the remarks, &c. annexed. The table will speak for itself; but as you wished my observations relative to its correctness, and as I have had the table since 1830, and noticed particularly how far it was correct, I now give you a few of them. Judging from the observations of seven years, I can truly say no certain reliance can be placed on the rules in general; but still the table will be found more often correct than otherwise in its prognostics of *wet* weather. I am now writing Monday evening, the 4th of June, and it is raining and blowing most severely. It rained on Saturday, and has been cloudy and moist ever since, and now we have a severe storm, which promises to last some hours. Well, by the Almanac, the first quarter of the moon was on the 31st May, Thursday, 25 minutes past 2 o'clock in the morning.

The Weather Table says, that the weather 7 days from Thursday morning, 25 minutes past 2 o'clock, would be on the average cold, with frequent showers. It is cool, and we have had rain before the present violent storm, and the weather thus far has nearly corresponded with the prognostic. It has corresponded as to cool rainy weather, and it will rarely be found to answer to the prognostics in the table more correctly.

My observations have convinced me, that in the summer season there is much more reliance to be placed on the table than at any other season. If any change, quartering, &c. of the moon takes place near 12 o'clock in the day, I have never known it to fail to rain copiously some time in the course of the next 7 days, and most frequently the season is a wet one during those days. If, however, it rains copiously a day or two before such change, occasional showers only occur during the period. The change of the moon on the 23d day of May last, between 11 and 12 o'clock in the day, was preceded by much rain, and during the 7 days following we had but little rain, although the weather was moist, with occasional showers; and the weather is now more like what the change of the moon on the 23d of May prognosticated. I have thus far found the table much more correct in respect to rainy than as to clear weather. I remember that during, I think, the winter of 1837, the changes, &c. of the moon for a month, indicated wet weather according to the table. We had much rain and no clear weather for three weeks, but the fourth week was clear, although rain was indicated. It will not require very long observations for any person to be convinced, that the changes, &c. of the moon between 2 o'clock in the morning and noon, are much more frequently followed by rain than the evening changes. I think it will also be found, that in the fall and winter the north-east winds accompany the rains in *this state*, instead of the south-west winds spoken of in the table. Being a farmer on a small scale, I have found from sad experience, that for the last five or six years we have had a spell of very wet weather between the 31st of May and the 10th of June, and four days of such weather have already passed this month. The May wheat will probably be much injured, if not destroyed by the rust, in consequence of this weather. If, however, the season was not so backward, the May wheat would be past danger; for some few years since, some crops of that wheat were cut in this neighborhood on the 26th May. Much of it is now in bloom.

In closing my remarks, I have this to say about the weather table. In the summer season, it will often assist the farmer who will attentively observe the winds and the clouds, in judging as to the probability of rainy weather while about to cure his hay and his fodder, &c. A. B. S.

June 4th, 1838.

For the Farmers' Register.

EASTERN SHORE RAILROAD.

Sir—As much with a view to the spirit, as the letter of **** ****, from the Eastern Shore of Maryland, and as to a general discussion of the subject, I address you. The Eastern Shore railroad is to cost, for 118 miles, but $8541 per mile, and, with all the insinuations to the contrary, will not, agreeably to the description given of the ground, cost more than $10,000 per mile; at the same time it will enjoy a prospect of its reasonable share of the 50,000 travellers passing annually from north to south. Fifty thousand, did I say? rather 500,000; for, before ten years shall have elapsed, a number nearer to 500,000, than to 50,000, will pass it. In short, there will be among those who "travel by land *or* by water," sufficient to pay both road and steamers, and to repress feelings like those which have prompted this tilt against the former; for that there will be ample room for both, there is not the slightest doubt.

But how does the Eastern Shore writer sustain himself? He thinks Engineer Kearney's notion of Tangier quite out of the question; forgets that, as in the case of Philadelphia, it may possibly furnish an "excellent winter harbor" for Baltimore, and the probability which exists of the ships availing themselves of that harbor, instead of waiting in Hampton Roads "for a thaw." I think that, were I a Baltimorean, I should hail the project with pleasure; inasmuch as with —— miles back carriage from Elkton, it would give my fellow citizens the same chance of having their merchandise in winter, as Philadelphia. That city, it seems, projects "a railroad from the capes, to strike the railroad at Wilmington, (note A;) and, when this shall be accomplished, foreign goods can be transported to those cities (P. and W.) and cargoes carried by the return cars. By these means Jack Tar may be kept *constantly* at sea, free from the temptations and corruptions of the city, and *perhaps* Philadelphia may regain her commercial ascendency in the country." I cannot see why these arguments, will not as fully and as forcibly apply to Baltimore, as to Philadelphia; and, according to **** ****'s own showing, infinitely more so; for, without the Eastern Shore road, the trade of north Maryland, during the season of interruption, in a great degree, will pass to Pennsylvania. Besides, trade at all times will seek that place where supplies arrive without interruption.

Of the facilities of Tangier as a harbor, I am ignorant; but I had thought some of the British men of war had made good use of it during the last war, and as to the sneers of **** **** relative to "the musquitoes and the marshes," and "the gloomy Siberian forests," they still more strongly enforce on my mind the value of the improvement. It is to form a link in the great chain of coast railroad; (of another from Wilmington to Charleston they begin to speak.) It is to pass through a country requiring it, and thus the services the road may render are incalculable.

In page 744, of your 5th volume, and page 2 of the 6th, I see what is doing for Jersey, by means of marl, and what may be done for Maryland and Delaware, by means of lime; and as the upper Delawares are now boring for finding marl daily, I do not know whether a similar result may not be witnessed on lower Delaware, Accomac, and Northampton. I would observe, I am ignorant of localities, and without good maps; but, I do not fear being found in any grievous error, as my general ground is so solid.

As to *all* the routes from the south, and *vice versa*, there will be room enough, and travel enough, for the whole of them; but, as to "the most eligible one" being by "Richmond, Washington, and Baltimore," **** **** is mistaken, unless he confines himself to those who wish to loiter and spend money in taverns, or seek office at Washington. He allows that three hours would be saved from Portsmouth to Philadelphia, (note B). It is 85 miles by water to Tangier, and may be run in 6 or 7 hours. Doubtless, ere the road is completed, cars will travel with perfect safety, at the rate of 20 miles an hour, and this brings you to Wilmington in 12 or 13—so that I greatly suspect more than three hours will be saved in time; and I know that thrice, or more than thrice that number will be saved in dollars—and especially to families. Of personal conveniences I am silent.

As to "no art" being able to improve "the Siberian forest of Delaware" it weighs as much with me as the ultimate and prophetic clause of the communication. Of the correctness of both, I am in great doubt. Of the powers of the writer in prophecy, a full proof is *now* (thank Heaven!) to be had as to Atlantic steamer navigation; and, perhaps, ere these lines can appear in print, the return of the Sirius and Great Western will give the *coup-de-grace* to all this sort of vaticination. The pious, the philanthrophic, the philosophic, the political, the mercantile and the mechanical classes will all join, and join most heartily, in prayer for their success.

However, I would add, that an experience of more than half a century has thoroughly and conscientiously answered me, that in an active and enterprising community, (and some acquaintance with such a society as that of the United States has more impressively implanted it on my mind,) there is not the slightest doubt, that, like the Bridgewater canal and the Liverpool and Manchester railroad, *every* road projected in Virginia, will not only *directly* pay the proprietors a large interest, but *indirectly*, to the mass of society, a most enormous profit. "The value of every farm, consequently the wealth, and *perhaps the strength* of a country, greatly depend on an easy and uninterrupted communication by good roads." *(Rees' Cy.)* Of course there is no individual in Virginia, who is not concerned in opening roads either in his own or any other sections; and whether the road be from Abingdon to Winchester, or to Lynchburg, from the Roanoke to the Ohio, or the Kanawha to the James or the Appomatox, from Raleigh, from Wilmington, or from Fayetteville—every one of them will tend to augment her trade, foster her agriculture, and increase the general income of the state—of course, the real value of her landed property—and perhaps be the means, in 1850, of rescuing her from the condition, as to representation in Congress, in which the census of 1840 *must* leave her. Nor has *any* section of the country any thing whatever to fear from roads coming from north or south. The wheels of commerce should revolve with rapidity. Unlike that of fortune, they confer benefit at every turn. This we are all taught by the experience of the last century. Louis XIV. and George II. set a glorious example in France and Great Britain. They were great road-makers

In a country like that of the United States, there is not, nor will there ever be, one highway "of preference," that will "beggar" the other: a sentiment, I regret to see promulgated, and especially from such a state as Maryland; especially as there will be one and one great use for the Eastern Shore railroad. It will form a link in a great chain. It is necessary for the conveyance of the mail *directly* from New York, &c. to the south and south-west. As soon as it is completed, letters will rapidly proceed thither, passing through Raleigh, Columbia, and Augusta. as well as at Wilmington and Charleston. Express mails will be put down; and as soon as others, equally interested, choose to act, no more horses will be killed in carrying presidential messages at extra sessions. Here will be a difficulty, and indeed a difficulty. However, it will be removed when responsible engineers shall attend to their own business, and do not permit their journeymen, and perhaps journeymen looking forward to an interest in the contract to be made on the ground they pointed out, to run roads through morasses; and at an expense *per mile*, equal altogether to the fee simple value of the farms through which they pass; roads which, if laid out in a circuitous way, would not only, 1st. have been better sited; 2d. would have increased the value of land that required it; 3. would have not only furnished a market for wood, but wood for a market, where in winter it is sold for from \$4 50 to \$7 00 per cord; 4. would, perhaps, have partially rendered the road useful and usable to two, instead of one section of country; for, as you observe, "to adopt the route which will command the most transportation, and yield the most profitable dividends, is a consideration of still more importance than choosing the best (shortest) and most practicable route for a railway;" 5. would not have cost a dollar more—perhaps not as much. Dr. Howard pointed out one of 156 miles for the Charleston and Hamburg railroad. The company, under would-be-wiser advice, ran a straight line of 136. It spent double the money that was necessary, and has now to pay for embankment, as much or more than the whole of his route would have originally cost.

As to any partiality you are charged to have shown to the Petersburg road, you may refer for your exculpation to "Smeaton," at page 622 of Vol. II, of the Register, where the conduct of the Richmond and Petersburg delegations in the house of delegates was discussed, and their opposition to the Portsmouth and Roanoke road condemned. Have not both succeeded, admirably succeeded? The animadversion on their "*powerful scrutiny—their searching sagacity*"—was intended to be severe. But, I fear, "my lords of Norfolk" do not superabound with that liberality of courteousness they expect to receive, and indeed do receive from others. G. L. C.

NOTES.

Note A.—By what route? Why cannot the Eastern Shore railroad be so run as to serve Philadelphia and Tangier? The maps do not show on which side the Breakwater is constructing, and I forget the position.

Note B.—The fact is, that Richmond, Washington, and Baltimore are avoided as much as possible on account of their expense. Philadelphia is not a cheap, but it is a comfortable place. There are two cheap villages in its vicinity. The great object is to reach Philadelphia, &c., &c. There they can see the world, and thence they take their departure; "to various ways they run, &c." The same reasons take so many passengers direct from Charleston to New York. But a railroad into the mountains of Virginia would produce the same effect. Well would it be, if that and more were attempted. New York borrowed \$7,000,000 for her canal. In 20 years her productive public property was increased from \$2,193,617 to \$22,157,142. The revenue from \$419,907 to \$1,413,846. On public buildings \$500,000 were expended. The school and literature funds were doubled. The state tax discontinued; the people relieved from taxation. How terrible then are the effects of the national debt?

SUBTERRANEAN TRAVELLING.

The line of railway between Lyons and St. Etienne, the largest manufacturing town and the richest coal district in France, is only 34 miles in length; yet, such is the unevenness of the country, and so great has been the anxiety of the engineers to preserve as complete a level as possible, that there are actually no less than *twenty tunnels* between the two termini. One of these is a mile in length, while another, which is half a mile long, is carried under the bed of a river which crosses the line.—*Mechanics' Magazine.*

GEOLOGICAL ORIGIN AND FORMATION OF SOIL.

Extract from Dr. C. T. Jackson's Geological Survey of part of Maine.

Every attentive person must have observed, that solid rocks, exposed to the combined action of air, water, and different degrees of temperature, undergo decomposition and disintegration, so that they crumble into powder, and that some rocks decay more rapidly than others, owing to their structure, or mineralogical composition. If a rock is porous, or stratified in its structure, water infiltrates into it, and on freezing, expands with such power as to tear the surface of the rock to pieces, so that it readily crumbles. When fire runs through the forests, it heats the surface of the rocks, and by the irregular expansion produced, they are shivered into fragments.

The action of running water and friction of stones, also serve to grind the rocks into powder, by attrition of their surfaces, and the detritus is borne along by the streams, and deposited in low lands, or along their borders.

When a rock contains iron pyrites, or sulphuret of iron, that mineral, by the action of air and water, decomposes, and forms copperas, or sulphate of iron, and the sulphuric acid of that substance acts powerfully on some of the ingredients of the rock, and causes its rapid decomposition. Any person, who has been on Iron Mine Hill, in Gardiner, will fully understand how rapid is this operation, and may there see its results. The oxidizing power of the atmosphere, also, acts powerfully upon the surface of those rocks, which have for one of their components, the prot-oxides of the metals, iron and manganese, and as those oxides take up another portion of oxygen, they increase in bulk, become brown or black, and the stone falls into fragments.

These are a few of the causes now in action, which modify the solid crust of the globe, and it appears that their effects are far more important, than we might at first imagine. Whoever looks upon the muddy waters of the Mississippi, Ganges, Po, the Rhine, and the Rhone, or reads the calculations respecting the enormous quantity of matter brought down from the mountains by those rivers, will at once appreciate the modifying influence of those causes which are continually wearing down the solid matter that forms the mass of our mountains.

Geology teaches us, that such causes were formerly in more powerful operation, and that the ancient world was, from its infancy, subject to violent catastrophes accompanied by powerful inroads of the sea; oceanic currents and tumultuous waves having for many successive periods rushed over the land, and beaten the loftiest crags of the highest mountains. We should then naturally expect, that the earth would present ample testimony of the action of these powerful causes of disintegration of the rocks, and we do observe that a large portion of the loose materials upon the surface, bears proofs of aqueous action and mechanical abrasion. By those ancient convulsions, the detritus of the solid rocks was prepared, and forming the various soils, which we observe, the earth was rendered capable of yielding its rich stores of vegetation, on which a large proportion of the animated creatures depend for their food. From the foundation of the everlasting hills, the Creator began to prepare the world for the habitation of his noblest creature, man, and converted a portion of the solid rocks into soils, which were given as the field of human labor, and to the progenitor of our race it was commanded that he should till the soil.

If we take up a handful of earth, and examine it attentively, we shall readily discover such mineral ingredients, as denote the rocks from which it originated. Thus we discover in a soil numerous spangles of mica, grains of quartz, and white or brown earthy looking particles, which are felspar; besides which, we remark a considerable portion of fine brown powder, which being examined with a microscope is found to be composed of the same minerals, more finely pulverised, and mixed with the brown oxide of iron. It will be at once understood, that such a soil arises from the disintegration and decomposition of granite rocks, and that the oxide of iron was derived from the pyrites, or the prot-oxide of iron, contained in that rock.

A soil arising from the decomposition of gneiss, possesses similar characters, only the mica is more abundant.

Soils from mica slate are made up of a large proportion of mica, mixed with grains of quartz.

Sienite, and hornblende rock produce a dark brown soil, in which there is but little quartz, and a great deal of felspar, and decomposed hornblende.

Greenstone trap rocks form, by their decomposition, a brown soil, which contains pieces of the undecomposed rock, but the component minerals in the soil itself, are rarely so distinct as to be discoverable. This soil is a warm kind of loam, soft and spongy, easily compressed into smaller dimensions by the pressure of the hand, but not adhesive like clay. It is peculiarly adapted to the growth of potatoes. and is a luxuriant soil for most of our ordinary produce.

Slate-rocks form a soil of a blue color, in which numerous undecomposed fragments of the rock may be discovered. When transported by water, it is deposited in the state of tough blue clay.

Limestone forms various colored soils, according to the nature of the impurities it contains. They are generally of a light yellowish brown color, from admixture of a certain proportion of oxide of iron. This is especially the case with those soils derived from the argillo-ferruginous limestone.

Calcareous soils, if they are rich in carbonate of lime, may be distinguished by their effervescence with acids, and the quantity of this substance may be estimated by the loss of weight which indicates the proportion of carbonic acid, that has been expelled, and since the carbonic acid always occurs in the ratio of nearly 44 per cent. to 56 per cent. of lime, it is easy, by a proportional calculation, to ascertain the quantity of that mineral in the soil.

It more frequently happens, that there is so minute a quantity of carbonate of lime in the soil, as to require a minute chemical analysis for its detection, and few farmers have either leisure or means for such an operation. Examples of such analyses will be presently laid before you.

Talcose slate rocks, when decomposed, form a light brown soil, in which particles of the rock are discoverable, and, on analysis, a considerable quantity of the silicate of magnesia is found, which is one of the chief components of talc.

Red sandstone, on disintegration, forms soil composed almost entirely of grains of quartz, with oxide of iron, and clay, with a few spangles of undecomposed mica.

Grau-wacke, or conglomerate, when disintegrated, produces a light gray soil, full of smooth rounded pebbles, which originate from the undecomposed components of the rock.

Red porphyry is very slow of decomposition, and forms a bright red fine powder, filled with angular fragments of the rock.

I have thus distinguished and described the appearances which characterize those soils that arise immediately from the decay of solid rocks, and various characteristic specimens of each variety may be seen in the cabinet arranged for the use of the state.

Let us next consider how soils are distributed on the earth's surface, and see how their qualities depend upon their situation.

In various sections of this report may be seen recorded the proofs of diluvial transportation of rocks, far from their parent beds, and we have every reason to believe, that this removal was effected by a tremendous current of water, that swept over the state from the north 15° west, to the south 15° east, and we have adduced in testimony, that such was the direction of that current, numerous grooves, furrows, or scratches upon the surface of the solid rocks, in place, and have shown conclusively, that the rocks which we find thus transported, proved to be portions of ledges situated to the north of the localities where their scattered fragments are found.

It is a matter of surprise, that such enormous masses of rock should have been moved so far by an aqueous current; but, when it is remembered, that a rock does not weigh but half so much when immersed in water, as it does when weighed in air, owing to the support given it by the water around; and when we reflect on the fact, that a rock is still more powerfully supported under the pressure of deep water, it may be conceived, that, if a flood of water did once rush over the land, it might have removed large and weighty masses of rock, such as we find to have been the case.

From the observations made upon Mount Ktaadn, it is proved, that the current did rush over the summit of that lofty mountain, and consequently, the diluvial waters rose to the height of more than 5000 feet. Hence we are enabled to prove, that the ancient ocean, which rushed over the surface of the state, was at least a mile in depth, and its transporting power must have been greatly increased by its enormous pressure.

It will be readily conceived, that if solid rocks were moved from their native beds, and carried forward several miles, the finer particles of soil should have been transported to a still greater distance, so we find that the whole mass of loose materials on the surface has been removed southwardly, and the soil resting upon the surface of rocks, in place, is rarely, if ever, such as results from the decomposition of those rocks, but was evidently derived from those ledges which occur to the northward.

If an attentive observer examines the soil in the city of Portland, he will discover, at once, that it is made up from the detritus of granite and gneiss rocks, while the ledges in that city are wholly composed of the argillaceous, talcose, and mica slate-rocks, and granite and gneiss occur in great abundance to the northward.

All the markings on the surface of the rocks, and the scattered boulders of granite and gneiss, which abound in that soil, indicate its origin to have been in the north 15° or 20° west. I merely quote the above locality, on account of its being a spot where most persons will have occasion to examine the facts stated. The various sections of the state present ample illustration of the same fact, and every one who will take the trouble, may convince himself of its reality.

The tertiary deposits of clay, sand and marine shells, were evidently produced in tranquil water, since their strata indicate, by their situation, structure and beds of shells, that the clay was gradually and slowly deposited, allowing time for the propagation and growth of the various shell fish in its several layers. Not so was the diluvial matter deposited, for we find it to bear marks of sudden and violent transportation and deposition, the various pebbles, boulders and erratic blocks of stone being mixed in great confusion. I have formerly mentioned a locality, in Bangor, near the court-house, where, it would seem, there are proofs of a gradual subsidence of the diluvial current, the various particles becoming smaller, as we ascend the embankment, until we come to fine clay, which must have subsided from tranquil water.

We observe, then, that the tertiary deposits were cut through by the diluvial waters, which have excavated deep valleys, and heaped up long ridges called horse-backs, and the general direction of these valleys and ridges, coincides with the direction formerly indicated, as the course in which the current swept.

Although we are informed in the scriptures, that the deluge was ordained for the punishment of wicked men, it is certain, that there was mercy mingled with this dispensation, for the soils were comminuted, transported, and mixed in such a manner, that their qualities were improved, and rendered more suitable for the growth of plants, so that new and more fertile soils were prepared for coming generations, who literally *reap* advantage from the deluge.

Besides the ancient aqueous current, we see every day the action of water modifying the surface of the globe, transporting fine particles from the mountain-side, and depositing them in the valleys and along the margin of running streams. Especially during freshets, when the rivers burst their narrow confines, and spread out over the intervales, do we see rich deposits formed of *alluvial soil.*

Such currents, arising amid decomposing vegetable matters, transport an infinity of fine particles of such matter, and deposit it with the various earthy ingredients, which form our richest meadows, and luxuriant intervale soils. Thus are formed many of those bottom lands, which occur along the river-courses of the western states, and the banks of rivers in Maine, under similar circumstances, are found to be composed of like soils.

A river, coursing its way amid various rocks, carries down and deposits fine particles of every kind, which it meets with in its way.

If the rocks above are limestone, we shall have calcareous soil brought down and deposited by the river. So on the banks of the Aroostook, we find a rich alluvial soil, equalling in fertility the famed regions of the western states, and capable, even under a less genial clime, of producing crops of wheat and other grain, fully equal in abundance with any soils of which we have any records.

From the Genesee Farmer.

ROOTS VERSUS HAY.

We take the following from a report made to the Massachusetts Agricultural Society, by the Messrs. Colts of Pitsfield, Berkshire Co., and we do it to show the immense advantage made in substituting roots for hay in feeding cattle, as well as in the quantity of ground necessary to produce a given quantity of food.

The writer says—"My stock now consists of 1000 sheep, 8 young oxen, 6 cows, a pair of horses, and a single horse. I have raised this season for the use of my stock 5544 bushels of vegetables, and all to be grated and fed out with cut straw, the cattle constantly, the sheep one feed a day, which seems to be a necessary food in our long cold winters: it keeps them in health and also in flesh. As to the respective value of the vegetable food, the following statement will perhaps best exhibit it. I have commenced feeding and shall continue to feed,—

14 head of horned cattle with 20 lbs. of cut straw each per day, 4 cents for each 20 lbs., 56 cents. Also to each, 113 lbs. of roots grated, mixed with straw, 3 cents, 42 cents. And now allow 150 days for the season of feeding at 98 cents, is $147,00. The same stock would require 20 lbs. of hay each per day for 150 days; they would consume 42,000 lbs. equal to 21 tons; at the moderate price of $10 per ton $210,00. Balance in favor of root feed $63, and I am sure the stock will appear far better at the opening of the spring.

You will perceive that the respective value of vegetables for food is six cents a bushel, while hay is at ten, and straw at four. It may be said that there is some cost in preparing food; but this is more than compensated if properly done by the extra quantities of manure made."

Thus it appears that 20 lbs. of straw and 8 lbs. of roots mixed, afford more nutriment, and of course are more valuable than 20 lbs. of good hay, while the actual cost is much less. Fourteen or fifteen tons of roots are a moderate crop per acre, while the average of hay will fall considerably below two tons to the acre. The advantage in favor of the turnip is thus perfectly apparent, and the farmer who persists in mowing his twenty or forty acres, and keeping his stock on hay, when five or six of these same acres would furnish roots sufficient if mixed with the straw which might be grown on the remainder, to keep his animals far better than the hay, and leave the grain crop nearly as a clear profit, is clearly acting against his true interests. Again, we say to our farmers, you did well last year by so extensively entering upon the culture of roots; you will do better this year by greatly extending their cultivation.

From the Maine Farmer.

ACCOUNT CURRENT WITH A PIG.

Mr. Holmes;—I write that farmers and pork raisers may learn whether it is profitable to go largely into the business in this state or not. I have to this end opened an account current with a pig, for which I gave on the first of October at a month old, $1,50

Kept it until it was 16 months old, and then slaughtered it. 14 months of which time I kept it on raw and boiled potatoes—allowing it a peck a day; soon after weaning it did not need that amount—but it had milk or something as expensive; which results in his consuming, in the 14 months, 105 bushels—at 20 cents the bushel, amounts to 21,00

The month on its dam, and 14 months on potatoes, as above, brings it to 15 months old: the other month (for it was not slaughtered until 16 months old,) I kept him on Barley meal, at 67 cents the bushel, and it eat a half peck per day—which amounts, for the last month to 2,40

Tax 30

I charge nothing for attendance, risk, &c., being more than paid in offal and manure.

25,20

When slaughtered, it weighed three hundred pounds, which, at 8 cents the pound, brought me $24,00

Loss, 1,20

But if potatoes cost only ten cents per bushel, (which, in fact, is all they cost in raising,) then deduct from my charges against it 10,50

Making the profit $14,70.

Twelve such would give a profit of $176,40—a pretty item—and plenty of manure.

Some may suppose the pig was not so expensive as I have made it—that it would not eat a peck of potatoes a day, &c. &c If potatoes are worth more than I have put them at, pork should be too. I write, hoping to hear from others. No doubt September pigs are most profitable—they eat much less than earlier ones in winter; whereas early pigs eat, the first summer, what the later ones should have,—and on new year's day, when the September pigs are 16 months old, there will be very little difference in their size, if the late ones are kept warm the first winter. Some have supposed an early spring pig on the whole most profitable to kill on the first of January following; respecting which, I hope some farmer will communicate his views through the Maine Farmer.

Pen and Ink.

THE COMMERCIAL CONVENTION OF VIRGINIA.

In pursuance of the action and recommendation of the Commercial Convention held at Augusta, Ga., and the invitation and appointment made by the people of Norfolk, a convention of delegates, from various parts of Virginia, was held at Richmond, on the 13th inst., which adjourned on the 16th. There were more than 100 delegates present, and a large proportion of them from the country, and some from remote parts of the state. From the zeal displayed in the assembling and the debates of this body, and the newly excited and growing anxiety among the people in general for improving the present condition, and changing the course, of the foreign trade of Virginia, highly valuable results may be anticipated, even though the *direct* action of this convention may be of small importance. In fact, no practical measure for relief, or particular action, has been agreed on, to forward the great end in view, save the recommendation of an increase of banking capital. But even if the direct action were still less, the indirect operation of this and future conventions cannot fail to be most important and beneficial. What is now required, is to fan the patriotic excitement which has been kindled—to arouse every Virginian, and every Southron, both of town and country, to the evils that the south labors under—and the necessity, and the ready means offered by combined and proper action, for entire and permanent relief. Another convention is invited by a resolution of this meeting, to be held in Norfolk, on the 2d Wednesday in November. It is hoped that every Virginian who earnestly desires to place his country in her proper condition of commercial independence and prosperity, will lend his aid to the forming, and the proper and practical action of that meeting. The place of meeting—the noblest natural sea-port of the south, and the proper site for a great commercial entrepot, and a rich and populous city—will help much to show the advantages of Norfolk as a point for concentrating the foreign trade of Virginia, and to allay the petty jealousies of trade, which would divide, scatter, and thereby certainly destroy, the business and prosperity of the foreign trade of Virginia. We ardently hope that Richmond, Petersburg, and Fredericksburg will all enter separately and largely upon the direct import trade; but as ships can go to the wharves of neither of these towns, it will be decidedly better for their separate and particular interests, and still more so for the general interest of the commonwealth, that Norfolk should be the single point at which all ships bringing foreign goods shall meet, and thence distribute their cargoes to the various importers. The disadvantage of the small increased distance thus given to the passage of cargoes designed for other towns, would be scarcely worth notice, compared to the great advantages of all ships in the foreign trade being concentrated in the most convenient harbor, and where every article of supply, and facility for repairs and accommodation for ships, is ready, and will rapidly increase with the new demand. The jealousies and mistaken rivalships between the traders of the different towns of Virginia, have operated to counteract this proper condition of trade; and, in the pitiful contest, the interests of every party and every town has suffered. Let us, of other towns, concur heartily in permitting and aiding Norfolk to enjoy all her great natural advantages as a sea-port; and every other particular interest, and every portion, of this great state will profit by the prosperity of Norfolk, and the building up there the great sea-port and entrepot of southern trade.

We did not design to offer any thing more, at this time, than merely the results, and the principal report and resolution of the Convention—and even for this, we scarcely have space. Two important reports, one on the state of commerce, and the other, on that of the manufactures of Virginia, are yet to be prepared by different committees, and to be published hereafter; and these papers cannot fail to furnish much valuable information, and important aid to the great objects of the convention. These reports, or extracts from them, we hope will furnish appropriate matter to lay before the readers of the Farmers' Register.

Extracts from the proceedings of the Commercial Convention.

"Mr. Macfarland, (of Richmond,) from the Committee on Commerce, submitted the following report.

"The committee to whom it was referred by the Convention, to inquire into and report, whether the merchants of Virginia can import goods from foreign countries, on as good terms as the merchants of any of our sister states; and secondly, how the foreign trade of Virginia is affected by the want of capital, and in what manner the inconvenience under which it labors may be remedied—submit the following report:

"That the time allowed the committee for the consideration of a subject so comprehensive and interesting as the foreign commerce of the state, has been altogether too limited to enable it to perform its duty in a manner satisfactory to itself. There was not time for many inquiries which belong to such an investigation. The causes that have operated unfavorably to southern commerce, and denied to it the relative importance which was to have been expected from the enterprise and abundant elements of foreign trade of the south, could not be explored in a few hours of hurried consultation. The question especially addressed to the committee, and to which it has been under the necessity of confining its attention, has respect to the capacity of Virginia to maintain a foreign import trade. And if it shall appear not only that we can maintain such a trade, but are possessed of advantages which would enable us to enter into successful competition for it, the inquiry, how we may recover that trade, is the one immediately affecting the interests and business of the state.

"The question propounded in the resolution, namely, whether the merchants of Virginia can import from foreign countries on as good terms as the merchants of any of our sister states, may be answered confidently in the affirmative. They can so import. The markets of foreign countries, and the agency by which foregn traffic is performed, are as freely opened to Virginia capital and enterprise as to any other. From no part of our country can the operation of purchasing abroad, and of bringing home, be performed with more despatch, or at cheaper rates. This being conceded, as from the obvious nature of the proposition it must be, the question arises, whether it is the interest and policy of the state to foster and encourage a direct foreign import trade.

"Pursuing this inquiry, it is, in the first place, to be remarked, that Virginia has a large export trade—large when compared with the aggregate export of all the states. Her exports for three years ending with December, 1837, averaged $5,265,461. This, of course, gave her that amount of foreign capital, ready to be employed in whatsoever mode that was profitable. Yet, whilst she had it in her power, through the medium of her exports, to obtain directly, and at a reduced cost, the foreign productions demanded by her consumption, the course of trade hitherto has been to obtain those productions in northern cities; thereby receiving them through a circuitous channel, and at an enhanced cost. The average import for the period just referred to, has been less than one-seventh of her exports; and assuming that the difference between those two amounts has been expended in procuring at the north those foreign supplies, which her exports would have enabled her to procure directly from abroad, and assuming further, that the augmented cost of the former operation is equal to fifteen per centum, and we detect an annual loss of about $700,000 incurred by the state from her neglect of the import trade. But that sum is far below the actual annual loss; for fifteen per centum is an under estimate of the addition to the charges upon the foreign supplies coming through the indirect channel referred to, and the sum assumed to be invested in those supplies, is below the actual amount. The loss to the consumer of foreign supplies, so obtained, is equal at least to fifteen per cent. upon the amount of his purchases.

"Now, if any thing be needed to rouse the citizens of our state from the supineness which could overlook so enormous a tax upon its industry and resources, or reconcile them to it, it would seem to be the consideration, that it is with their own sterling money the importation is made, which they submit to receive at second hand at so ruinous a sacrifice. Again; the tonnage which is employed in carrying on the export commerce of the state would be more than adequate to the importation of all the foreign supplies demanded by our whole consumption. But, through the neglect of the import trade, the important advantages resulting from the employment of that tonnage have been lost to the state, and appropriated by those who have had the sagacity and enterprise to enlist it in their service. The amount of which loss is not to be estimated simply by the sacrifice of the benefits which would accrue to us, from the employment therein of domestic capital and labor, but by the sacrifice in addition of the associated trades and occupations that always attend upon the successful prosecution of any one important branch of business.

"Finally—for your committee must be content to suggest some of the prominent, rather than attempt to develop the numerous reasons which commend the import trade to the favor and patronage of our state—another, and not the least, consideration why a vigorous and persevering effort should be made to secure it, is, that it will have the effect of recovering the state from that dependence on northern markets, which has exposed us to suffer by their vicissitudes, without any direct participation in their prosperity.

"Upon the first view of the subject, the causes of the disparity between the amount of our export and import commerce, may not suggest themselves to inquirers generally. The former being large, as we have seen, involving all the facilities which are needed for making purchases abroad; the tonnage which carried out our staples being at hand to be employed in bringing in the productions for which it is to be exchanged; and the simple operation of barter being the natural and cheap mode of effecting that exchange, why is it that, at great pecuniary loss, our people rely upon others for productions that they could procure better by themselves? To answer this question fully, would lead the committee into an investigation, which they have not time to pursue. But among the most prominent causes that may be assigned, the capital required by the import trade, being greatly more than the capital necessary for the export [trade,] may be instanced as not the least influential. The export merchant, through the system of advances that universally prevails, has a large proportion of the capital employed in his purchases speedily restored to him, through the medium of a sterling bill which he is permitted to draw upon his consignee. The like rapidity of purchase and return is not enjoyed by the import merchant. He is exposed to the more tardy process of effecting a sale; and that sale is upon time. It is manifest, therefore, that the amount of capital requisite for the successful prosecution of the latter description of commerce is greatly beyond the capital which will suffice for the former. This consideration, in a great degree, accounts for the comparative languishing condition of the import trade, and the reluctance of our merchants to engage in it. The capital of few, comparatively, is adequate to its burthen; and the exigency resulting therefrom has not hitherto been met and provided for by the granting of those banking facilities, which a timely and earnest appeal to our legislature would doubtless have obtained. And this brings the committee to the consideration of the second resolution.

"It is the opinion of your committee, than an increase of banking facilities, so that the important interest which they now seek to recommend to general and spirited support, would readily obtain the accommodation of which it stands in need; accompanied by a patriotic determination of all classes of our citizens to support a course of domestic industry so auspicious to private and state wealth, comfort, and independence, and accompanied also by a judicious system of internal improvements, so that every section of our extended territory may be accommodated, and their rich resources developed, would secure to our state an extent of foreign commerce that would be the source of untold benefits to all classes of our people, and of power and consideration to our commonwealth."

Mr. Ruffin (of Petersburg) offered the following substitute for so much of the report as recommends the increase of banking capital.

"The desired change of the course of trade may be still more aided and secured by the action of the state government, which can be so powerfully wielded, according to the direction given, either for the benefit or the prostration of the best interests of the commonwealth. This may be done in various modes; but only one will be here specified, and recommended, as being the most obvious, and the most intimately connected with the practical operations of trade. This is, to increase the banking capital of Virginia to the amount required for the trade and business of the state, and at the same time to reform the system of banking, so as to guard as much as possible against the strong tendency of all such institutions to sacrifice the general interest of the country whenever the separate banking and stockholding interest can be thereby benefited. The reformation of banking operations is required at least as much as their extension; and both ought to be carried through together. Heretofore, Virginia has suffered her full share of the great evils of the general banking policy and operations of all the states, and has profited by but few of the advantages which a full participation in the direction of the operations would have secured to us, as they have, and in a great degree at our expense and loss, secured to the northern states. It is highly expedient that Virginia should enjoy more of the benefits of the banking system, and be better secured from its dangers and evils. Our state policy heretofore has been to refuse the good belonging to, or to be drawn from banking, and to receive, and submit to its worst evils, inflicted by the hands of others over whom we had no control, and whose gain was our loss."

This amendment was rejected, ayes 21, noes 60; and the report was then adopted, together with the following resolution.

"*Resolved*, That a vigorous and persevering effort be made to build up and sustain a large and increasing foreign import trade—that a committee of merchants be appointed, to sit after the adjournment of the Convention, to prepare an address to our fellow-citizens, unfolding the importance of such a trade, and the ready capacity of Virginia to obtain it—stating the support the trade will derive from an increase of banking facilities, under such restrictions and modifications as the wisdom of the legislature may devise, and from an addition to the banking capital, if the addition authorized by the existing laws shall be found, after a sufficient trial, to be inadequate to sustain and support the various interests of the commonwealth—and stating the aid the trade will derive from a judicious system of internal improvements; and that the legislature be respectfully requested to meet the advances of any neighboring state, who may have enacted laws to transport her products and merchandise into Virginia."

SHEEP GRAZING AMONG GROWING CORN.

To the Editor of the Farmers' Register.

Baltimore, June 20, 1838.

A few days since, I took a ride into the country with a friend, and, on passing a farm about twelve miles from the city, we observed a *flock of sheep quietly feeding in a corn-field.* The corn was about a foot high. Supposing we should be doing the owner a service, we took speedy occasion of informing him of it. He laughed, and said they would not hurt the corn; that the sheep were purposely kept in the field for the purpose of keeping down the blue grass, &c. On further conversation, he informed us that sheep will never touch the green or growing corn plant; that they must be very hungry if they do, &c. Having seen the sheep in his corn, and observed his undisturbed manner on being informed of the fact, I could not, of course, doubt the correctness of his theory; but I had never before known the fact, and thought there must be many others equally ignorant. If sheep will not only not injure the corn, but contribute to its culture by destroying the grass, and especially blue grass, I suppose it would be a great object with all corn-planters to have large flocks of them. I have mentioned the circumstance to several persons, who promise to try their sheep in their corn-fields. Pray, sir, is this old or new to you? If the former, say nothing about it; if the latter, let your readers have it.

GIDEON B. SMITH.

JAUFFRET'S NEW MANURE.

The conductor of the Gardener's Magazine speaks, in the May No., as follows of Jauffret's new manure, of which several notices have been lately published in the Farmers' Register.

"We have obtained satisfactory information from Paris respecting Jauffret's manure, and have also examined a heap of it prepared under the direction of M. Lozivy, at Durnsfield Lodge, near Wandsworth. The secret composition is given in detail in the *Repertory of Patent Inventions*, No. 51, p. 166; and we shall give it, with our opinion on the subject, and the facts on which that opinion is formed, in our next Number."

SINGULAR DISCOVERY OF A SUBTERRANEAN RIVER.

A singular discovery was made in Blaen-y-nant lead mines, near Mold, Flintshire, a few days ago. The workmen at the end of one of the levels were surprised, and obliged to run for their lives, in consequence of an immense rush of water suddenly bursting in upon them. After three days the water totally disappeared; and, on cautiously proceeding to the place, they found an opening of about four inches diameter, through which the water had issued. Hearing a sound as of a heavy run of water inside, they enlarged the aperture so as to admit of their passing through, and found that it was the bed of a subterraneous river, which in all probability affords the principal supply to the far-famed St. Winifred's Well, at Holywell, from which it is distant about twelve miles. The stream being then shallow, they explored it about sixty yards down, and were astonished to find several large caverns to the right and left, from the roofs and sides of which were suspended numerous and beautiful specimens of white spar or stalactites. The company are in high spirits, these appearances being considered favorable for a large lodgment of ore.—*Shrewsbury Chronicle.*

OF THE SUCKERS ON CORN.

Fonthill, May 2, 1838.

Dear Sir—I made a trial last summer of retaining the suckers on a part of my corn, which was sufficient to convince me, that nothing is gained by taking them away. From some cause last season, I saw more suckers shooting out from the roots of my manured corn, than I think I had observed before; and at the request of a gentleman, (to whom I had shown them, with the remark that I did not think that nature would, in relieving itself, do a substantial injury to any plant,) I preserved them, and watched their progress to maturity. They grew along with the parent stalks, (and becoming more and more detached as the season advanced, and as they acquired support from the roots which they sent out,) tasselled at the same time, and a great many, though not all, bore ears, at the proper places. And I have satisfied myself, at least, from the experiment, that by leaving the suckers, I made as much corn —certainly much more fodder—and saved the labor, in a busy season, of taking them away.

ON FEEDING HORSES ON PEASE, TO SAVE BLADES.

May 10*th*, 1838.

Mr. Editor—Agreeably to my promise, you will find below a piece on feeding horses on pease, to save blades. In 1836, I believed that I had not made as many blades, as I thought would serve my horses the year; and I had a fine crop of pease. I fed my horses on pease in the haums at night, and at 12 o'clock, and in the morning, on corn. I gave each horse half a bushel of pease in the haums. My horses got fat on them, and they did a great deal of work all the time. This piece may benefit the up-country planter, more than the down-country planter, as they have the advantage of marsh, that they can use by the first of May. But if the up-country planter's blades happen to give out by April, he has nothing that he can feed on in place of the blades, but oats, and they do not come in until the middle of June. I have been pursuing the same course with my horses this winter, though I had a plenty of blades, and I intend to continue to do it as long as I am a planter.

Hoping this may benefit some planters, I am yours, respectfully,

COLLETON.

PRUNING TREES.

A most injudicious system with regard to pruning trees appears to have been adopted by many of our farmers. A tree is neglected until it is comparatively old, and the top a dense mass of brush rather than properly directed branches, and then is attacked by the farmer with axe and saw, and nearly all the top cut off at a single operation. In the first place trees ought never to be left so long without pruning, where it is ever to be expected or required. The pruning should be made annually, and keep pace with their growth. In this way such ruinous loppings off of wood will be prevented, and the injuries that result from such a course be avoided.

When a fruit tree has grown with a thick bushy top, the bark of the central branches is tender, and when suddenly exposed to cold winds or hot sun, the effect cannot be otherwise than prejudicial. If the pruning is performed gradually, or annually, the bark is alike adapted to resist the influence of the seasons, and is not apt to become thick and tight, or tender and cracked. Perhaps the peach suffers more from injudicious pruning than almost any other tree; and where any considerable part of the top is cut off at once, it is most usually fatal. A mode which has been adopted to a considerable extent in the peach growing districts of New Jersey obviates in a great measure this difficulty, and also another serious one, the danger of the branches breaking when heavily laden with fruit. After the tree is planted where it is to grow, it is allowed to stand till it becomes well rooted, when it is cut off near the ground. Sprouts immediately spring up around the root, and of these five or six of the best situated ones are selected to remain, and the rest are carefully eradicated. These shoots are either budded, or suffered to grow up the natural fruit, according to the pleasure of the proprietor. The advantages derived from this course are these: these offshoots spread more laterally than would branches from a single trunk, and of course the sun acts upon every part of the branches more fully; and when they are loaded with fruit, they will fall to the ground in every direction, rendering the gathering of the fruit easy, and preventing the breaking down of the tree.

The experience of the best fruit-growers of the country, as well as the deductions of philosophy, would seem to point out the summer as the most suitable time to prune trees, as the material for covering the wounds is already elaborated, and will be immediately applied by the remaining branches. Professed nurserymen are more careful in this respect than the common farmer; pruning is by them carried on upon more of a system, and hence trees managed by them rarely are called to undergo such amputations of the top, as those where less attention is given them, and perhaps no pruning attempted. Much of the excellence of fruit, and the productiveness of the tree is dependent on pruning, and by commencing early, and following up a system carefully, such a shape may be given to the crown, and such a direction to the main branches, as most effectually to secure the advantages of sun and air.

From the Genesee Farmer.

BREEDING IN AND IN.

The judicious breeder will not too long confine himself to his own stock, unless it be very large. The breeding from too close affinities—the breeding *in and in* as it is called, though it has many advantages, to a certain extent, in the hands of most skilful and judicious breeders; though it may be pursued until the excellent form and quality of a breed is developed and established, and was the source whence sprung the superior cattle and sheep of Bakewell, and to some extent of the superior short horns of Mr. Colling; yet, to it also must be traced the speedy degeneracy—the absolute disappearance of the New Leicester cattle, and, in the hands of many an agriculturist, the impairment of the constitution of the New Leicester sheep.

Bakewell was a master spirit in breeding, and it cannot be denied, produced a breed of cattle worthy the efforts of such a skilful agriculturist. The principle on which he seemed to act was novel, bold, and for a time a successful one. Some of his cattle were extraordinary illustrations of the harmlessness of such a system, but he had a large stock on which to work, a veil of mystery was thrown over the most of his proceedings, and no one knew his occasional deviations from this rule, nor his skilful interposition of remoter affinities, when he saw, or apprehended danger.

But what has now become of the New Leicester or Bakewell cattle? where are they to be found? It was a bold and successful experiment, and seemed for a while to answer the most sanguine expectations of that skilful and spirited breeder.

In districts, in which experiments were carried on, it established a breed of cattle equalled by few; and it enabled the long horns to contend, and often successfully, with the heaviest and best of the middle horns. But no sooner had the master spirits of the day disappeared, than the character of the breed began imperceptibly to change. It had acquired a delicacy of constitution inconsistent with common management and keep; and it began slowly but undeniably to deteriorate. Many of them had been bred to a degree of refinement, that the propagation of the species was not always certain. The breed itself gradually diminished, in some places it almost disappeared. The reader may scarcely give credit to the assertion, but it is strictly true, that in 1833 there was not a single improved Leicester on the Dishley farm; nor a dozen within the circuit of as many miles. It would seem as if some strange convulsion of nature, or some murderous pestilence, had suddenly swept away the whole of this valuable breed.

The above remarks are in substance taken from that valuable treatise on British cattle, before alluded to. In Kentucky, though the principle of breeding *in and in* has met with general disapprobation, yet, it has been more or less practised by many breeders. To one of whom allusion will be made, not from unkindness, but merely for example, for he, like Mr. Bakewell of England, is a monument to illustrate the propriety of the practice. This breeder, (now less notorious) had, several years since, one of the finest herds of milking and breeding blooded cattle in Kentucky, and deservedly had high reputation as a breeder. But vainly imagining that they were far superior to all others, proper crossing was neglected, the stock began to diminish in size; many of them became hornless; and their constitutions were impaired, in consequence of which they suffered more from cold, in winter, and were more liable to disease, in summer; the murrain soon got among them, and played such sad havoc in one short season, that at present, only a few venerable animals remain of that once superior but ill-fated herd.

With this short digression we will again quote our valuable author. "It has therefore become a kind of principle with the agriculturist to effect a change in his stock every second or third year; and that change is most conveniently effected by introducing a new bull. This bull should be as nearly as possible of the same sort; coming from a similar pasturage and climate; but possessing no relationship—or at most a very distant one—not related to the stock to which he is introduced. He should bring with him every good point which the breeder has labored hard to produce in his stock; and if possible some improvement; and especially where the old stock may have been somewhat deficient; and most certainly he should have no manifest defect of form, and that most essential of all qualifications, a hardy constitution, should not be wanting." R. W. S.

STATE OF THE WHEAT-CROP.

The present wheat-crop throughout Virginia, and other adjacent states so far as we have heard, is the best, in quantity and quality combined, that has grown for many years—if not the best that has ever been made. Some partial disasters, on particular farms, have been suffered, from chinch-bug, hessian fly, or rust; but nothing worth naming as affecting the general crop of Virginia. A more considerable cause of diminution will be found in the circumstance that there is less surface now under wheat than a few years ago; as the repeated losses and failures of wheat have caused almost every farmer to withdraw some portion of his field (the part promising the least product,) from wheat-culture, and substituting oats or rye. The crop is now so far advanced in lower Virginia, that it may be considered out of danger, except from continued wet weather during the time for harvest; by which cause we have known one crop (in 1821) nearly lost, after it was ripe enough to be reaped. The weather now (June 25th) is very favorable.

Harvest was begun on some of the most highly improved marled land on James river on the 18th inst., with purple-straw wheat—which was as early as (what is called) May wheat, elsewhere, was ready for the scythe. There has been a predominance of cold weather for the time of year, through the last 60 days, or more, and the growth and ripening of wheat were every where more backward than usual. If the crop should prove as abundant as we now expect, it will be a most important means of restoring the commercial prosperity of the United States, and especially of Virginia, which has latterly been so wofully eclipsed.

There is also a prospect of good prices for, as well as good products of wheat. For crops to be delivered before August, at landings on James river (tide water,) $1.50 per bushel is offered; and sales have been made on these terms, by most of those who expect to be able to effect so early a delivery. Afterwards, prices must be considerably lower, unless there should be a failure of the European crop, and a consequent great foreign demand; neither of which contingencies is at all probable at this time. According to these views, every farmer should endeavor to get his crop to market as early as possible.—Ed. Far. Reg.

June 23d.

From the Farmer's Cabinet.

SUMMER PRUNING OF TREES.

"Experience is the best teacher."

The right time for pruning trees is after the first running of the sap, from the middle of June to the first week in July. The reasons for it are—in the first place, when a tree is in full leaf you can better judge what branches to remove, than when it is leafless. In the next, the wound heals over more kindly and effectually after summer trimming, than after winter or spring pruning; and lastly, suckers are not so like to shoot out after midsummer trimming, as if it was performed in the spring of the year. The writer of this has performed the operation extensively on a large number of trees of various kinds, the last week in June, with the greatest success, and has never seen a tree, in the least degree, injured by it. The practice is now becoming general among those who have the most knowledge of the subject, and it is hoped that those who are timid at departing from an old custom, will make a trial of it this season, on a scale proportionate to their faith, and rest assured diappointment will not follow the experiment.

Pyrus.

FLINT IN WHEAT.

The scoundrels who burn wheatstacks in the country leave behind them some curious chemical results. "Swing" is a grand experimentalist. There are found in the embers, lumps of coarse glass, which are the result of the fusion of the silica, or flint, which wheat straw in particular is found to contain in very considerable quantities.

ERRATA.

The following errata were caused by the illegible writing of the several pieces in which they occur:

No. 2, p. 78, col. 2, at end of 3d paragraph, for "*shown*," read "*slow.*"

No. 3, p. 164, col. 2, line 3 from bottom, for "*gents*," read "*goats.*"

No. 4, 202, col. 2, line 17 of editorial remarks, for "*extreme*," read "*extensive.*" This last error is corrected in part of the impression.

THE FARMERS' REGISTER.

VOL. VI. AUGUST 1, 1838. No. 5.

EDMUND RUFFIN, EDITOR AND PROPRIETOR.

From the New England Farmer.

LETTER FROM DR. D. STEBBINS, OF NORTHAMPTON, MASS., TO THE CONGRESSIONAL COMMITTEE ON AGRICULTURE.

Northampton, County of Hampshire, Mass., February 10, 1838.

I have received a communication from the committee on agriculture, dated Washington City, January 30, 1838, for answers to several interrogatories about the culture of the mulberry and sugar-beet. The committee must be aware that the silk-business of America is but in its infancy; yet, knowledge of the subject is constantly on the increase. Improvements are made from year to year, not only in the culture of the mulberry; but in the manufacture of the article of silk. Let it not, therefore, be thought wonderful, if it should be found necessary hereafter, to abandon our present opinion, practice of culture, and machinery used in the manufacture, for a better mode and more simple machinery, and so cheap as to take place of the domestic wheel, reel and loom. If, in either respect, any improvement can be made, Yankee perseverance and ingenuity will discover it.

The committee will please accept of the aid of Edward Church, Esq., of this place, who has long resided in France; and, while there, became very much interested in the subject of sugar from the beet; I presume that he possesses as much information on that subject, or even more, than almost any person in the United States, and have engaged him to reply to the subject of beet-sugar.

On the subject, or respecting the culture of the mulberry, it would afford me great pleasure to present the committee with an *infallible* mode of treatment, which would be applicable to every variety of climate, and the inconstancy of the weather for several years past. But so variable have been the seasons, that the successful mode of culture and protection of the tree during one year, has disappointed the cultivator the next year.

1. In reply to the first question : I began the examination of the mulberry business several years since; but did not commence the cultivation of the multicaulis until 1833, and ever since have carefully watched the progress.

2. Respecting *soil, situation* and *exposure;* I have found that our *poor, light, dry,* and even gravelly soil, is better adapted to the culture of the multicaulis, than our richest lands. The *location* or *situation,* should be high, or elevated above the danger of water collecting about the roots.

On such soils, although the trees would not attain the height of trees grown on rich land, yet the foliage would be more numerous; and the chance of having the trees ripen, or form hard wood for cuttings, and sustaining our winters, would be enhanced.

3. Respecting the *most valuable mulberry* for cultivation; its *capability* to endure the *cold* and *frost;* the *quantity* and *quality* of foliage; *labor* of culture, and *stripping.* These questions will be answered with reference to this climate; and will include not only my own observation and experience, but the experience of others of my acquaintance, in whose opinion I have the utmost confidence.

I commenced with the *Italian* white mulberry, and have used also the *black* and *red* mulberry; each of which requires good soil; no matter how rich. I found that, although the worms would feed well on these, yet they were equally fond of the multicaulis, which was selected for its large leaf, nutritious quality, and tender fibre, which the worms can eat, while the fibres or ribs of the white mulberry are so ligneous as not to be edible. Eighty pounds of multicaulis foliage are considered equal to one hundred pounds of the Italian white, for feeding worms.

The tree or shrub commonly known as the multicaulis, was found in a garden in *Manilla,* cultivated as a tree of ornament; and, to distinguish this from all other mulberries, is now called the *Manilla multicaulis,* and particularly to distinguish it from *another tree,* more deserving of *multicaulis,* on account of its capacity to produce more numerous stalks and branches.

Although the *Manilla multicaulis* has a very large leaf, grows rapidly, and the silk worm is fond of it; yet, in consequence of its rapid growth the stalks are often so green and tender, that, when overtaken by early frost, they are liable to be injured, before the wood has been sufficiently formed to endure cold and frost.

Nevertheless, the *Manilla* multicaulis is so valuable a tree, that experienced cultivators have told me that, if it should become necessary to take them up every autumn, protect them during winter, and re-set every spring, it would be much better than to cultivate the white mulberry; and that the culture of an acre of mulberry would require no more labor and expense than that required for an acre of Indian corn.

But there is another mulberry alluded to—the *Canton* multicaulis—so called from the place of its derivation, being the product of seed which the *Canton mission* were requested to procure, being considered the very best and most approved mulberry used by the Chinese, and is believed to be the first genuine seed ever imported into this or any other country. It was obtained under very favorable circumstances, such as have not often occurred; and the same mission have recently forwarded more seed for next spring's use.

That the *Canton* multicaulis is the true kind used by the Chinese, is made evident from a set of historical paintings from China, and from the seed growing at the foot of the stalk, different from other mulberries.

From the experience I have had, I concur in opinion with those who have cultivated the several kinds of mulberry, that the *Canton* multicaulis is deserving of the first consideration, and to be preferred to all others; not only on account of its equal capability of enduring cold and frost, but from the number, quality, and size of the leaf. Although not so large as the Manilla leaf, yet a leaf of the same size, is considered much heavier than the Manilla—some say double the weight.

I have cocoons in possession, made by worms which were fed exclusively on the foliage of the white mulberry; and another parcel fed exclusively upon the foliage of the *Canton*. The latter have a lustre and brilliancy far surpassing the former; and the difference is nearly as great as between the Merino and wool of native sheep.

It is the opinion of horticulturists and those best acquainted with the propagation of trees or plants from seeds, that trees from seed withstand the severity of climate better than trees propagated by any other mode.

Another circumstance occurred last autumn, in favor of the *Canton:* I had the *Canton* and *Manilla* trees, and another kind, called the *Asiatic* seedling, growing side-by-side in my garden, each having the same exposure to an untimely and severe frost, when the *Manilla* was much injured, the *Canton* and *Asiatic* escaped unhurt; and two other kinds, called the Chinese and Smyrna, were uninjured.

These seedlings, we hope, will be a most valuable acquisition to the list of mulberries adapted to the feeding of worms, and enduring the cold and frost; nevertheless, great caution is necessary in the use of imported seed; for instance, seed grown upon the multicaulis tree, will not produce a plant like the original tree; at least, it has so proved under my observation. The leaf is different in shape, and not one-fourth so large as the original; neither do the seeds produce trees which furnish a uniform leaf in shape or size. There is often deception in seed procured at foreign seed-stores; sometimes the vitality of the seed is destroyed, or otherwise injured by neglect. For these and other reasons which might be offered, purchasers of seed have been disappointed, and the mulberry cause injured; because they have expected too much, or that, by the seed of a certain *name*, they should obtain the genuine tree. The peach, apple, and some other trees, from seed or stone fruit, when planted, produce a great variety; perhaps not one seed in a thousand shall produce a tree, in all respects, like the original. It is advisable to have no dependence on the seed, but to procure trees which have developed the true character.

Having mentioned the *Canton* mulberry as first on the list, yet some, who do not know the Canton, would have the Manilla stand at the head of the list of the most valuable mulberries. The *Asiatic* and *Chinese* may be the next best, on account of their capability of enduring cold and frost; the leaf of which, in shape, resembles the *Canton*, but not so large; each of which, however, on account of the numerous buds on the stalks, may produce as much weight of foliage, and of as good quality, as the Manilla multicaulis of the same age. But should the Manilla multicaulis utterly fail of acclimation in this latitude, resort may be had to the *Canton*, *Asiatic*, *Chinese*, and some others which have been propagated from the seed, and give fair promise of adaptation to this climate.

In a more favored clime, the last year, these trees attained a much greater height and larger leaf, than in this place.

4. Respecting the *best mode* of cultivation, *stripping*, *value*, *expense*, and *profit*, of an acre of mulberry, I shall not only communicate my own experience, but that of the most skilful cultivators in this region.

In *this climate*, the culture, setting out mulberry roots, or cuttings, commences at the usual time of making our gardens, after the spring frosts, and when the earth has been suitably warmed by the sun—last April or beginning of May; and soon as the foliage has grown to the size of an apple-leaf, or the full size of the white mulberry leaf, (about the 15th or 20th of June,) the eggs may be brought out for hatching; and, if they can be kept back, so as to be hatched at different times, as the foliage multiplies, the cultivator will have the advantage of several crops in succession from the same lot of eggs—a much better way than to breed *in*-and-*in*, as it is called. Eggs may be preserved during winter in a cool place; freezing does not injure them; but before spring, they should be secured in glass bottles corked tight, to exclude the external air, and each bottle of eggs put into an ice-house, placed on a *cake* of *ice;* if set upon a shelf, they would hatch, even in an ice-house. Eggs thus secured, may be kept back, save much labor, time, and expense. As one class of worms are advanced, another can succeed them on the same shelves or hurdles. In this way, the same number of trees would feed double the usual quantity of worms.

In gathering the foliage, the buds must not be injured, nor the extreme ends of the limbs deprived of the leaves, leaving two or three leaves at the end untouched; commencing on one side of the field, and when once gone over, there will be a new crop of leaves ready at the place of beginning; and thus the foliage may be gathered several times from the same shrub or tree, whether the product of a root or cutting. I had roots and cuttings set out last spring, the foliage of which was gathered three or four times from the same trees, without injury; indeed the trees apparently grow better by having the leaves taken off so frequently, always leaving the buds uninjured, and the extreme ends of the branches without stripping. Instead of stripping the leaves, each leaf should be taken separate; if the bud should be injured, it would be spoiled for a cutting, or even foliage. Frequent defoliation of the mulberry does not injure it, although such treatment would spoil some other trees.

When trees are started from cuttings, it will often be found that a shoot will grow several inches before there is any root formed; in this case the support is derived from the atmosphere, instead of any assistance from the root, as is usual with other trees.

Vegetables of rapid growth are said to perspire their weight in twenty-four hours; this rapid evaporation or perspiration will account for so many cuttings failing to become trees; the leaves become discolored, wilt, and the plant is ruined. But to avoid this, let the cuttings be watered in dry weather, and take off the leaves until roots shall be formed.

Respecting the *cultivation*, the earth may be stirred or the trees hoed so frequently as to prevent the weeds growing; but not after the first of

August, that the trees may have opportunity to form wood; and the location must be so elevated and dry as to be out of the way of water setting near the plants.

Respecting the *value* of an acre set with mulberry, it depends on the price of the mulberry and number of trees set therein. If the trees are set $2\frac{1}{2}$ feet apart in the rows, and the rows 3 feet apart, an acre would take 5,808 trees, which at 25 cents each, would be worth $1,452. Some prefer to have the rows 4 feet apart, and 2 feet apart in the rows; in this case it would require 5,445 trees to the acre. But provided an acre of ground shall be set with cuttings, the rows 2 feet apart, and $1\frac{1}{2}$ foot apart in the rows, 14,520 cuttings might be set in an acre, which at $30 cost per 1,000 or 3 cents, would amount to $453 60, to stock an acre. It may be understood that a purchaser wishing to stock an acre of ground, the trees and cuttings could be purchased at a less price than above stated.

Taking into consideration the number of trees the most proper for an acre, and a reasonable price for the trees, the *average* price of an acre of land set with mulberries, including the land, might be worth from 750 to 1,000 dollars investment.

The *cultivation* of an acre of mulberry would, of itself, be no more than that of an acre of corn; but, including the *gathering* the leaves, *feeding* the worms, and *reeling* the silk, need not exceed 200 dollars. The *profits* of an acre of mulberry would depend upon the fidelity with which the worms are fed, and the quantity of raw silk made from the cocoons.

Some cultivators assert than an acre of ground set with mulberry will, the second year, produce foliage sufficient to feed 1,000,000 of worms, and that number of cocoons will make $333\frac{1}{2}$ lbs. of silk. I have no personal knowledge of one acre having been set apart for that purpose; but from experiments made with certain number of trees, in proportion to the acre, it has been ascertained that 100 lbs. of raw silk may be made from an acre the first year of setting out; and if the roots can be preserved without removal during the winter, a much greater quantity of foliage would be furnished, and, of course, a greater quantity of silk might be made the second and third year; so that the maximum might be 300 lbs. or more of silk to the acre. But assuming the minimum quantity, (100 lbs. from an acre,) it would yield the cultivator a greater profit than from any other product from the soil.

The last year I requested several cultivators to make thorough experiments to ascertain the *certain* profits of an acre. Only one, however, met the application with the precision desired. He, by strict economy of time, labor, and expense, although he gave *three* dollars per week and board, to two experienced females, as teachers in gathering foliage, feeding worms, and reeling silk, found that his silk cost him only *two dollars* the pound, and estimates his silk worth at least six to seven dollars the pound, on account of excellency of the reeling, for which he has the liberal bounty of the state, and also a premium from the Agricultural Society. The quantity and value of silk depend on the skill and perfection of reeling.

The value of *American* silk far exceeds the imported raw silk, not only in lustre, but strength of fibre, and the small comparative waste in the manufacture; and is probably worth 25 per cent. over the imported article of raw silk.

The same cultivator informs me that, the last year, being a year of experiment, attended with loss of time and expense, which he can avoid another year, he feels confident that he can hereafter make raw silk at $1 50 per pound.

5. Respecting the most valuable silk worm: Perhaps the large gray or black one-crop worm on all accounts is equal to any other. There sre several varieties of worms—one called the two-crop worm; but one good yield is worth more than two poor ones, with imperfect cocoons.

In China, where several crops are taken in succession, from hatching eggs of the preceding crop, it has been found that the quality of each succeeding crop of silk is deteriorated, and that silk grown in the elevated or northern regions of China, uniformly commands or obtains 20 per cent. more for any quantity of silk, than for silk grown in the warmer latitudes; and for the same reason that American silk is superior to that imported. It has been thought that the Chinese seldom or never export the silk grown in the cool regions, but that it is retained for the superior fabrics. Eggs, to be of good quality, must have the maturity of age. The usual time of hatching the first parcel of eggs, in *this climate*, is from the 15th to the 20th of June, or as soon as the mulberry leaves have a size to commence gathering. 3000 worms, (or even 2000 or 2400, if well attended,) will make cocoons sufficient for one pound of silk.

The *quantity*, *quality* and *value*, and *market* of cocoons, depend very much on the attention of feeding the worms, ventilation and cleanliness of the cocoonery; in cold seasons the worms do not make so perfect cocoons as when the weather is mild during the time of feeding.

As to a market for cocoons, the several silk factories and reeling establishments will readily purchase or reel them on hire; and that the producer should receive the benefit of good cocoons, instead of purchasing by the pound, a fair price would be given for any quantity yielding a pound of silk. The cultivator must, therefore, see the propriety of so faithfully feeding the worms as to produce hard and sound cocoons.

But the cultivator would derive the greatest profit by reeling his own cocoons, as every family might do with very little expense.

6. The legislature of Massachusetts give a generous bounty to encourage the growth of silk—about sufficient to cover all the expense of gathering the leaves, feeding the worms, and reeling the silk; so that every pound of silk raised and made in Massachusetts may be considered a clear profit to the cultivator; rent of the land, taxes, and interest of investment not included. Nevertheless, even these items may be overcome in a very short time.

The legislature of Massachusetts offer a bounty, on the manufacture of beets into sugar, of three cents on the pound—probably sufficient to cover the expense of manufacture.

Finally. On the subject of mulberry and silk, although it has engrossed much of my time and attention under the most anxious solicitude for its success, and with the persuasion that it would ultimately be found the most lucrative business which the cultivator of the soil could pursue, yet, that any certain infallible rules and modes of procedure, can at this early stage of the business be pointed out as applicable to all future years, I do not believe. *But there must be a starting point*, and we must be guided by the best light now before us. It is with great diffidence I enter on the subject to be laid before the committee of Congress, being aware that I may differ in *sentiment*, *practice*, and *opinion* from other more experienced cultivators, and that it may be found expedient hereafter to relinquish present and adopt new measures. But when intelligence shall be received and laid before the committee from various sections of the United States, I feel confident that the committee will find matter to report favorably on the culture of silk in this country.

Respectfully yours,
DANIEL STEBBINS.

To the honorable Chairman of the Committee on Agriculture, Washington City.

P. S.—There are in this place, two large silk factories doing a profitable business.

From the Franklin Farmer.

BOOKS ON AGRICULTURE, FOR SCHOOL BOYS.

We have thought the cause of agricultural improvement would be greatly promoted by the publication of a series of elementary books on agriculture, designed for the use of the schoolboy. Why should not our children have facilities for the acquisition of knowledge applicable to this pursuit as well as on less useful ones? If education is designed to fit us to engage in the practical duties of life, why is it that the most important of all earthly subjects, and one which occupies the labors of a vast majority of our people, is not the leading object of the schoolboy's education? We have elementary books on every other subject; we have schools wherein are taught the rudiments of every science, schools of law, medicine, divinity, of fighting, dancing, and of every thing but of agriculture. There is something wrong in the national practice on this subject. We ought to give to the most important subjects, the highest degree of attention—we must graduate various branches of education, by the standard of their relative importance, and give to those having the nearest relation to our most important interests, the greatest share of favor. We ought to have the principles of husbandry taught in every common school and a chair of agriculture endowed in every college. And we think the first step to the introduction of this new branch of education is. to have the necessary elementary schoolbooks. We have many men in our country, eminently capable of compiling such works and adapting them precisely to the capacity of the schoolboy. And he who would prepare a set of works on agriculture for the use of schools, such as would give to the boys of the country destined for the pursuits of husbandry, a thorough knowledge of the principles and the outlines of the practice of agriculture, would do more for the general good and for his own literary fame, than in any other walk of science or learning. Let it not be supposed that we decry other branches of science or learning. We are in favor of all; and especially those which contribute useful aids in the practical labors of life. We would render all subservient to man's use; and it is only in this view that they should be appreciated. But it is admitted on all hands, that agriculture is the most universal, the most dignified, the most congenial, virtuous and productive pursuit of mankind—the substratum of all other pursuits—the life and soul of commerce and manufactures—the mother of the arts and sciences—the basis of civilization; and we insist, it is *not* seeking too much when we seek to give to her own child, the husbandman, a higher grade of education. Whatever description of knowledge, relates nearly or remotely, to the multifarious labors of the agriculturist, should be an object of his study and constitute a portion of his exercises at the primary school and the college, and employ his reflections in all the riper years of after life. One of the most absurd and mischievous errors of the day, is that of the father, who gives to the son destined for a farmer, an education inferior to that he bestows upon the one destined for a profession. The husbandman deserves a better education than a lawyer, or a doctor; because his occupation requires the exercise of more knowledge; but it is too generally the case, that he is only allowed some snatched intervals between the crops, "to learn to read, write and cipher"—and this is deemed education enough for a farmer! Oh, what a wretched, miserable error is this—what a foe to the improvement and dignity of the class! It ought, it must be banished, and the practice which results from it abolished, and a wiser and better one substituted. Now, however the remark may seem to censure the general opinion and practice on this subject, and although we may be even ridiculed by many farmers themselves, for the apparent ultraism of the sentiment, we are bold to declare, nevertheless, that the farmer *has need* of a better education, and he actually more often requires the aid of more various branches of science, in his ramified operations, than the member of *any* profession; and we sincerely believe, that if any discrimination should be made in the education of two sons, one destined for a farmer and the other for a profession, it should be in favor of the former. Let us not be misunderstood—the boy destined for a profession or trade, should be thoroughly educated in all branches pertaining to his distinct calling; while the boy intended for a farmer, should be thoroughly instructed in all the principles to which the intelligent and scientific agriculturist stands indebted for the successful result of his labors. We could easily show that these principles are drawn from a wider range of sciences, than are necessary to be consulted by one destined for any of the so-styled *learned* professions; and consequently it would be shown, that the husbandman needs a more extended education. A young man preparing for the bar, is ready to enter upon his legal studies, on attaining some smattering of Latin (or it may be Greek;) and many do not even go thus far, before taking up Blackstone. A short course of reading elementary works on the principles and practice of law, and the student enters on the practical field of his profession. The physician requires more preparation to qualify him for practice. He too, learns the dead languages and studies the principles and practice of his art, but those principles involve a knowledge of various abstract sciences and he is constrained to invoke the aid of anatomy, physiology, chemistry, mineralogy, botany, &c. &c., before he enters upon the practice of his profession. We are speaking of those studies only as they relate to the *professional* qualifications of the student, and of course we are not to be understood, as denying either the possession or the importance, of other branches of learning, to professional men. They, as well as agriculturists and others, in their social and political relations to community, are equally required to discharge the duties of *citizens;* and we hold that all classes should avail themselves of every accomplishment which learning or science can bestow, in aid of the performance of those high duties. But we need not array comparisons or illustrations on the subject; our opinions may be presented at one view. We would give to every one, of whatever pursuit, precisely the education adapted to it—and it should be thorough and perfect in all its branches, or at least so far as any or all the branches related to the peculiar pursuit adopted by the student. It should thus qualify him for the intelligent prosecution of the labors of his life and ensure his complete success. It would render the farmer as illustrious, and certainly as useful, in his sphere, as the profoundest statesman or professor. But the subject is too interesting to be treated satisfactorily in the narrow limits to which we are circumscribed; and we mean to pursue it. In the meantime, we submit to the board of education and to the commissioners of common schools, the propriety of early considering the importance of adopting a series of agricultural works, as text books in the schools about to be put in operation, under the excellent common school law of the state. They may do incalculable good to the children of Kentucky, which will flow to other generations, and they may render the system far more useful and effective, by seasonably directing their earnest attention to the subject.

From the Farmers' Cabinet.

PEACH PROSPECT.

We are happy to learn from Delaware, now becoming celebrated for its *fine peaches*, that although the cold weather and frosts have been most trying on the young fruit, and much of it injured, that there is yet *enough spared* to promise a fine crop—if no future frosts should occur to nip the tender blossoms just bursting from the bud. The great success of Messrs. Ridgeway and Reeves, near Delaware City, (and who does not remember their fine and luscious peaches of last summer?) will soon be followed by other equally enterprising gentlemen of Delaware and this city who have gone largely into the business.

On the Union Farms, near Wilmington, owned, we understand, by Dr. Thomson of that place, and Mr. M. Eayre of this city, we learn that about 100 acres immediately on the river Delaware, are now flourishing in peach trees, and that about one half will bear this year, and that by a late arrangement our esteemed fellow-citizen, I. Reeves, for whom peaches will always grow, has become a partner with these gentlemen in their large concern. Philip Reybold, Esq., the efficient President of the Delaware Agricultural Society, has also, we understand, set out this spring a large orchard. We sincerely wish all these gentlemen the success they merit. Some of the fine peach districts of Jersey, seem of late years to have lost their power of producing, and continuing long-lived, the tree that produces this best, in its season, of all fruits. We should like to hear from some of our Jersey subscribers, if they can give us the reason, why it is so—and if any clue has yet been found into that most insidious and fatal disease to the peach tree, *the yellows?* We hope this hint will be kindly taken, and that all the information that can be imparted to us may be given for the benefit of the readers of the Cabinet, on the interesting subject of rearing and of prolonging the existence of the peach tree. A full and generous supply of this luscious and wholesome fruit, is a matter of great interest and luxury to every one, and our populous districts and cities should not hesitate to hold out the highest premiums and inducements to those who propagate fruit and supply our markets with the finest varieties.

From the Farmers' Cabinet.

USE OF LIME.

Lockhart, in his Life of Sir Walter Scott, relates the following anecdote.

'There see'—he continued, 'that farm there, at the foot of the hill, is occupied by a respectable enough tenant of mine; I told him I had a great desire for him to try the effects of lime on his land. He said he doubted its success, and could not venture to risk so much money as it would cost. Well, said I, fair enough; but as I wish to have the experiment tried, you shall have the lime for the mere carting; you may send to the place where it is to be bought, and at the term day you shall strike off the whole value of the lime from the rent due to me. When the day came, my friend the farmer came with his whole rent, which he laid down on the table before me, without deduction. "How's this, my man; you are to deduct for the lime, you know." "Why, Sir Walter," he replied, "my conscience will not let me impose upon you so far—the lime you recommended me to try, and which, but for your suggestion I never would have tried, has produced more than would have purchased the lime half a dozen times over, and I cannot think of making a deduction."'

CUT WORM.

In some years these larvæ are very destructive to the Indian corn, and of all the contrivances for destroying them, which we have seen, that of Park Shee, of Delaware county, in Pennsylvania, is the most simple and the most expeditious. A pair of old wheels from a cart or wagon, are fitted with several projections like the cogs of a spur wheel in a mill, which are so formed as to impress in the earth a hole four inches deep. The smooth track which the wheel makes on the soft ground, induces the worm in its nocturnal wanderings to follow on till it tumbles into the pit. It cannot climb out, and the hot sun destroys it.—*Farmer.*

CHEAP ELEMENTARY AGRICULTURAL PUBLICATIONS RECOMMENDED. AGRICULTURAL BOOKS FOR SCHOOLS.

To the Editor of the Farmers' Register.

Caroline County, Va. May 23d, 1838.

From a communication which I made to you a year or two past,* you will discover that I had been for eighteen years endeavoring to improve my land—naturally poor—by pursuing Col. Taylor's non-grazing and inclosing system, &c. I was never convinced of the impracticability of that system on such lands, until I was led to read your 'Essay on Calcareous Manures.' From your remarks upon my communication in the Farmers' Register, your "five propositions" in the 'Essay' opened my eyes; and from that moment to this, I have never ceased to desire, that every farmer, both rich and poor, should become acquainted with that work. I believe I have induced several to purchase and read it, yet I do not believe there are as many as two in a hundred of our citizens, generally, who are acquainted with the first principles laid down and maintained in that work. I am fully convinced (were they well understood,) that an effort would be made by a great number of farmers, to improve their lands upon a proper principle. I can truly say, that my feelings, upon reading your 'Essay,' were indiscribable; first, deep mortification at having spent 18 or 20 years of my life, with all my youthful zeal in the cause of agriculture, to but little better result, than to be prepared to receive as truths the five propositions laid down in your 'Essay on Calcareous Manures;' and secondly to know how many thousands there were in this, our poor old Virginia, who were going on in the same or greater ignorance than I had been, and who probably would never, in your lifetime or mine, be any wiser for what you had written. As well as I can now remember, I think I had heard of a work written by you on calcareous manures—several years before I was induced to read it; yet the title appeared foreign from any interest I could have, and the work was left by me to those whom I thought interested in *calcareous manures.* This indifference to the work, (as you very well know) must have been owing to *ignorance,* when I tell you (had I then known its importance to every farmer,) that I verily believe I should have at once abandoned the idea of improving my lands altogether, and thereby have avoided heavy expenses, or have acted upon proper principles, and consequently would have reaped the reward of my labors and expenses, either in immediate profits or subsequent permanent improvement.

I have premised thus much by way of introducing a suggestion for your consideration, which is, that you should prepare a small work, embodying the principles contained in your 'Essay on Calcareous Manures,' with such illustrations as may be plain and forcible, also some hints upon the subject of making putrescent manures, and such uses of quicklime as you may have published in the Register, from the work of Mr. Puvis and others, and whatever you may have gathered upon the subject subsequently. Also such hints, in a short but plain manner, as you may think best upon the management of stock of all kinds, &c. &c. Let the work be in a small pamphlet form, in good plain type, and let the price be 25 cents, and have the title 'The Virginia Poorland Farmer's Friend,' or some such name. I believe such a work, with proper arrangements for distribution, might be sold almost as extensively as a common almanac, or Dr. Franklin's 'Poor Richard,' and other small, but important tracts, containing first principles, from which arise results, which never can be told until the final consummation of all things. Your Farmers' Register and other works you have, and are about publishing, will be more particularly adapted to the better educated, and the benefits arising from them must be extended to others through a tardy course of precept and example; but the work I propose commences at the root, and its healthy influence must ascend, and as this is the *course* in our country, it must be soon felt in the topmost branches. I have not made this suggestion upon the spur of the moment. I have had it under consideration for a year or two, and am fully convinced of its great importance. The mind of man seems constantly reaching forward and higher; and much of the usefulness of *many* to their race, is lost by their setting too little value to the inculcation of those things to which *they* have attained; 'tis so in religion, 'tis so in politics, and is it not so in agriculture? Some subjects require technicalities and high sounding words, and cannot be understood by the illiterate reader. Yet I am convinced that more plainness of speech than is frequently used, would be better upon most subjects. In such a work as I have suggested, the simplest and plainest language should be used, (I think your style generally very plain,) so that the common planter can understand; and, by-the-by, most of us are but grown boys, and none of us can be injured by plainness of speech; and a work of this kind should be prized in proportion to its simplicity. I think it was the celebrated John Newton, of Olney, (England,) who said, when he preached a sermon, he fixed his mind or eye upon one of the most illiterate of his congregation, and adapted his language to his understanding; knowing that if he were understood by such a one, the better informed would surely understand him.

I discover the managers of the Richmond, Fredericksburg and Potomac Railroad Company, have with commendable liberality greatly reduced "the freight on marl, lime, and gypsum, for the promotion of *agricultural improvement.*" Yet I have not observed it noticed in the '—— ——' which is more extensively circulated in the country than any other paper. * * * * * "Like priest, like people." How can we expect that interest to be taken in the *real improvement* of the state, so essential to her citizens, when the substantial nourishments of bread and meat are only set before us by yourself; while papers thought a thousand times more important

---

* Published at page 612, Vol. II.—Ed.

than the Farmers' Register, are constantly serving up, and setting before us, the condiments of pepper, salt, and *vinegar*, and making us believe the more of them we swallow, the better will be our digestion; until, in fact, most of us have the dyspepsia so badly, that we shall be compelled to call in some "thumping" doctor, before we shall be able to digest "nature's food."

Your sincere well-wisher,

THOS. B. ANDERSON.

Editorial Remarks.

We fully concur with our correspondent in the opinion that an elementary treatise on agriculture, such as he describes, and desires to be furnished, would be highly valuable to the agricultural community, provided it could be widely circulated and read. But, putting aside the difficulties and labor of the author or compiler, and the expenses of publication, we doubt much, even if such a work were published, whether enough copies could be sold to pay half the printer's bill. It is almost impossible for any author in Virginia to publish and sell a book so as to make the smallest profit. The great publishing houses of the north have acquired a virtual but effective and close monopoly of the publishing business and trade in the southern states; and one of these houses, as, for example, the Harpers of New York, could sell the most worthless new work, (if well chosen for its *demerit*, to make this experiment,) to more purchasers, and at more profit, than any Virginian publisher could do with the most valuable and useful work. Their operations are effected, and objects attained, by combining the *credit system* and the *puffing system*. Hundreds of retail booksellers have credit from some one of the great publishing houses, on the condition of receiving a certain number of copies of every new book published by that house. Thus, an edition of 1000 or more copies of every publication is engaged before it goes to press. The next thing is to get off as many as possible of the dozen copies sent to each retail bookseller; for if this were not done, they could not long continue to buy. To this end, copies of every new work are sent to hundreds of editors of newspapers; and for so small a bribe, these gentlemen rarely refuse to give in return a *puff*, or complimentary notice of the work, which serves to aid the sale. If twelve copies of each new publication are sent for sale to each town, and, on the average, half, only, of the twelve are sold to readers, there will be no loss on the whole publication; and if nine are sold, there will be a sufficient profit. If *all* should sell, then there is a certainty of profit in disposing of another edition.

Without the aid of any such machinery and system, no one can now publish a work, except at loss. If the publisher is not a bookseller, and acquainted with the practical fair operations, and also with the tricks of the trade, and he distributes his copies among many different booksellers in various and widely dispersed places, to be sold on commission, he will scarcely receive enough money to pay for the expenses, losses, trouble, and vexation, incurred. Our own experience on this score has resulted in forming the determination never hereafter to send any publication for sale to booksellers, unless ordered by them as a purchase, and the transactions closed. The particular work of which our correspondent speaks with so much approbation, has been so favorably received by the public, as to leave the author nothing to complain of on that score. Nevertheless, by the first edition, which was *all* sold, he barely paid the expenses of publication—and by the second edition, which was on the cheapest plan, not half the expenses have been paid by the sales. Of the separate edition (600 copies) of Johnstone's 'Treatise on Draining,' recently published at this office, not 20 copies have been sold; and the whole edition has been offered, and in vain, to be sold for the sum actually paid for engraving the wood-cuts which illustrate the work. These statements are enough to show that any Virginian who publishes a book for sale, must count upon receiving his reward (if indeed any is obtained,) in "honor and glory;" but certainly not in profit.

We have long thought of the importance to agricultural improvement, and even to national economy, that might be found in a plan somewhat like that proposed by our correspondent, and which might embrace his proposition entirely. This plan is to furnish for all the common schools, in Virginia, agricultural works to be used for reading lessons. If the legislature would give the first start to this scheme by contracting for such cheap publications to be provided for the boys taught in the primary schools at the expense of the literary fund, (for which general objects $45,000 a year has long been spent, and mostly wasted uselessly,) that demand alone would be so large as to permit the printing of very large editions, and, consequently, the prices of such books might be put so low, that their greater cheapness alone ought to induce their substitution, in all common schools, for the ordinary reading books furnished from the northern publication offices. In this manner, if the publisher were secured against loss, by a state contract for 5000 or 10,000 copies of any one work, it might be sold at less than half the usual prices for northern school-books, and yet give sufficient profit to the publisher. In this manner, if no other benefit were found, there would be the great saving to the literary fund, and to all the parents of young pupils in Virginia, of more than half the price of books designed merely for learning to read; and the books substituted, would be at least as serviceable in that respect, and unobjectionable in every other respect, as school-books. As, therefore, the *patronage* of the state would cost it no money, but on the contrary cause to the treasury a considerable saving of the money now expended for school-books, it might be hoped, even from the legislature of Virginia, that *such patronage* to agricultural improvement would not be withheld. But the saving of money to the treasury, and the consequent hundred-fold saving to individuals, (if these cheap books were adopted in all the common schools,) would be the least of the advantages gained. A very far more important benefit would be the making on young minds impressions which are the most strong and indelible, of matters of useful agricultural instruction. Most of the boys thus instructed, in country schools, would afterwards be engaged in farming; and these early instructions would never be forgotten in after life. Besides—the school-book of the young pupil, when no longer used as such, would be left in his father's house, and would serve perhaps to engage the attention of, and to instruct parents as well as children. And in the far greater number of cases, both of the old and the young, the agricultural instruction thus afforded would be given to those who would otherwise be entirely destitute of every such advantage. The private and national benefits that would *certainly* be derived from having 10,000 or more of such persons, in Virginia, every year thus induced to read agricultural books, are beyond the powers of calculation. And there is no reason why the benefits should be limited to Virginia, as there would be nearly as strong inducements for attaining the same objects in the other southern states.

If such a general plan as this were adopted, the first and the most useful publications would be elementary treatises on different agricultural subjects, suitable to the least informed minds, and to the plainest understanding. But works of higher grade, and exhibiting more of scientific research, might well follow, though on the same cheap plan of publication; and indeed, some agricultural works might well be adopted as text-books in our colleges, even in advance of the future establishment (so much to be desired for agricultural and national improvement,) of professorships of agriculture or agricultural chemistry. Nothing is required but to guaranty to the publisher a sale of so many copies of a book, as to secure him from loss, and the price of those and all other copies may be made at not more than double the cost of so much blank paper.

We should be pleased to hear the opinions of others on this plan of introducing cheap agricultural tracts, and books, generally into common schools. If we were to find it enough supported by such opinions, it might induce the making a direct offer to the legislatures of Virginia, and other neighboring southern states, to furnish such publications in the manner spoken of above; even though that offer to furnish valuable and instructive works at less than half the cost of the common northern school-books, (worthless except merely for practice in reading,) might possibly subject the proposer to the charge of seeking his own gain only, at the public expense.

From the Genesee Farmer.

RUTA BAGA.

The value of this excellent root is rapidly becoming properly appreciated among farmers, and though the feeding out the roots is attended with some trouble, (the only objection we have heard made to them,) the advantages of their culture are so decided, that we may expect few farmers will be willing to forego them. That they can be fed out to any animal, or in any way, without some profit, we do not apprehend; and our experience would go to corroborate the many testimonies we have published from various sources of their excellence, and the ease with which, under ordinarily favorable circumstances, they can be cultivated. In feeding them to animals, the least favorable results have been obtained when given in a raw state to swine. In this respect, however, they have not greatly differed from raw potatoes; either of which fed in this state to pigs seeming to be of little value. The value of potatoes, as every one knows, is nearly or quite doubled by cooking, and some experiments would seem to indicate that a similar result is effected on the turnip by the same means.

Mr. Mayleet, near Montrose, Pa., who last year raised turnips at the rate of 1333 bushels per acre, boiled the roots, and with the addition of some coarse grain provender, fattened his pork upon them. The pork, he says, was excellent.

Mr. Bement of Albany, well known for his successful endeavors to introduce superior animals of different breeds to the farming community, particularly the Berkshire pigs, kept twenty of these hogs, mostly full grown, on six bushels of ruta baga and one bushel of buckwheat bran, a day, for the whole, divided into three meals, two fed raw and one boiled. Fed in this way for three and a half months of last winter, they were found to thrive as well as when fed on four quarts of corn, each, per day; which at the prices of grain at that time, would give a value of 28½ cents per bushel to the ruta baga.

Mr. Mather of Scaghticoke, a farmer of system and enterprise, instituted an experiment in feeding cattle with turnips, to test their value in comparison with other kinds of food, and the result, as communicated to the Cultivator, was as follows:

"I fed two yoke of cattle on turnips for two months—November and December; feed, five bushels a day a yoke. Average gain 115 lbs. a yoke per month. The same cattle were fed through the month of January on potatoes and meal, corn and oats, ground together in equal quantities; feed, two bushels of potatoes, one bushel of meal. Gain 60 lbs. a yoke. Estimate the value of the ruta baga by the price of corn, oats and potatoes, and the respective gains, and it makes the ruta baga worth but a fraction less than 18 cents per bushel."

For feeding or fattening pigs, we should, at present, prefer cooked potatoes to turnips; but when it is remembered, that on an average, three times as many turnips as potatoes can be grown on an acre, the latter, when cooked, may be found the most valuable in the end, and experiments in the case of swine, are needed to settle this point. As food for cattle or sheep, the turnip is superior to the potato; and for making fine beef or mutton, the ruta baga has scarce a rival. We, in this country, are yearly becoming greater imitators of the English, in substituting beef and mutton for pork; a fact we attribute to two causes;—the partial failure of the corn crop, without which it is generally considered impossible to make first rate pork,—and the increased culture of the ruta baga, which has produced beef and mutton of unexceptionable quality.

MARL IN SOUTH CAROLINA.

[The following article will serve, in addition to others before published in this journal, as evidence of the great facilities possessed by South Carolina for using calcareous manures; and also of the deplorable general ignorance of their value and proper application, as well as the failure to avail of this great source of agricultural improvement and national wealth. Could we be permitted to advise and direct a course to be pursued, we doubt not but that every judicious user of marl would thereby make a permanent clear profit of from 20 to 50 per cent. per annum, on his investment; and that the portion of the state marled would be at least doubled, and perhaps quadrupled, in agricultural product. Notwithstanding the great neglect and frequent misapplication of marl, and improper tillage after applying it, its use has already added millions of dollars in agricultural and money value to lower Virginia; and South Carolina, in a few years, might receive as much benefit from a like course—and ten times as much benefit, if a judicious and proper system were adopted and pursued.—Ed. Far. Reg.

[From the Southern Agriculturist.]

Mr. Editor—In your number for the month of May, you insert an article from the Farmer's Register, on the "marl of South Carolina," and its uses as a manure. To excite some interest in the importance of this subject, I beg leave to observe, that marl is found in great abundance in that part of our state which requires it most, and which has a soil peculiarly adapted to it. That marl is found in Barnwell, Colleton, Orangeburg, Charleston, and Sumter districts, I know to be a fact, and believe it to exist in all that section of the state, called the middle and low country. By manuring with it only once in five or six years, and then putting only a shovel of it in each hill,* I have been assured that the land yielded three times as much as ever had been obtained from it, by any other means. One gentleman, who obtained it at his landing on the Ashley river, assured me, that in the imperfect mode of his using it on a part of his field, the produce had been increased 50 per cent. over that of the rest of the same field. But that he afterwards sold the place, and the experiment was at an end. It is peculiarly suited to the flat, sour, poor, sandy soils, of this part of our state, where it is most easily obtained. On the banks of Ashley river, it is so abundant, that it is brought to Charleston, and used for filling up the streets; and yet they who own the fields adjoining, do not employ it as a manure, although required only once in five or six years for that purpose.† It is also found on the Savannah, the Edisto, Cooper river, Santee, and Wateree, but not used any where, that I know of, as a manure.

The fossil shells, and rotten limestone, found on the Santee, and in some other places, in immense quantities, are also of incalculable value as a manure. The marl is different from this, because it is a mixture of clay and sand, with lime. But the lime made from these shells is stronger, and will go farther as a manure, than marl, because of its greater purity and warmth. I believe the lime thus made, is peculiarly suited to the exhausted, cold *clay* lands; and one gentleman in Sumter district, who had used shell lime on his old exhausted lands, told me that it had rendered them more productive than ever they had been—more productive than the best oak and hickory land, which could be found. Who would not rather manure three acres of land, than clear one acre, even in the common troublesome mode of hauling manure? Lime made from these shells, gives but little trouble, compared with other manures, and old land so manured, affords more profit than the best new lands. I believe that lime is not suited to the light *sandy* lands which abound in this part of the country, but the rotten limestone and shells need not be burnt into lime—they may be only scattered unburnt over the soil, and put into each hill, like the marl. There are numerous instances in which the broken shells, old lime, and rotten limestone, have caused an extraordinary increase in the crop. One gentleman told me, that in ploughing an old field, he came upon several old lime-kilns, which had probably been burnt 40 or 50 years before, when indigo was cultivated, and wherever these half-burnt shells were turned up and scattered by the plough, the cotton was vastly finer than in the rest of his field. I did not ask him if he had profited by the discovery, and covered the rest of his field with shells also.

Pray, sir, let me suggest that the Agricultural Society should offer a liberal prize for three successive years, to the best series of experiments with these articles; in which the use of either marl, limestone and shells, or lime, can be proved to be beneficial; and which is best adapted to different soils. Q.

*Which is a very improper mode of application.—Ed. Far. Reg.

† More correctly, *once to last for ever.*

Remarks by the Editor of the Southern Agriculturist.

We commend to the notice of our readers, the remarks of our correspondent Q., on the plentiful supply and value of marl, in our own state, to be had by many, at only the cost of conveyance from its bed, to the point where it is intended to fertilize the soil. If Q. be correct, and we doubt not he is, we have within our own borders, a mine of incalculable wealth; and, with ordinary exertion, we can very soon wipe from our 'scutcheon the reproach, of importing the greater part of our provisions. Our correspondent has, in naming rivers, on the banks of which marl, or fossil shells, &c., abound, omitted the Pee-Dee. We take the liberty of adding that river to the catalogue, lest those living on, or near its banks, may excuse themselves, while they wonder others overlook and do not avail themselves of such valuable, and cheap manure. No observant man ever crossed Port's or Godfrey's ferry over the Pee-Dee, about forty miles above Georgetown, without remarking the mighty mass of fossil shells, &c., yet no man on the Pee-Dee ever (so far as comes within our knowledge) used this manure. The Pee-Dee country, was once, even without the application of this aid, a fine grain country—a country of *prime* bacon memory—a country happier than 'tis now. We say to the people of Pee-dee, in common with those on our other rivers—use and improve the gifts and advantages, of which nature has been so lavish, and you will soon find arguments against moving west.

CAPABILITIES OF SOILS. VEGETABLE PHYSIOLOGY.

Extract from Dr. C. T. Jackson's Geological Survey of part of Maine.

It is evident that plants are not endowed with creative powers, and consequently are unable to produce any new elementary substances; hence the various substances which enter into their composition, must be derived from the air, water or earth. All the saline and earthy matters which they contain are readily traced to their origin in the soil; while the carbon, hydrogen, oxigen and nitrogen that exist in them, are elements which they draw from air, water, and the animal and vegetable substances used as manures.

The atmosphere is composed chiefly of the two gases, nitrogen and oxigen; mixed together in aëriform solution, in the proportion of four-fifths nitrogen, and one-fifth oxigen; besides which gases there is always a certain proportion of carbonic acid gas, amounting to one-ten-thousandth part, and variable proportions of aqueous vapor.

From the carbonic acid gas of the atmosphere, plants derive a large share of their carbon, which is the basis of all vegetable matter. Some of it is also furnished by the fermentation of vegetable and animal substances, which decompose in the soil, and this gas is either decomposed by the leaves of vegetables, or is carried into their roots by aqueous solution and absorption. All fresh growing plants decompose the carbonic acid of the air, take up its carbon, and exhale oxigen gas, and this operation goes on more rapidly while the sun shines upon them. In darkness, plants give out carbonic acid, but the quantity is relatively small, when compared with that which they absorb during the day. So that if a plant is grown under a bell glass, containing air mixed with this gas, the carbonic acid is soon removed, and replaced by pure oxigen.

Thus vegetation is continually removing a substance deleterious to man and all animals, and replacing it by pure vital air—a gas absolutely necessary for their respiration. This beautiful law of nature should never be lost sight of by the farmer, nor should he ever forget the relation which the green woods and fields bear to the healthfulness of the country.

Seed will not germinate, without the joint action of air, water, light and heat. Without these essential conditions, the germ remains, as it were, asleep for an unknown length of time. Seeds, taken from the tombs of ancient Thebes, in Egypt, where they had remained in a dry, dark and sequestered spot for more than three thousand years, were found still to possess their vital properties, and when planted in a botanical garden in London, sprang forth, to flourish in the present age. How long a seed, thus immured in darkness, shut out from all the causes which would produce germination or decay, would remain alive, is wholly unknown; but from the known facts respecting spontaneous rotation of crops and of forest trees, it would seem that the seed remain buried in the soil for enormous lengths of time, before the circumstances necessary for their putting forth arrive. Dead leaves of the forest shut out light, and preclude, in some measure, the influence of the atmosphere, while the sombre foliage hangs over the soil, and serves, by its shade, as an additional cause preventing germination. Thus, I suppose, the seed, buried in the forests, remain dormant until the removal of the shade trees, or the burning of the leaves, gives free access to the causes requisite for germination and growth of the hidden plants; and we consequently perceive a new growth almost invariably follows the removal of the primeval forests. According to Decandole, plants exude from their rootlets certain substances, which have the property of eventually eradicating their own species, while they are not preventive of the growth of other plants; hence he accounts for natural rotation. It is probable, also, that one kind of vegetables may exhaust their proper nutriment, and thus render the soil incapable of supporting their kind, while there are other principles left, suitable for the support of different species. This subject is, however, the most obscure department of vegetable physiology, and one which demands the labor of modern chemists and botanists. Thus much we know, that the conditions above stated are essential requisites to healthy vegetation, and that the soil must furnish certain substances not attainable alone from air and water. When we analyze a plant, we always find a certain quantity of silex, alumina, lime and potash, forming a large proportion of the ashes which is left on burning the plant. All these matters are contained in the soil, in greater or less proportions, and some of them are essential to the growth of the plants. The coating of wheat, rye and barley straw is silex, and gives the necessary strength and hardness to the stalk.

The analysis of the grain of wheat gives a large proportion of the carbonates and phosphate of lime, and we know that this grain only thrives upon a soil containing calcareous matter. It was long ago observed in Massachusetts, and is also seen in certain districts in Maine, that wheat straw grows very well, but the grain does not fill and present a plump and solid appearance, but looks wilted, and is not heavy. This was formerly supposed to be owing to the climate, but on more careful examination it is found to arise from the want of lime in the soil. Many animal manures contain a little of this substance, and it accordingly appears, that where a farm is well manured, wheat will grow well upon it, but a large annual expenditure is required for the purpose. It is observed, that all the grain regions of the country have soils more or less calcareous, and we find, that, by adding lime to the soil, we may produce by art the material wanting; and it appears by the analyses here presented, and by the results of certain experiments which have been made in France, and repeated here, that a very minute proportion of lime is amply sufficient for the purpose. Thus one or two per cent. of carbonate of lime will answer the purpose, and this small quantity costs so little, that any farmer can well afford to apply it to the soil. Indeed, I do not see how he can afford to do otherwise, since he will be a loser, and his more skilful neighbors will be enabled to supply the market, while he will not be able to recover his seed.

It is a great mistake to suppose, that wheat will grow in any soil; for I know, that in many instances, the crop raised the past season, which has certainly been very propitious, did not equal in value the seed sown; and these instances all occurred where the soil was destitute of lime, and was not largely manured.

Unless you wish to waste your labor upon barren and unproductive fields, attend carefully to the nature of your soil, and supply those elements which are wanting, in order to render it fruitful.

From the Farmers' Cabinet.

ON STALL-FEEDING SHEEP.

Mr. Editor:—At a late quarterly meeting of the "Agricultural Society of New Castle county, Delaware," it was requested of the corresponding secretary to elicit from *practical farmers* throughout the state, such information and experience on matters connected with *agriculture*, as might benefit and advance the objects of the society, and when deemed of sufficient interest and importance, to publish the same for the use of its members. Many of them are subscribers to your valuable paper, and most of them interested more or less in sheep. The method Mr. Baynes adopts of making *fat mutton* will, no doubt, be interesting to some of them, and the information he imparts may be relied upon—founded as it is upon *experience*.

Yours, very respectfully,
James W. Thomson.

Wilmington, March, 1838.

CORRESPONDENCE, &c.

Mr. Thomas Baynes—

Dear Sir—I am induced from some practical remarks made by you in a late conversation on the subject of *sheep*, and particularly *sheep for stall-feeding*—to solicit from you still further information on this important branch of grazing—not only for the benefit of our Delaware farmers, (who, in the prospect of a dog-law, for the protection of sheep, from the next legislature, will go much more largely into the business,) but also for the sake of the agricultural interest of the country in general. In all our great markets, *fine mutton* is scarce, and consequently high—it is one of our most *wholesome* meats, and, if properly attended to, one of the most *profitable* the farmer can raise. But unfortunately for agriculture, the great and leading avocation of man—too few of its practical votaries impart their wisdom and experience to others by essays and lectures, who so much need their direction and aid. The experience you acquired in England, and the years of observation you have had in this country as the shepherd of that celebrated feeder of fine mutton, Samuel West, of Delaware county, Pennsylvania, will give great interest to any communications from you on the subject—and as Mr. Barney has given a reputation to Delaware *sheep*, which they richly deserve as—among the finest in the country—practical directions from you, for their treatment, and how they can be best improved and stall-fed, will be thankfully received by those who wish to emulate his example—and profit by his valuable enterprise. Below, I have proposed some queries for you to answer at your leisure, on the interesting subject of *feeding sheep*—without a wish however to confine you to them. Any other information than they ask for, and in your power, I feel assured you will impart, and by so doing, much oblige yours, &c.

James W. Thomson,
Cor. Sec. Agricultural Society.

Wilmington, April 8, 1838.

To James W. Thomson, M. D.

Esteemed Friend:—Thy favor on the subject of sheep was duly received, and I will comply with thy request with pleasure as far as I am able. Samuel West, to whom thee has alluded, a practical farmer near Chester, Pennsylvania, feeds about 100 sheep per year—he purchases them in September, and, if possible, selects a mixed breed of Bakewell and Merino, or Glade sheep. After getting them home, the first thing he does is to wash them in a clear stream of water, to cleanse them from dust or mud which they may have collected in travelling. They are then turned into a pasture pretty well eaten down for a few days, when they are changed to a better one. It is best to change their pasture every week, particularly if the fields are small. They will do pretty well on grass till December, when they should be housed (see directions in answer to thy 4th question.) The cost of sheep for feeding is generally from \$3 to \$5 per head, and will mostly sell for double the first cost when fat.

John B. Baynes, of Naaman's Creek, Delaware, keeps a *breeding stock*, of the fine quality of which thee has some knowledge. He allows thirty ewes to one buck, which is considered about the right number on a farm of one hundred acres—these ewes on an average will have forty lambs, which at 4 months old are worth four dollars per head. But I should recommend the yearlings kept over which would shear seven pounds of wool on the 40 head—equal to 280 lbs. at 40 cents would be,

	\$112,00
The 31 head of old sheep would shear 5 lbs. wool per head, 155 at 40 cents,	62,00
40 lambs, when fat, at 2 years old—\$12 per heap,	480,00
	\$654,00
The food will cost \$1 per head on the 40 yearlings,	40,00
Leaving,	614,00

The farmer's income from his *breeding flock*.

Ewes should be kept well through September and October, and the buck allowed to go with them on the first of October; after this time it is considered best not to keep them too high till towards March, when they should be kept better. Potatoes or turnips should be given them till grass comes. Sheep should be washed about the middle of May, if the weather is clear, shear them ten days after. Some of our farmers may not be prepared to purchase a flock of Bakewell sheep. A profitable business can be done, and at the same time a good stock raised, by purchasing a few good common ewes and a Bakewell buck—it will greatly improve the breed by changing the buck every year and selling off the old ewes. In three years the breed will be very nearly as good as full Bakewell. If two farmers in the same neighborhood could exchange bucks, it would answer as well and be a saving to both parties. I have endeavored to give thee all the information in this, and my answers to thy queries below, I now think of, yet that I have omitted some things I have no doubt, but am willing at any future time to answer any questions and impart any knowledge in my power, to aid thee and the valuable Agricultural Society of the county, whose advancement thee so ardently seeks to further. I remain thy friend,

THOMAS BAYNES.

—

Queries, by James W. Thomson, the Corresponding Secretary of the Agricultural Society of New-Castle County, Delaware,—with answers by Thomas Baynes, of Wilmington, on the management and feeding of sheep.

Question 1.—What breed of sheep do you consider best, and most profitable for the feeding of mutton, in this and the adjoining states, to purchase, principally for the purpose of fattening?

Answer.—Half Bakewell and half Merino. A breed of sheep from the Glade country, State of New-York, answers very well.

Question 2.—What kind of sheep would best combine the fattening qualities, and yield to the farmer the most valuable fleece?

Answer.—*Bakewell*, viz:—Lambs at six months old, worth from four to six dollars, at 14 months, yield six to eight pounds of wool, worth 40 cts. per pound; at 24 months will sell for ten to thirteen dollars; if not sold, will produce from five to six pounds of wool, and have a lamb—continuing thus, till four years old, mostly decreasing in the weight of wool every year; at four, the fleece will not weigh more than four pounds, when they ought to be fed, and never kept older. It is a rule with good farmers, never to have their lambs before first week in March.

Question 3.—What should be the age of sheep to fatten best, and how is a farmer to know their age, and what length of time does it ordinarily take to make mutton sufficiently good for the shambles?

Ans.—From three to five years old. Their age is known by their teeth. At one year old they have two broad teeth in front; at two years old four, and at three years old six, or a full mouth; after this age their teeth begin to shorten.

They require three months to fatten, provided they are in fair order when purchased. Six weeks on grass, and six weeks on grain and hay.

Question 4.—What do you consider the best food for stall-feeding sheep, and how much food should be given to each sheep daily during the fattening process.

Answer.—Corn, oats and potatoes, with hay. It is necessary to be cautious at the commencement; the food should be three-fifths corn, to begin with half a pint to each sheep, daily for five days, increasing gradually to one pint for five days more, and one and a half pints for five days after, when one quart can be given with safety. It is best to give a few potatoes daily, say two bushels to every hundred head.

Question 5.—Is salt essential to sheep at this time?

Answer.—They ought to have it to go to at pleasure.

Question 6.—How many sheep, with advantage to the farmer, and their health, can be fed on a farm of from 100 to 300 acres, and how many can one hand feed and fodder?

Answer.—One hundred is considered a sufficient number for a farm of 200 acres, to be fed in three separate flocks. In England one sheep to every head of cattle is the rule. The labor is very trifling, one hand can attend 100 in one and a half hours—half hour morning, noon and night. *Be punctual to the time of feeding; it is of importance.*

Question 7.—Should fattening sheep be kept housed or suffered to run at large, and whether it is necessary to have any particular form for shelters, racks, or enclosures, for fattening sheep?

Answer.—Every farmer should have at least one sheep-house, to be two stories high; the upper story for hay in part, and to prepare their food in the lower story, open to the south with a yard attached to it twice as large as the house, or to contain twice as much ground as the house stands on. The rack and trough to run around the inside on the lower floor, four feet from the outside wall, to allow a passage; a small trough to be placed at the bottom of the rack, six inches broad and four inches deep, two feet from the floor. The racks must be perpendicular, to prevent the hay seeds getting into the wool, and slope the back of the rack; two feet will be sufficient for the height of the rack from the trough. The hay is given them from the passage over the back of the rack, but the food must be taken inside and carefully placed in the trough, even all along to prevent any one from getting more than his share. It is necessary they have water twice every day. If they go out to water never allow them to be out more than two hours at the time. The pen should be kept well littered.

Question 8.—What are the diseases to which fattening sheep are most liable, and what are the proper remedies?

Answer.—The disease most common is rot or lax—the best remedy known for it is half a pint of equal proportions of soot and salt. When sheep are feeding high they are subject to a disease supposed to be a species of cholic; the best remedy is to bleed at the eye vein, and give an injection composed of lard, molasses, and warm water; an injection is very good when they are too costive, but this never occurs when they have their proportion of potatoes, turnips or sugar-beets.

When sheep get torn with dogs, or by any accident rend the skin, the wound should be well washed with warm milk and water. Stitch up the place and bathe it with tincture of Cayenne pepper or spirits of turpentine.

Sheep are at times subject to foot rot or foul-claw; this can be mostly cured by placing in their path *quick lime* three inches deep, so that the lime will go well up between their hoofs. If this should fail, clean well their feet with a dry cloth, pare off the superfluous hoof, and apply butter of antimony; if it is still unmanageable they had best at once be sold, and then if care is not taken to clean well their pen, &c., the next flock will take it, as it is a contagious disease. Scab is a disease more common in Scotland and north latitudes; it is scarcely known in this country. The best remedy for it, is the oil of tar, placed in the wool on the back; a small quantity is sufficient.

THOS. BAYNES.

[The cautions given in the two following articles are well worth attending to in Virginia, where so much grass-seed is brought annually from the north. We already owe to the purchase of English and northern grass-seeds the introduction of several weeds which will never be got rid of; and it is surprising that we have so long escaped thus introducing the Canada thistle, the worst of all vegetable pests, and which never recedes from any ground on which it has been once permitted to encroach.]

From the Farmers' Cabinet.

CANADA THISTLE.

"Thou shalt not sow thy field with mingled seed."

Great mischief has arisen to our farmers generally, by sowing grass-seeds which were mingled with the seeds of noxious and pernicious weeds, by which means they have been disseminated throughout our country. The Canada thistle was brought from the northern part of the state of New York in timothy seed, and is spreading rapidly in some neighborhoods, to the great dismay of many farmers. I perceive that it has been noticed in your useful Cabinet, but I have not yet seen any thing stated in your columns that can be depended on as a remedy for eradicating it. I hope your correspondents will keep a close watch on this unwelcome intruder, and furnish you with the first successful experiment which results in getting rid of it. A farmer last season who had it among his oats, mowed it with the oats and burnt the whole together. This season it has made its appearance in his wheat, which will be destroyed by it in the part of the field where it has taken root. I hope you will excuse my calling attention to this subject, as it is one of great interest to many

FARMERS.

Bucks Co., June 1, 1838.

From the Farmers' Cabinet.

SOW PURE SEED.

"One year's seeding makes seven year's weeding."

It is very material when about to purchase seed, that we should select a seedsman of the first character, who has made the business his study, and obtained a thorough knowledge of it in its different branches, and not trust ourselves to transient dealers who may have their attention divided between many other articles of merchandise. Such persons may be strictly honest, and yet lack that information which every dealer in the article ought to possess. Always buy the best that is to be had, without regard to a small advance in the price over a common quality, and put plenty on the ground, as I hold it to be no economy to save a few dollars in the purchase of seed, at the risk of having it impure, or a less crop than the land ought to produce. It is also of great importance that we should become good judges of seed ourselves, or we may fill our field with weeds that will require years of trouble, and much expense to get rid of. Many are acquainted with the seeds of the most common weeds found in clover, timothy, orchard grass, &c.; such as wild carrot, daisy, (called underbloom by some persons, and Bensalem clover by others,) wild chamomile, (this also is called underbloom in some districts,) St. Johnswort, wild amaranthus, field sorrel, &c. &c., and as these pests are the common attendants of the grasses, their seeds should be known to us all. To attain this knowledge, I would advise every farmer to collect, when ripe, the seeds of every weed they meet with, fold them carefully in paper, mark and put them away in some secure and convenient place to refer to at any time, until they become so familiar with them that they can detect them easily when mingled with any seed they are about to purchase, and should there be any weeds unknown to any of us on our premises, it would be well to dry specimens of them carefully, and send them in a fold of paper, tied between two pieces of pasteboard, to the office of the Cabinet, where they would be marked by some one of the patrons of that work, and left for the inspection of all. In this way, there could soon be a collection made (to which the writer would contribute all in his power) that would enable the farmer to detect and extirpate many a troublesome weed, which would otherwise overrun his grounds.

To ascertain the true character of plants, they should be taken when they are in bloom, and they may be preserved simply by placing them in some large book with a sufficient weight to press them until they are dry, this will be accomplished in a few days.

FARMER.

From the Southern Agriculturist.

ON THE COTTON CULTURE.

Mr. Editor—In forwarding to you my annual subscription, I shall follow the laudable example of some of your subscribers by furnishing you a few practical remarks for publication. An emigrant from your own state, and the vicinity of your city, formerly engaged in the culture of the long-staple cotton on the main lands, conversant with the modes of culture prevalent there, and now engaged in growing the short cotton, upon the plans adopted throughout the whole western country, my experience has enabled me to detect some of the errors formerly practised by myself, and my neighbors in Carolina. My attention has been called to this subject by the perusal of an article in one of your late numbers, signed "An Observer," giving an account of the crop of E. Frost, Esq., in St. Andrew's Parish. Mr. Frost, it appears, planted, according to the low-country system, four acres of cotton to the hand, and each hand made 4,000 pounds seed cotton. This, the writer considers an extraordinary production —and for that region of country, so it is. It may safely be predicted that it will not soon be equalled by Mr. Frost, or any of his neighbors. With hands till lately accustomed to the same manner of working, I planted last year ten acres of cotton and ten of corn, to the hand. I never had a cleaner crop, and though the season was excessively wet, my negroes never performed their tasks with greater ease. The cotton crop, seriously injured by the worm, yielded 800 lbs. to the acre, and 8,000 lbs. to the hand. Mr. Frost's land exceeded mine in productiveness, yet my crop doubled his. His is considered so extraordinary, that it is held up as an argument against emigration—mine, was an ordinary crop, nearly doubled by many of my neighbors. But the question to be solved, is, how is the difference in the results obtained?

It is unquestionably true, that the soil and climate of the west, is better adapted to the growth of cotton—that here, a plant of the same size, and on a soil of equal strength, will send forth and retain a greater number of pods, than upon the sea-board. It is equally true, that the grass will grow as rapidly and as plentifully in the one place, as in the other. The difference in the soil and climate has not, however, as much influence, as is generally imagined, by residents on the sea-board. Would they adopt the same management, pursue the same modes of culture, which, somewhat modified, they unquestionably can, there can be no doubt, that though they could not obtain the success of the western planter, yet they would make some approximation toward it.

What then is this management and mode of culture?

1. The overseers are practical men and well paid for their services. Those most readily, as well as most generally employed, are such, as in addition to the general qualifications of integrity, industry and sobriety, have once tilled with their own hands their own soil, or have *cropped it* with others. They know what they have done themselves, and consequently what to exact of others; what the implements of labor should be, and most generally how to make and to mend them. It is with them common law, and almost universal custom, that they are to rise with the negroes, remain with them while they are in the field, and personally direct and inspect all that is done. They fear not labor, rain, or sunshine. To be seen attending to their business by negroes or employers, on *horse-back*, with *glove on hand* and *umbrella over head*, they would feel as a personal degradation and justifiable cause for "notice to quit." In general they will have no driver under them, by his example to teach others how to be drones, to do nothing himself, and to expect or exact little of others, and to divide responsibilities with them. In quickness of step, facilities, and despatch of business, their example, and theirs only is to be imitated. When the hands are necessarily divided, so that all cannot be under their direct inspection, they select one in each gang to be the foreman, and such a one, as will take a pride in being a leader, and will faithfully report all defaulters.

2. Negroes are well fed and clothed. They have their weekly allowance each, of three hundred pounds of bacon, or its equivalent, and as much hominy or corn flour, as they can consume, ground at the mills, delivered to them. When potatoes and peas are in season, they are permitted to use all they may want.

3. The horses, mules, &c., used on the plantations are of good quality, and well used. When purchased they must be recommended by their capacity for hard labor, and for the quickness of their step. If these are obtained, expense is a secondary consideration. The judicious planter does not act as though he thought that an animal good for nothing else fit for the plough. He will not use his broken-down carriage horses, mules worn out by harsh treatment, nor "old field tackies," which cost the catching of them, and waste the time of his negroes in following their snail-like steps. The description of horses and mules used under the charge of an overseer, such as has been described, ensures in a land of plenty, the greatest care and the best treatment.

4. But it is by the use of the plough that so much is achieved. By it, the beds are prepared for planting, the trenches or drills made, and the seed covered. By it, the most part of the grass is destroyed and the plant furnished with the requisite earth for its support and sustenance. By it the use of the hoe in a great measure may be dispensed with, and when used it will require comparatively but a small portion of physical strength.

It does appear to seem strange that the hoe-culture should ever have prevailed to the extent that it has on the sea-board, and more strange, that it should continue in this utilitarian and labor-saving age. Is it objected that the lands are low and intersected by drains and canals? There is indeed some force in this objection, but not enough to exclude the use of the plough. The lands in many places might be cleared and drained with a reference to its use. It may be safely affirmed, that there are few plantations, where the labor-saving machine could not be used, to the reduction at least of one-third of the manual labor.

It may interest some of your readers who groan under the pressure of their crops of eight acres of corn and cotton to the hand, and whose fears are alarmed lest the grass should overrun them, to learn how, by the use of the plough, twenty acres to the hand can be planted and the same crop secured. I will, therefore, give you in detail the arrangement of the crop on our plantation last year. There were, besides the regular crop, 75 acres of oats, potatoes, and slips, enough for the use of the plantation, and about 15 acres of wheat. The plantation worked 30 hands—15 at the plough, the rest with the hoe. In March, 300 acres were planted with corn, on land previously well ploughed and checked. In the first week of April, 300 acres of cotton were planted. The land was prepared by throwing together, with a turning-plough in the alleys of old cotton-fields, four furrows. Thus bedded, the drills were opened with a small scutter, or bull-tongue plough, in which the seed was sown; they were covered by a board fastened on the plough-stock, in the place of the mould. The drilling, planting and covering, occupied four days and a half. There was an excellent stand, and no replanting necessary. The ploughs and hoes then went into the corn-field. These were well ploughed and hoed by the time the cotton was out of the ground and required work. The cotton was four times ploughed, and as often hoed, and when laid by in July, a hat would have held all the grass that could have been found. The corn was twice more ploughed, and once hoed. The grass was constantly kept down by the ploughs. The daily task of a hoer was 100 rows of cotton 100 yards long. The first and second hoeings, when the cotton had to be chopped out and reduced to a stand, proved good, though not severe tasks; the other hoeings were light, and the workers were often out of the field by 12 o'clock. The crop was well worked, and with ease, by low-country hands, who would think it the worst calamity that could befall them, to be compelled to return to the place of their nativity. The mules and horses were in as good, if not better condition, than when the ploughing commenced.

In this exhibition which I have given you, of the management and mode of culture adopted by western planters, and of the working of a single crop, it appears to me that a stronger argument can be found against emigration from your shores, than can be deduced from the plans of Mr. Frost, or the suggestions of "An Observer." C.

Houston County, Ga., April, 1, 1837.

From the Genesee Farmer.

EFFECT OF NATURAL CAUSES ON THE AGRICULTURE OF ENGLAND AND THE [NORTHERN] UNITED STATES.

The question has been, not unfrequently, asked, how far are farmers in the United States justified in following the example and practices of British agriculturists? This question assumes an importance it would not otherwise possess, were it not a fact, that we look with great interest to the results of agriculture in that country; that most of our standard agricultural works are from that side of the Atlantic; that the wealth and resources of England are such as to render that island a great theatre of experiments; and, that the arts and the sciences which can be brought to bear on the cultivation of the soil, are far more extensively diffused and better understood there than here. Having the same Anglo-Saxon descent, the influence of England is felt in every department of our social condition; in our religion, literature and law; and perhaps is as potent as any where, in the usages and practices that belong to the cultivation of the earth. In our implements used on the farm, we copy from English models; in improving our breeds of horses, sheep, and cattle, we look to stock imported from England; in our horticulture and floriculture we follow the example of English planters and gardeners; and in our farming operations, in culture, and in selection of grains, the influence of that country is paramount. It is necessary then to inquire how far we may safely follow such an example, and in what respects we ought to deviate, or when it becomes necessary to do so.

To determine this question correctly, it is necessary to take into consideration the position of the two countries, so far as regards climate, soil, and population, and their influence on plants, and the prices of labor. In general, it may be laid down as a correct position, that the difference between the soils of the two countries is not of a kind to render any difference of culture important. The analysis of soils effected by Sir Humphrey Davy; the geological structure of the British Islands; and the extensive and minute reports made on the soils in the agricultural surveys of the several counties, show that there is no essential difference between the composition of the greater part of the British soils and ours. Peat and bog soil, alone, is found more extensively diffused than with us; but this has but little influence on the general progress or course of agriculture.

Population, by justifying or rather compelling English farmers to adopt peculiar systems of farming, may be said to create a wider difference between the agriculture of the two countries than any arising from the soil. Owing to what may be termed an immense surplus population, the price of labor is reduced to the lowest possible rate at which bare subsistence can be procured, and in consequence, many methods of farming are there adopted, which could not, at the prices of labor and products, be otherwise than ruinous here. For instance, weeding wheat and other kinds of grain is a very common practice there, and multitudes of women and children earn their bread for a considerable part of the season in this manner. It is clear that this operation cannot be introduced among our farmers, though its effects in keeping the soil clean, and in increasing the amount of the crop, must be evident. Another consequence too of the cheapness of labor, is, that many operations are performed by hand, and at a far greater expense of time, than are accomplished by the aid of implements here, and in one-fourth of the time. This no one can doubt who is in the habit of employing on the same farm English and American laborers; and of which an illustration is given by Mr. Bement, in his history of the culture of the ruta baga, in the Cultivator for January, 1838.

But it is to the climate that the principal points of difference in the agriculture of the two countries must be traced; and this is the thing that should be kept most distinctly in view, when comparisons between English agriculture and our own are instituted. England, though in the latitude of Quebec, has a milder climate than our middle states, and this fact should not be lost sight of in adapting the agriculture of that country to this. In the United States,—we speak particularly now of the northern and middle states—as it is these that are more influenced by English agriculture than the south,—the summers are much hotter and the winters much colder than in England; hence some plants, that require a great degree of heat, will succeed better here than there; while many plants will bear the winters of England in the open air, that perish when exposed without protection to the intense cold of our winter months. A great number of thermometrical observations show that the average temperature of the three months of January, February, and March, in England, is about 37°, 42°, and 47°, and that of the three months of June, July, and August, to be about 63°, 66°, and 65°. The average difference between the highest and the lowest temperature per month will not exceed more than six or eighth degrees, those sudden and extreme changes to which our climate is subject being unknown there. In the valley of the Genesee, near the Ontario, the average for the three winter months gives about 24°, 26°, and 36°, and the three summer months an average of 71°, 73°, and 72°. The mean average of several years is 49°, and the range of the thermometer about 100°. In this country we have changes of from 30° to 40° in twenty-four hours; there the greatest rarely exceeds six or eight. The thermometer range in the United States is more than 120°,—in England not more than 45°. There the thermometer rarely descends but a few degrees below the freezing point; here it is below for weeks or months. Indeed it is probable that, in the colder parts of the United States, the thermometer falls below 0°, as often as in England it does below 32°.

This statement will show that there must be a material difference between the agricultural operations proper to two countries so situated, so far as those operations can be affected by climate. To give one instance;—Indian corn it is ascertained cannot be grown in any country where the thermometer for more than one month is not above 70°, and that in a temperature of 75° or 80° it arrives at its greatest perfection. This is the reason why, notwithstanding all the efforts made to introduce corn into Great Britain, it has proved a complete failure. It is not killed with the frost there as here, but the degree of heat will not bring it to maturity during the summer months. Cobbett was confident he should succeed, and did grow some tolerable crops of early Canadian, but like some trees which flourish and mature their seeds here, but will not ripen in England, the corn would not in all cases mature so as to vegetate, and, spite of his boastings, he was compelled to abandon the culture. On the contrary, wheat is a crop that requires a lower temperature than maize, and is not adapted to a hot dry climate. Great Britain is therefore one of the best wheat countries on the globe, and perhaps produces, in proportion to the land in tillage, a greater amount than any other. The low temperature and moist climate of England is found to agree with this plant perfectly. Scotland is too cold; but no part of the Island is too hot, as is the case with no inconsiderable portion of our southern states.

In another important respect the climate of the two countries exercises a decided influence, and that is the planting and growth of timber or ornamental trees. Mr. Prince of the Linnean Garden at Flushing, remarks on the acclimation of trees, "that the *deciduous* trees of Portugal, Italy, and Spain; and of South Carolina, Georgia, and Louisiana, will endure the winters of New York, when the *evergreens* from the same places perish if unprotected. Though in England where the winters are moderate these survive and flourish, while from the want of heat in their summers, many of the deciduous trees do not ripen their wood sufficiently to support their climate in winter; whereas beneath the powerful sun of our country, the wood becomes so well matured, that it, in many instances, resists the rigor of our winters uninjured. A consideration of these circumstances, and effects of climate, may greatly aid those concerned in the acclimation of trees." In the work on Planting published in London, speaking of American forest trees, the following remarks are made. "But the oaks of North America, claim the deepest attention of the ornamental planter. Ranging through many degrees of latitude, and growing at different elevations, consequently under much variety of climate, some of them are hardy with us, some tender, but all abhorrent of wet or clayey soils. Deprived of the cloudless sun, and high temperature of an American summer and autumn, they cannot ripen their shoots sufficiently to be frost proof except in warm places and soils of a light nature."

As an instance of the effect of climate on trees we may mention the *Platanus occidentalis*, the common sycamore, or buttonwood, of our forest; a tree which every one knows fringes the margin of most of our streams, and rears its majestic trunks in the rich alluvion of all parts of our country, one of the hardiest and most rapid growing forest trees of the northern states; yet of this tree, the work on planting to which we have referred says, "that it has proved incompetent to withstand the spring frosts, sunless summers, and clouded autumns of England. About twenty years ago a great proportion of the individuals in England, without respect to age or bulk, were killed outright by a spring frost. Since then we have seen them repeatedly injured, and, when half recovered by the operation of a summer of more than average warmth, again replunged into the same state of debility."

To this difference in climate must be attributed the difficulty we have found in the United States of growing hedges from such shrubs or trees as are used in England for this purpose. From witnessing their excellent effect, and beautiful appearance there, it was perfectly natural that we should adopt the same plants for the same purpose here, but after the repeated and persevering efforts of fifty years, it may be questioned whether there are five miles of tolerable hedge from imported varieties of thorn or holly plants, in the United States. The difference between the moist, temperate, and equable climate of England, and the hot, dry, variable climate of this country, seems to have been overlooked; when a recollection of this fact would have convinced any one acquainted with the physiology of plants, that our seasons must be fatal to English hedges. Whether there are any of our native plants that will supply this desideratum, remains to be seen.

Not immediately connected with agriculture, but still closely associated with its prosperity, is the effect of climate on roads. In England all the principal roads are Macadamized or covered with a thin layer of finely broken stone, that uniting by its own angles forms a pavement of rock impervious to water and smooth as a floor. Vast sums of money and labor have been spent in this country in attempting to give some of our principal roads such a surface, but mostly without success. The frosts of our winters penetrate below any coat of metal that can be applied, and the lifting and heaving thus produced will break up and destroy the pavement annually. There can be no doubt that more labor and stone broken, has been applied on the Seneca turnpike between Utica and Canandaigua, than on any similar road in England; yet while one is as smooth as if composed of solid rock, the other for some months in the year is almost impassable. This is owing to the greater intensity of our frost; and in constructing our roads, by overlooking this difference of climate, or not properly guarding against it by deep and effective draining, we have followed a system not adapted to our country. Against this additional difficulty our lines of rail road must contend, and any system of construction that shall place them beyond the action of frost, will be a national benefit.

The worst effect which our variable climate and intense cold has on our agriculture, when compared with that of England, is its influence on our wheat crop. Such a thing as winter killed wheat is scarcely known in that country; while in many parts of this, especially where clay predominates, wheat in all seasons is more or less liable to injury, and in some years has more than two-thirds perished. The heaving out of the roots of wheat and clover plants by the expansion of frost, and which is here the most fatal in the spring of the year when it thaws the surface by day and freezes it by night, is something which agriculturists in that country are rarely called to guard against, and which of course never enters into their calculations in the preparation of their soil. Here it is advisable in all cases to guard against the evil, by such a system of ploughing and manuring as shall most effectually obviate the danger arising from this source.

In reading or adopting the modes of English farmers in the preparation and application of manure, the influence of climate should not be forgotten. If any thing has been established by agricultural chemistry, it is that all manure loses in value exactly in proportion as the fermentation and decomposition goes on in the open air, by which most of the volatile and finer parts of the manure is lost to plants. In a high temperature, such as our summers possess, yard or stable manure will ferment rapidly, and if left as it generally is, exposed to the rain and sun, its value and efficiency is much lessened. If piled in large masses, as is practised by some farmers, and then allowed to stand through the summer, a custom followed to some extent in England, it must be remembered that fermentation and decomposition go on here with a rapidity unknown there, a fact depending on the greater heat of our summers, and hence the more necessity of guarding against the loss of the fertilizing gases thus liberated. The proper place for the decomposition of manure is beneath the surface of the earth; but where it is desirable, as it sometimes may be, to keep it over the summer for fall application, the manure should be piled in layers alternating with earth, (and if this is partially combined with lime so much the better,) which will absorb the volatile salts and parts thrown off by the decomposition and fermentation which in our climate must take place, and the quantity and quality of the manure will be greatly increased, over what it would be if left to ferment in the yard, or heaped, but uncovered with earth.

It appears then, that in things relating to the soil alone, its preparation or amelioration, the application of animal or mineral manures, or the artificial arrangement of crops, American farmers may with safety copy the example of British farmers, and derive important advantages from the perusal of English works on agriculture. So they in general may, in all things relating to the preservation of crops from insects or diseases, such as the grub, cut-worm, blight, mildew, wheat-worm, &c., as these are common to both countries, and the balance of experience is altogether in favor of Europe. In every thing relating to wheat they are entitled to a hearing above all other men; as in no country is the culture of that valuable grain carried on so successfully; and this is owing in a great measure to the skill and science that has been brought to bear on the production of that crop. In raising cattle, and the common and improved breeds of middling fine wooled sheep, English farmers are exceeded by none, and on all these topics they may be considered as qualified to instruct us. Fine-wooled sheep, however, notwithstanding the pains taken with them have never succeeded in England. The imported Merinoes from Spain and Saxony have deteriorated and wasted away; and their place with the English farmer is supplied by the hardier and heavier Leicester and South Down. The immense quantities of fine wools used in the English factories, are imported from Germany, France, and Spain; and hence in the management and growth of the fine-wooled breeds of sheep, we have little to learn from them. There is no doubt that the production of fine wool is at the present moment far better understood in the northern states than in England, and there are more Saxon and Merino sheep in Vermont and New Hampshire, than in the three kingdoms.

But it is mainly on those points of agriculture where cheapness of labor, and the influence of climate can be brought to bear, that we find British agriculture to cease from being suitable models for us, and are thrown on our own resources of observation and comparison. Because corn cannot be grown in England is no reason why the farmers of the United States should not plant; and on the other hand, because the whin and the holly make a durable and beautiful fence in England, it furnishes no conclusive proof that such results would ensue in our country. English farmers use little or no precaution against the winter killing of wheat, or the destruction of roads by frost; but here such precautions are essentially necessary, and based on reasons, respecting which the English farmer knows nothing from experience, and therefore must be illy qualified to instruct.

A comparison of English experience in farming, with our, in some respects, ruder methods of proceeding must be always advantageous, as suggesting hints for improvement, and enabling us to correct errors into which, for want of such experience, we are prone to fall. But to infer that any course would, as a whole, be successful here, simply because it has proved so there, would imply an ignorance of the causes that are operating to produce great differences in the methods of culture there and here, which should not exist; causes which may be traced to the powerful, but too frequently overlooked operations of temperature and climate, and which are therefore ever acting and permanent.

From the Journal of Commerce.

CLIMATE AND PRODUCTS OF EAST FLORIDA.

St. Augustine, April 17th, 1838.

MR. WM. VIBER,

Sir—Gen. Peter Sken Smith has handed me yours of the 3d of March, making inquiries respecting the climate and productions of East Florida. He states that his various engagements will make it inconvenient for him to answer you. I have consented to do it, and the more readily as I can trust to the publicity which you propose to give the facts communicated, meeting the eyes of those who have made similar inquiries of me. I would thank you to procure the publication of the answer in the Northampton (Mass.) paper.

I will adopt the course suggested by you; taking the liberty to vary some of your questions, and to add some put by others: For the satisfaction of those interested in silk growing, I send you the enclosed impressions of leaves: one of the Chinese mulberry, one of the native mulberry, and one of the Italian; all taken on the 4th of April inst. and which, if you please, you can give with this article, by a wood cut, at a trifling expense.

Is St. Augustine a healthy summer, as well as winter, residence for northern people? It is pronounced not only perfectly healthy, but agreeable, by many northern people, who have spent the summer here, and by many northern families who have settled here permanently.

What is the general effect of the climate of St. Augustine on northern invalids? Persons laboring under pulmonary, asthmatic, bronchitis, or dyspeptic complaints, may find a cure here if they come in the early stages of those diseases. In many cases it would be necessary to remain through the summer, and in some a permanent residence would be indispensable to a perfect cure.

Is Florida as a country healthy? Many places in the interior are unhealthy in summer.

What extent of country can be found on the coast where northern families could reside during the summer free from fear of southern diseases? The country between the ocean and the St. John's river, embracing a district of one hundred miles long and twenty wide, is generally healthy, and so are many points on the Gulf coast.

What is the quality of the soil? The pine barren is somewhat similar to the land between Albany and Schenectady. The hammock is low land covered with live oak and other timber. When drained and cleared it makes the finest sugar land. The shell lands, lying on and near the margin of salt water rivers, are those soils where oyster shells have been deposited, which gradually mix with and enrich the soil. These lands produce corn and cotton. Some of them have been cultivated since the settlement of the country in 1565 without manure—and the best portions of them will produce from thirty to forty bushels of corn to the acre. Two crops of Cuba corn can be raised in a year. Since the war commenced the average price of corn has been $1 50 per bushel.

What is the relative profit of cotton compared with corn crop? About threefold from Sea Island, which grows well in every part of Florida.

Is there any particular skill required to raise cotton and prepare it for market? None that cannot be readily acquired by any intelligent man.

Is cotton growing carried on wholly by negroes? It is often raised by white labor, and plantations vary in size, as at the north, from a few acres up to a thousand.

What is the relative value of sugar crops compared with corn, and can it be raised to profit in small quantities? Good hammock land well reclaimed ought to yield a clear profit to each hand, at present prices of sugar, $400, and there is no reason why it should not be cultivated by white labor in small lots. Indeed it has been common for the small planters of this country to raise their own syrup and sugar. Live oak answers well as a substitute for iron rollers to grind cane. The cost of a wooden sugar mill is about the same as that of a cider mill. Sugar produced by white labor will, I presume, command a ready market and higher prices from those abolitionists who will consume nothing raised by slave labor.

Are rice, tobacco, and indigo, raised in Florida? Rice can be profitably raised only where the rise of the tide flows back the fresh water rivers so as to submerge the land. East Florida cannot therefore be called a rice country. Havana tobacco has been, and can be raised here, to great profit, and is a sure crop. Indigo was once extensively cultivated, but at the present prices would not pay for expenses.

Is the country well adapted to oranges? Few places in the world where the orange tree has grown to so great perfection, and none where the fruit is better. The frost of 1835 destroyed the trees, many of which had stood nearly if not quite one hundred years. Extensive groves have been set out, and they begin again to bear. A few were produced last year, and there are some now in blossom. The trouble of raising orange trees here is about the same as raising apple trees at the north. The average produce of a tree ten years old would be five hundred, of one twenty years old, a thousand oranges. Many trees produce annually twenty-five dollars. Light sandy soil is required for oranges; and as the tree advances, shell or manure can be added to hasten the growth of the tree if desired.

Are the wild oranges (said to abound in the wood) the same as the cultivated, and are there in fact large groves of them? They are as large as the cultivated oranges, many of them palatable, though generally acid or bitter. They are found in such quantities that ship loads might be gathered from a few acres of land.

Is the mulberry a native of the country? Has the Chinese mulberry been tried there, and if so, how does it succeed? The native mulberry abounds in the woods, but the Chinese can be produced so easily and abundantly, that it must be preferred to any other kind tried in this country for silk worms; and besides it puts forth leaves more than a month earlier than any other mulberry here.

Will Florida become a silk growing country? I believe it will. A few worms have been raised yearly for the last few years. Several thousands are now on hand. They appear to do well, and I believe would thrive in the open air, if protected from the winds. Those who attend them say that they pass through the various stages of their growth in fine health, and are great eaters. Some hatched on the 27th of February, completed their cocoons on the 9th inst. My ignorance of silk-raising admonishes me to give you facts rather than my opinions. So far as mulberry leaves are connected with silk business, there is perhaps no place where they can be raised in so great quantities so cheaply as here. The Chinese mulberry will grow from a slip over ten feet in one year. Mr. Ephraim Hart, of Utica, can testify to this fact, who made the experiment last year. They grow well on the pine barrens. I have made the experiment with white labor, and find that slips can be put out after the ground is prepared, for thirty-seven and a half cents per thousand, including cutting of the slips. Suitable lands can be purchased for $3 per acre. If twenty thousand dollars (the sum said to be laid out by the Genesee company for mulberry alone) were expended in this country in purchasing land and putting out the Chinese mulberry, it would be sufficient to purchase four thousand acres, and plant a slip on every square yard. The Chinese mulberry will grow as much here in one year as it will in western New York in three; and the difference in the production of leaves is still greater, as here successive crops of leaves may be picked from the same tree. Minorcan children would offer in hundreds, if required, to collect leaves, or perform such service as would be necessary in a silk establishment.

What is the price asked for lands suitable for corn, cotton and oranges, in the vicinity of Augustine? Good farms can be bought for from four to ten dollars per acre. The abandonment of all the plantations from fear of the Indians has been the cause of the present low prices. Plantations on the North river, (which is navigable from eight to twelve miles from this city) can be bought for from four to seven dollars per acre, the soil well calculated for cotton or corn, and as good as can be desired for oranges. These plantations contained fine orange groves before the frost of 1835.

What other fruits can be raised to profit about St. Augustine? Figs, peaches, pomegranates, plums and citrons thrive well here, and can be raised to any extent.

Are potatoes easily raised there? The sweet potato is much cultivated and is a sure and very profitable crop. Its quality is superior to that of the potato raised farther north. The Irish or common potato grows well here. Two crops can be raised in a year. The plantings of February will come in for use the last of this month. Small parcels are already offered in market.

What is the state of society in St. Augustine? A. The majority of the inhabitants are descendants of emigrants from Minorca, Smyrna, Port Mahon, and other places on the Mediterranean, who settled in this country during the British occupancy. They are a peaceable, inoffensive people. The women are remarkable for neatness and industry. They are Catholic in their religion—observing the Sabbath in the manner of the Spaniards, but otherwise orderly and obliging. Of the Americans, there are many intelligent and enterprising men with cultivated families. They are of the Episcopalian, Presbyterian, Baptist, and Methodist faiths. The two former sects have each a settled minister and a good house of worship. The Baptists and Methodists have neither. The Catholics have a church and schools. A college has recently been established in the city.

Is East Florida capable of supporting a large population, and what are the prospects of a speedy settlement? A. The proportion of good land suited to the growth of cotton is greater in East Florida, than in South Carolina, and as great as in Georgia. There are very large tracts of sugar lands, equal to those of Cuba. Lands too light for either cotton or sugar, are well suited to the orange and other fruits, the raising of which will give profitable employ to a large population. From the peculiar advantages presented by the soil and climate of Florida to emigrants, the country must settle with a rapidity equal to Michigan or Wisconsin, and in a few years East Florida will become a state, and will furnish, at no distant day, a supply of sugar and fruits to the United States. The whole country is interspersed with navigable lakes and rivers, and there is no region of the United States, where good roads can be made at so small an expense, except it be the prairie country of Illinois.

In answer to several questions relative to families of small property being able to obtain as comfortable a living here as in the north, they can by referring to the facts before stated, decide for themselves. Much will depend on industry and economy in this as in every other country. I will, however, remark, that I have nowhere seen poor people live so comfortably with so little labor as some of them do here. This is owing, in a great measure, to the absence of winter, the abundance of fish and oysters, and the ease and cheapness with which vegetables are raised. Northern men intending to settle in this country, should know that since the war commenced no lumber has been cut in East Florida, or bricks made. All building materials for the present must be obtained from the north. Should you desire further information in relation to Florida, address me at Buffalo, during the summer, and I will answer you with pleasure. Yours, &c.

SAML. WILKESON.

[The foregoing article was accompanied by the representations (referred to above) of mulberry leaves of the natural size. Measuring these by their longest *straight* lines, the sizes are as follow:

Chinese mulberry *(Morus multicaulis)* length		$8\frac{1}{2}$ in.
Native or Red mulberry *(Morus rubra)*		$3\frac{3}{4}$ in.
Italian (White) mulberry,		$1\frac{3}{4}$ in.

If the design of this exhibition was to show the general comparative sizes of the leaves of the several kinds, it is delusive; and so are most other statements of comparative sizes. The sizes of leaves are very different at different times, and situations, not only of the same kind of mulberry, but even upon the same plant. Young trees, and in the most succulent state, and during the most forced and rapid growth, have much longer leaves than afterwards. The leaves of the Chinese mulberry are certainly larger than those of other kinds; but few of us, however, have ever seen any of that kind, except in very young plants, rapidly forced by rich soil and careful culture—and therefore, the leaves are much longer than will be found in after times, and with proper and economical culture. We have seen leaves of young and succulent trees of the native mulberry, grown in the woods, as large as a breakfast-plate—and measured one which was more than twelve inches on its longest line. Yet the same individual would afterwards probably bear leaves not half so long.—ED. FAR. REG.

IMPORTANT TO FARMERS.

A machine has been invented by Milton Dayton, of East Hampton, Long Island, by which he thrashes his own grain, at the rate of fifteen bushels per hour—grinds it at the rate of two bushels per hour—saws his own timber at the rate of one foot per minute, and dresses his flax in proportion. The machine is carried by two-horse power. The expense does not exceed three hundred dollars, and a mere trifle will keep it in repair. It will be of great advantage to farmers, and especially in neighborhoods denied the advantages of water-power.—*Farmers' Cabinet.*

From the Southern Agriculturist.

ON GRASSES.

Athens, Ga., March 6, 1837.

Dr. James Davis:

Dear Sir—I have to day read, with great pleasure, your article, in the Southern Agriculturist, "On Grasses for South Carolina;"* because, in it, you speak, I think, in proper terms of the Gama-grass. I began my experiments with it, about the same time with yourself, and very soon became convinced of its exceeding great value. My attention was directed to it from the conviction, that we must look among our native grasses, if we wished to procure plentiful supplies of forage for our cattle.

You remark, that the only objection you know of to this grass, or rather the only difficulty attending its culture, is the difficulty and tardiness of propagating it. Allow me to suggest, most respectfully, that your "objection" is very easily obviated. All you say of the difficulty of collecting the seed, I have found to be exactly true. I attempt not, therefore, to collect seed; but let it drop; and dig over the surface of the soil in the fall to cover the seed where it may happen to lie. In the spring following I find it comes up thick; and taking advantage of a moist day, I take up the young plants, and set them out where I want them to remain. They are so tenacious of life as to occasion no loss in transplanting.

I have tried another mode of propagation with equal success. I take up the old bunches early in the spring, and divide them; and set them out again (just as shallots are divided and set out); and I have found that they grow without any difficulty. I have taken up a single bunch, one year old, that when divided gave me *seventy* plants.

In either of these modes, if diligently pursued, there is really no difficulty of propagation to complain of; when we consider the very great value of the thing when it is done: and its very great durability; as you may easily prove by figures.

An acre set 2 by 2 feet, will contain about 11,000 plants. Suppose a bunch one year old, when taken up and divided, gives only 30, instead of seventy offsets. To plant an acre the second year, you have to begin with 366 plants. Taking both modes together; that is, dividing the roots, and taking up what comes up from the seed, and half that number of plants would be enough to begin with. But suppose it required double the number; I think tardiness of propagation should not be an "objection," especially as an acre once planted will last a man his lifetime, most probably.

As to duration, the only information I have is derived from a gentleman of Alabama, who states that *nineteen* years ago he enclosed a lot of it, as he found it growing on his land; and that now it is better, and yields a greater crop than when he enclosed it.

I have ascertained satisfactorily, that *thirty thousand* pounds of green grass to the acre, is a moderate crop. Carefully dried, the loss is as 17 to 5: that is, 17 pounds of green grass will give 5 pounds of well-cured hay.

No man who has the slightest regard for the independence of his own state, or for his own comfort, should lose a moment's time in getting a few acres well set with grass. For hay, or green food, or soiling, both in ease of cultivation and in value, it is as far above the clover and timothy of the north, as our cotton is above their onion crops; and the only thing that can prevent its universal cultivation here, will be our over propitious climate: adding another to the many facts already existing, going to establish the truth, that where nature is over bountiful man is always a spoiled child.

If the hints I have given shall be of any service to you, I shall be particularly gratified.

Very respectfully,

James Camak.

Columbia, S. C. March 11, 1837.

Dear Sir—The testimony you add in your esteemed favor of the 6th inst., in favor of the culture of the Gama-grass; and the suggestions you offer for surmounting the difficulty of its propagation, are particularly gratifying. Fully persuaded as I am of the vast importance to this state, and, I have no doubt, to Georgia likewise, of cultivating the grasses in conjunction with the cultivation of our favored staples, I cannot but hail, as a happy presage, every effort that is attempted in furtherance of that object. And as the gama-grass must assuredly hold out a fair promise of a rich reward, I think every intelligent patriot discharges one substantial duty, when he encourages the extended cultivation of it.

Your suggestions for facilitating the propagation of this valuable grass are striking; but still I am afraid they do not remove the difficulty, so far as we would wish.

You speak of letting the seed drop and lie, and digging the surface of the soil in the fall, to cover them. When they come up in the following spring, you transplant them where you intend them to grow. Now, according to my observation, this plan, in the usual close way of planting, is only practicable during the first and second years of its growth; before the grass has spread much, and before it has taken on its wonted luxuriance. On my lot, which is high sandy land, and not very rich, after the second year, if I do not cut it, but leave it to go to seed, the sward becomes so rank, and covers those spaces between the drills so densely, that it would be absolutely impracticable to dig the ground under it in the fall. Indeed, it is with no inconsiderable trouble that we can wade through it to gather the seeds from their spikes. And moreover, if I ever had a crop of young plants in the spring, under the deep and heavy bed of dead grass that covers the ground,

---

* See Farmers' Register, vol. iv. p. 581.

it would cost a good deal of labor and pains to remove it, and get at them. As I before said, therefore, it seems to me this plan will only succeed during the first and second years of its growth; and whilst it is yet not very prolific of seed. Or perhaps the difficulty may be obviated by planting in rows very wide apart, in a lot purposely set apart for the purpose of raising young plants.

Your other plan of taking up plants of two or three years' growth, dividing and transplanting them is, doubtless, perfectly practicable. I have, myself, divided a tussock into seventy good plants. But as you say, if they will only furnish thirty, then, twenty-nine-thirtieths of seed will be dispensed with: or one bushel of seed may be made to plant as much in this way, as thirty bushels when planted from seed in the ordinary way.

This plan, although not difficult, must, nevertheless, be rather tardy; but, as you justly remark, when we consider the great value and durability of a lot, when once set with it, the objection dwindles into insignificance.

The whole tenor of your letter is so apposite to the subject, and so well calculated to encourage the culture of this grass, that I must beg your permission to send it to the Southern Agriculturist for insertion. And as articles of this description lose nine-tenths of their value and authority by appearing anonymously, I hope you will permit it to be published with your name.

I am, dear sir, respectfully, your most ob't.

JAMES DAVIS.

CAPONS.

In the last number of your highly useful periodical, I observe an article very properly recommending the production of capons, by our farmers and others, for the city markets. Your correspondent has the merit, so far as my knowledge extends, of first publicly noticing this important matter of agricultural economy. I say "publicly" noticing this matter, inasmuch as several gentlemen of my acquaintance have in various ways endeavored to accomplish this desirable object; but, I regret to say, without the least approach towards success.* Fowls have been by them operated upon in the West India mode, by puncture, and in the Chinese and European manner, by incision, but so far the result has been death to the animal, or its nature unchanged. They have endeavored to get information from books, and have even had the assistance of those who *say* they performed the operation frequently in Europe, but notwithstanding all of their attempts at mutation, the object has not, in a single instance which I have heard of, been effected. I am aware that in the West Indies, China, Western Europe, and other countries, women and children are successfully employed in this kind of surgery, but it somehow happens that I have never seen a capon in this country; although I must confess that I have frequently heard of them, and with your correspondent "Civis" understood that the art was "easily acquired." Mrs. Glasse, in her directions for cooking a turbot, says, you must "take him;" and I should, by parity of reasoning, suppose that to eat a capon you must first *make* him. Now will our friend "Civis" put us on the right tack between this and next August, by which we may, in the course of another year, both take and *eat* of this delicious bird. If he feels the same interest which myself and many others do, he will doubtless comply with the request. I also agree with "Civis" that it may be made a profitable business in this country, and may hereafter endeavor to point out the mode whereby persons with a very small capital, near our great cities, may make a livelihood, if not a fortune, in an easy manner. It should be remarked, that the operation is not confined to the dunghill fowl, but that it is successfully extended to the turkey, goose and duck, both male and female. Should your correspondent find leisure to give us his experience and the *modus operandi* in your next or the succeeding number, I shall then endeavor to offer some suggestions which may be profitable to our farmers and others.

RUSTICUS.

PEACH-TREES.

Sir--By an error of the press, the latter part of the communication at page 308, "on planting peach-trees," is rendered unintelligible; the manuscript reads thus:—"The subsoil of Jersey is ferruginous and acidulous; lime and the calcareous earths, are correctors of these evils."

The worm in the root of the peach-tree and the excrescence on the branches of the Morello cherry, are not the *cause*, but the *effect* of disease, which arises either from a poisonous subsoil, or an exhausted surface; the cure might be effected by carefully removing the soil about the roots to a considerable depth and distance, and replacing it with fresh rich mould, with which lime or calcareous earth has been well mixed. The *old folks* understood well the advantage of this treatment, for at the 7th verse of the 13th chapter of Luke, we find the dresser of a vineyard petitioning the owner to let the fruitless fig tree stand another year, "till I shall dig about it and dung it;" and I knew an excellent farmer, who, at the time of killing his hogs, reserved the blood, with which to dress his fruit trees; and this he did, by opening the ground about the roots, and pouring it upon them, closing the earth over it. And when, through age or infirmity, he found it necessary to remove a tree, he was careful to take away the earth in which it had grown, to a considerable depth, and replace it with the best mould he could procure, always mixing lime with it, and into this the young tree was planted. I have even known him to lay a pavement in the bottom of the hole before filling, if he found that the roots of the old tree had penetrated to a wet and sterile subsoil, to prevent the young tree from throwing its roots so deep. And for this man also, as well as for Mr. J. Reeves, (see p. 297) *peaches would always grow*. His trees were so strong and healthy, and full of foliage, that they could bear a little frost, and throw off an attack of blight, which would be sufficient to prostrate the hopes of his neighbors for the whole year. The disease called the "yellows," I am confident, arises from the cause above mentioned.

AN OLD FARMER.

From the Farmers' Cabinet.

POULTRY.

"She that won't stoop to pick a pin,
Sha'n't stoop to pick a bigger thing."

For many years past, there has been a great demand for poultry and eggs, at high prices, and it seems likely to continue; for the causes which produced it are still in operation and are likely to continue and increase. The increase of steamboat and railroad travelling in our country has produced an increased demand for all the luxuries of the table, beyond the current means of supply at moderate prices; it therefore becomes the interest of farmers to devote a little more attention to producing those articles which always sell readily and at a good price; particularly as the labor connected with the rearing of poultry, if labor it can be called, is light, and can be performed by the younger members of a family, without infringing on the time devoted to the more important labor of the farm. It is an agreeable relaxation, if engaged in in a right spirit, and has connected with it many pleasant associations.

It should be the care of those who engage in the business of rearing poultry on a large scale, to study sound economy in feeding them, otherwise they may be disappointed in the expected profit. With some there is great carelessness and waste apparent, particularly in feeding with food of a more expensive character than is necessary. Having seen large quantities of poultry raised and fattened for market principally on boiled potatoes, I take the liberty of directing the *girls*, who are your readers, to it; hoping that daily, when they boil potatoes for family use, they will put enough in the pot, over and above what may be necessary for the family, to feed the chickens till the next day, and so continue it from day to day, occasionally alternating it with other kinds of food for a relish, and depend upon it you will find,

"That a penny saved, is two pence earned."

Q.

From the Genesee Farmer.

TURNIP DRILLS.

The expense or difficulty of procuring good drilling machines, induces many to sow their turnips broadcast, and thus in some degree to diminish the crop, by the want of evenness or regularity which attends broadcast sowing. Others, with considerable labor, drill all their turnips by hand, without the assistance of a machine. In this case, the most tedious part of the operation is dropping the seeds evenly. Where hand drilling becomes necessary, this part of the work may be greatly facilitated by a method described in a former volume of the Genesee Farmer. A hole is made in the bottom of a tin cup, of just such size as to allow the seeds to pass freely through when it is shaken; this cup is fastened to the lower end of a wooden rod about two and a half feet long, which serves as a handle, and the operator passes along the drill with an even pace, shaking the cup constantly and thus dropping the seeds evenly and expeditiously. The disadvantages are, that it is requisite to draw a furrow previously, and afterwards to cover with a hoe. If the land is well prepared, several furrows may be drawn at once by means of a horse attached to an instrument for the purpose, somewhat resembling a large heavy rake head, with short blunt teeth. The teeth of a cultivator, inserted into such an instrument, are still better. In this way a man may plant from one quarter to one half an acre a day, the quantity varying with the distance of the drills from each. But with a good drilling machine, he may sow and cover the seeds equally well with one-tenth of the time and labor.

Many entirely neglect the culture of turnips from the difficulty of procuring suitable drills; and on the other hand, this difficulty is owing in a great measure to the very limited extent to which they have been cultivated. Attention has not been sufficiently directed to their construction. Nearly all the patent machines which have hitherto been offered for sale, without possessing any very decided and exclusive advantage, or any thing truly valuable but what was known long ago, have been offered at unreasonably high prices. It is true there is always an advantage in purchasing implements and machines ready made, as when made by the quantity they can be furnished much cheaper; but a turnip drill, sufficiently good, need not in any case to cost more than two or three dollars. A good mechanic can easily make one for this sum. To enable the farmer if necessary to contrive and construct one for himself, or under his own direction, the following imperfect suggestions are furnished.

Drills, for sowing turnips, are driven by the hand, and sow one row at a time. They resemble in form a light wheelbarrow, being pushed before the operator. As but little strength is required, and as lightness is indispensable to ease in working, the circumference of the wheel may be of stiff hoop iron merely, and kept to its circular shape by the usual number of spokes from the centre. The contrivance for dropping and covering formerly consisted of three parts, one for ploughing the furrow, a second for dropping, and a third for covering the seed. These parts are kept separate in some drills now constructed. But the most simple contrivance is where these three parts are united. This is effected by making the dropper, or hollow wooden piece through which the seed descends to the earth, similar in shape to the coulter of a plough. Two or three inches of the lower extremity runs in the earth, and is cased with sheet iron, so as to be more easily pushed forward through the soil. This, being open at the bottom and behind for an inch or two upwards, suffers the seed to pass freely out, below the surface of the earth, and as soon as the dropper passes the earth falls upon the seed and covers it. The depth of planting is regulated by the operator by means of the handles of the drill. Most drills, both in England and in this country, are now constructed with these three parts thus combined.

A contrivance for more completely covering the seed consists in adding several short chains to the drill, which, by dragging after it upon the seed; effectually rake them in. Unlike a toothed harrow, these chains do not become obstructed by sticks, straw, &c.

In most drills, the dropper immediately follows the wheel; but in some it precedes it, the wheel being made broad serves as a roller to press the soil upon the newly sown seed.

The chief difference in drills, that which constitutes the chief variation in the different patents, and which is still least perfected, is the contrivance for dropping the seeds evenly from the hopper. In one of the simplest, the vessel for holding the seed, is a short cylinder with a horizontal axis, made of sheet tin, and with a number of holes in its circumference for the seed to pass through; this cylinder is kept constantly revolving by the motion of the drill. An improvement in this, consists in making the seed box of the shape of a very short cylinder terminated at each end by a cone; and the dropping part consists of a separate ring or short open cylinder of tin, sliding closely on the cylindrical part of the seed box. Several rings, with holes of different sizes, for different kinds of seeds, may be thus used on the same machine. Rotary motion is given to this cylinder in two ways. In one the machine has two wheels, the seed box being placed on the axle between them and revolving with them. This is recommended for its great simplicity. In the other, a strap passes from a small wheel on the axle of the main wheel, to another wheel on the axle of the seed box. The motion of the seed box may be increased or diminished by varying the size of the strap wheels. This contrivance is well adapted to sowing all kinds of round smooth seeds, as turnips, peas, &c.

In another contrivance, a circular brush, kept constantly revolving, sweeps against the seed holes, and keeps them from becoming clogged by driving the seed through. In Robbin's planting machine, this principle is modified by substituting a snapping wire spring for the brush. This is adapted to irregularly shaped seeds, as mangel wurtzel and corn. But it is liable to get out of order. A simple and certain method of throwing out these seeds evenly, is yet a desideratum.

SMITH'S EVER-POINTED STONE-CUTTING CHISEL.

The ordinary chisels used for dressing and cutting-stone very frequently want sharpening, which is an operation requiring time, judgment, and expense; having, when blunted, to be forged and sharpened and afterwards hardened and tempered. A machine-maker of the name of Smith, in this town, has lately invented an ever-pointed chisel, which will, I think, soon be generally adopted, provided it be made cheap. It is in fact an application of the principle upon which Messrs. Mordans' (or rather Mr. Hawkins') ever-pointed pencil is constructed. A thin plate of well tempered steel, of the width of the chisel required, is placed between two cheeks of iron and held tightly between them, by means which I shall describe. The point of the thin steel projecting beyond the ends of the iron cheeks, forms the cutting edge of the chisel; and as soon as the edge which projects is worn away by the friction of the planing stone, the steel is advanced between the cheeks, and the edge is thus immediately renewed. To prevent the steel plate from slipping sideways, there are studs on each side of it, on one of the iron cheeks, which go into corresponding holes in the other cheek. The whole is held together by a collar or mortise slipping over, and hammered up tightly, the cheeks being of a wedge shape. When the mortise, or collar, is driven properly home, a groove therein coincides with a groove in the cheek of the chisel, and a wedge being put into the hole thus formed, holds the whole chisel tight; and prevents the mortise from being shaken off by the blows of the mallet.

At the top of each cheek, on the inside, is the half worm of a screw; between these, a screw is inserted, the end of which touches the top of the steel plate; and on being turned down with a screw-driver, or otherwise, forces the steel out from between the cheeks for renewing the working edge.

I hope I have described the thing clearly enough to be understood by my brother masons and your readers, without the aid of a drawing: my hands are too rough and stiff with handling the mallet and chisel, and moving our hard native stone, to attempt the draughtsman.

I am, Sir, yours respectfully,

A STONEMASON.

Bradford, Yorkshire, Nov. 28, 1837.

EFFICACY OF LIGHTNING RODS, OR CONDUCTORS.

By F. Maceroni.

I perceive that a question is mooted at the meeting of the British Association for the Advancement of Science, whether in the case of a certain "monument 140 feet high, erected on the summit of a mountain 1,400 feet high, augmented safety or danger, would be the consequence of attaching to it a conductor or paratonnere?" I am induced to call the attention of your intellectual readers to this passage, as I am very sure that the subject is of great importance to society. About six months ago (vol xxvi. p. 367) you honored me by giving insertion to my account of a safety gunpowder magazine, in which I speak of lightning conductors, and to which I would request your readers to refer. There is just now a gentleman, one Lieutenant Green, of the Royal Navy, who is endeavouring to convince the public by his writing, that conductors are prone to cause the damage they are intended to avert. I must say, that I regard this statement as a mischief, for I have seen too much of the saving power of conductors not to wish that every house in Great Britain were protected by one.

Lieut. Green, in his anti-paratonnere pamphlet, lately published by Tanner, of New Bond street, tells us of fifty churches in this country having been lately struck by lightning, because they had metal vanes! To be sure—but metal vanes are not conductors; and conductors should not be formed of a wire scarcely bigger than a bell wire. In my above quoted article, I have stated, that a tube is better for a conductor than a solid rod, because it is to the surface of bodies that electricity adheres. Nothing could be fitter for the purpose than iron gas pipes: but their connexions and attachments, down the building must be of stone, or other non-conducting materials.

Previously to the church of St. Peter's, at Rome, being protected by numerous conductors, by the French government, damage was continually being done to the upper part of that stupendous edifice; but never was the least injury inflicted after the application.

It must be borne in mind, that an elevated and efficient conductor will give its protection more frequently in perfect silence, and unobserved, than by conducting into the ground, or water, a positive discharge of electric matter, accompanied by a flash and thunder. The many-pointed conductors will silently draw off the electricity from a passing cloud, without any discharge, properly so called, so that the blow has been parried if it be not a *bull* to say so, before it is struck.

During my several sojourns at Rome, I have made particular inquiries into the effects of lightning on St. Peter's church. After the numerous substantial, many-pointed conductors were affixed to the summit, and most substantial, and most prominent angles, by the French in 1808, an electric discharge was not known to have fallen upon it more than three times, and then it did no injury. It appears that the clouds, in passing over the church, are deprived of their plus electricity by the conductors, just as a Leyden jar is silently equilibrized by the presentation of a metallic, pointed conductor. How many ships would be saved from damage, conflagration, and, perhaps, instant submersion, by properly constructed vehicles for conveying the electric fluid over the sides into the water? What inconvenence could be felt, from a branched rod and a chain from the mast-head, hanging along the shrouds into the water! All the failures of conductors arise from their want of sufficient mass of metal. A zinc chain, or tube, would be far less liable to oxidation than iron; and, as I have before remarked in the case of a powder magazine, &c., the metal might easily be kept with a clear surface, by an occasional rubbing with a brick-bat. About London we see conductors not thicker than a quill, applied to shot towers, tall chimneys, &c., whereas they ought to be gas tubes of at least an inch in diameter. The top ought to be formed in the manner of a branch of a tree, with five or six points of copper gilt, the extreme points being of pure gold or silver, as are those at Rome.

In some volcanic districts, over which it would appear that the solidified crust of our globe, which covers the yet incandescent mass, is thinner or more porous, than at other points, the electrical exchange of compliments between the earth and atmosphere, are almost as frequently directed upwards from the earth to the clouds as in the contrary direction. Even against such upward discharges, the conductors inserted in the earth and ascending to the summit of the building, will preserve them from injury. I have witnessed a great many instances of ascending streams of electricity, some of which I have remarked upon in your pages, particularly in Nos. 401 and 402; and I am induced to think that we should see many more exhibitions of the process, were it not for the trees which act as silent conductors, both upwards and downwards. Electricity is the real food of plants which they absorb through the innumerable points of their leaves and branches. On the same principle should a lightning-conductor be constructed with as many points as convenient.

Lieut Green says, "seventy-nine churches in Great Britain have in a few years been struck, some of them destroyed; many, after being furnished with from one to four conductors. All of of those struck had metal vanes." How "many out of the seventy-nine churches, were furnished with conductors, this opponent to Benjamin Franklin does not tell us. He only shows the danger of metal vanes inviting the lightning, without a conductor to take it away. A bit of wire attached to the walls by iron eye bolts, or staples, is certainly more likely to cause mischief than to give protection. A proper and elevated conductor will generally carry off the electricity silently, without any apparent discharge.*

From the Farmer's Cabinet.

INJURY FROM DESTROYING BIRDS.

The culture of the earth is the most primitive, natural and extensive employment of civilized life. It brings with it cheerfulness and affluence, and fosters them under its broad wing; never deserting nor weaning them from its parent protection. Every wise observer of cause and effect can tell that its increase in honor as an employment, and in profit as a support and source of individual and national prosperity, is a great result and criterion of refinement. A vagrant life and subsistence, like beasts of prey, by the uncertain toils of the chase, are the untaught evidences of ignorance and barbarity; hunting and fishing, but the instinctive resorts of human nature in its wildness.

The teeming dust from which Omnipotence framed the wonders of our animal economy is a fitting and proximate source, whence we might hope to derive its nourishment. The savage of the wilderness permits the land over which he roams to lie fallow; only because ignorance has sealed to him the letter and effect of that revelation which declares, "God formed man out of the dust of the ground." The unfoldings of that revelation, its diffusion, and the gradually increasing light of its expanding beams, have been ever the heralds, and cause of civilization, and with this agriculture goes hand in hand. The past, in all its manifold views and bearings, gives the proof of experience to the remark; futurity will sustain it by bringing to pass the prophecy concerning Christianity and the effects of its spread; "they shall beat their swords into ploughshares, and their spears into pruning-hooks."

---

* *Note.* The above article is inserted because the fact stated respecting St. Peter's Church is deemed important; it otherwise assumes as facts what requires to be verified.—*Ed.*

But agriculture is not only the most natural, it is also the most alluring and pleasant of the myriad pursuits of humanity. The variety of the apartments and furniture of nature, the glory of her colorings, the fragrance of her odors, and the ever varying hue and aspect of her seasons, are the great fountains of a variety, without which the existence of a changing and change-loving creature, would be a terrible monotony. It is pleasant too to plant in hope, and to watch through years of youth and bloom to decay. It is pleasant to train the vine, to pluck its ripening clusters, and to repose in the shade of its spreading greenness. It is pleasant to anticipate through winter, the flowers, the dew, and the bright sky of spring. It is delightful to view the waving fields ripen unto the harvest. And though in turning the rank and reeking soil we may remember with a sigh that we are moving the wasted mould of many a one once as free in thought and life as him who guides the plough, the next flower that attracts the eye will chide our useless melancholy.

But we would not run wild with a general view of a theme so enticing to thought and fancy; we would but pursue a branch, a single, small, but important and prolific branch of this extensive subject; one which, though in its mention it may seem paltry and trifling, richly deserves a discussion among other branches which have received attention, to the exclusion of this, only because they are more superficially apparent.

This subject naturally presents itself in the two following divisions—and they will embrace the consideration of the whole object which we have in view. 1st. The intimate connexion which exists between the interests of agriculture, and the increase and diminution of our indigenous birds, and the injury resulting from their wanton and indiscriminating destruction. 2d. The best means of putting an end to this injury with its cause—and as far as possible in the limited space which is allowed us—we will endeavor to prove that these topics are not by any means to be overlooked and slighted in the different views of the general subject of agriculture.

Those who believingly adopt the atheist theory of a chance creation, must in consistency discard that ultimate doctrine of Christianity, that every thing, however diminutive it may be, is formed for some end. We are glad that we differ from them. We rejoice in believing that every existence, animate or inanimate, is a member of a vast and united family of servants and worshippers, that nothing is formed in vain, that every atom has its task to perform, as surely as every spirit an account to render. Idleness is an unnatural word coined to describe an unnatural propensity. In the wide sense of subservience to a divine design, the world knows not the term, nor the trait which it describes. There is nothing idle, for good or for evil, for weal or for wo, rearing or casting down, building, or bringing to nought, for judgment or in mercy, creation is a vast and faithful agent doing the biddings of an Almighty and Omniscient Governor. Our subject is intimately connected with the idea, let us apply it more practically.

We think we may say, without fear of contradiction, that none of the birds of the air, not even those which are now most sought, for that purpose, were originally created expressly for food, and yet that seems to be the only light in which we regard them. Our first parents and their posterity, till after the flood had ravaged the earth, and changed our race and the laws of life and conduct under which they were created, were forbidden to eat of that which had life. The whole animal kingdom was interdicted as food; a fact which modern epicures may believe with wonder. And even now, when by permission rather than command, the primitive rule is abandoned, and we destroy life to appease the cravings of hunger, thousands of species, both of beasts and birds bear, whether rightly or through mere caprice, the character of uncleanness. Nay, even of those of the feathered creation, which do not come under the latter class, a vast number are too small and worthless to be seriously sought for as food, too diminutive and paltry in appearance and availability as conducive to subsistence, to reward the labors of those who would look to them for a supply of their wants—unavailing as far as any direct influence upon man is concerned but to please his eye, and thrill his ear with their melody, and yet it is with these smaller members of the tribe that we have now, chiefly, to do, in pursuing our subject. These diminutive and seemingly worthless, though pretty creatures, are, strange as it may seem to those who think that to kill them is so pleasant and agreeable a sport, of immense advantage in the great design and economy of nature. That these species, then, were created at first, or are now permitted to exist and increase, merely to supply food to our race, is an idea, which any one but he who is endowed with a Lilliputian mind or appetite will discard. For what then were they formed? for certainly they are the work of design—the produce of a hand whose omniscience covers at an onward glance, the whole existence of the object he is framing. What is there in the great business of the universe? With the solution of this question we open up our subject to the reader, and give it forth to the agriculturist from its obscurity, as a subject worthy, at least, of thought.

The nature and habits of birds, are as widely different, as those of the more familiar, because more accessible beasts, and therefore we would not be understood as saying, that all, even of these more diminutive species, are useful to the farmer. It is not so. Some are of no use, others decidedly injurious, and with the latter we would hold no terms; we would say, destroy them in any manner, which in itself would not do more injury than it would prevent if successful—but a large number of these creatures are most useful and faithful servants of the tiller of the ground. And that is not all; their labor is manifold. A great multitude unite with some of the beasts and larger birds, in doing the vast and indispensable duty of removing the impurities of decaying vegetable and animal matter which but for them would be a much more prolific source of miasma and disease. They are the great unpaid and unthanked scavengers of the earth. While myriads, as we have said before, are the assistants and ready instruments of the farmer, and through him of mankind. Let him who would derive information to stengthen our remark and his own convictions, consult the natural history of this curious and beautiful race—and his doubts will vanish and give place to a light which should long since have shone upon him and guided him in reference to this matter. He will find that almost all our most common and numerous birds nourish themselves and their young by the insects which are so destructive to greenness and fruitfulness—a very few species, to which we have referred before —destroy the useful produce of the earth, and even they do not half the injury which is caused by the trespasses of their paid slaughterers. But their ravages are far overbalanced by the multitudes, and they the most persecuted because the most inoffensive and exposed, whose sole occupation is the rearing of their broods and the instinctive search for and destruction of these insect enemies of vegetation—the worm which consumes and corrodes the thriving and spreading root—the fly which wastes the green and shady leaf—and the myriads of other tiny but baneful creatures—the almost microscope vermin of our fields and gardens, which canker, decay, and disease, if they do not devour, the tender and budding plant—and which are only less in number and less formidable than the locusts of Egypt because of the services of the race which some look upon as only made to be destroyed.

But let us further inquire, if we would have still larger and more impressive ideas of the importance of our subject, what are the most numerous and general causes of the great and distressing fluctuations in the quantity and quality of the produce of our fertile and almost illimitable country, and the necessarily consequent variations in those branches of our commerce of which agriculture is the more direct and immediate parent, and even in those which are more remotely connected with it. What destroys, year after year, the growing fruits of many a faithfully wrought garden, the luxuriant and hard earned grain, of many a waving field, nipped in their bloom and consumed in their beauty and promise by some untimely, and, alas, increasing cause. The great staples of many of our states are wasted and ruined too often to allow of supineness upon the subject. We would point a finger, which would warn while it instructs, to the teeming answers to the questions we have proposed, which stand forth in the numberless paragraphs which the journals of many a season of want and hunger unfold, and which tell sadly of a cause and effect, in regard to whose prevention we are powerless, without the aid of the persecuted tribes whose services we have been eulogizing. And what is still more alarming, as the hum of business and settlement increase, as the mouths which are ready to devour the produce of the soil become more numerous and clamorous—the cause of this want is increasing, and its only remedy becoming every day less proportionate in power to the duty which it performs. It is a gloomy thought, but gloom is not enough; the evil is serious, but like other evils whose progress is slow, and whose causes are minute and ramified, hey are not duly appreciated; the subject needs combined reflection and steady action. Let our remarks especially impress on the young the thought, that every missile aimed in sport tends to take food from the mouths of the poor and famishing—that if successful in its aim it destroys its pretty victim, however small in proportion may be its immediate and perceivable effect—it deprives the agriculturists of the life-time labor of one faithful servant at least, perhaps of more who perish in a deserted nest. Let them make him remember that every swallow which pierces the air, so long the sprightly mocker of his ambitious sportsmanship, so long aimed at in hope, but perhaps in vain while on the wing, but slain in revenge when it alights to rest, is making more sure and effective the seed of the sower, is surely increasing the bread of the reaper, and food for industrious poverty and national wealth. The race was not formed in vain. Each one has its task to perform; we sin in wantonly destroying them, first against him who made them for his glory, then against ourselves, willingly ignorant of their untaught "labor of love."

We would apeal, then, to the young, to most active and thoughtless enemies of the feathered creation: to the rising generation, the hope of the country, who are unwillingly, and perhaps, as far as motive is concerned, innocently doing that country which it is their high ambition to serve, an injury, which is irreparable, and deep. And what is more directly interesting to themselves, though perhaps not so deserving of thought, they are by every act of destruction, injuring that disposition, and those sensibilities, which are so lovely in many of the young, but which is lost as manhood steals apace, perhaps by the united indulgence of this and other hardening habits. If to such an aspiring youth, joyful and giving joy, in the glad hope and promise of future usefulness, the soft intercession against cruelty, of a tender mother or a fond sister, come in vain, or are derided and disobeyed, as the weaknesses of feminine hearts, we would offer the higher and more sacred consideration, that if they are too manly to yield to such mild petitions, they should be manly enough to feel and to be proud to feel, a responsibility for their country's welfare, breaking in with every ray of knowledge, and beating with every pulse of young and buoyant life. They are not too young to be gladdened and ennobled by the thought that even they are contributing their mite, and that in a comparatively important way, to national honor, growth and advancement. We appeal to all their warm and peculiar feelings which can be brought to bear upon the subject, that we may induce them to give, if not their positive assistance in helping on the work of reformation in this respect, at least their negative aid in restraining their own strange propensities and temptations to slaughter, for amusement, this useful race.

If then, these creatures, when considered collectively, are of so much advantage and profit to the cultivator, and have so important a connexion with the agricultural interests of the community—if their destruction is so widely and inconsiderately carried on, and their decrease so rapid and alarming—if the fact presses upon us that even in this the youth of our government, when our jubilee of republicanism has scarcely passed, and in this thinly settled state of our country, we are fast losing from eye and ear the flight, the song, and especially the services of these feathered fellow-workers in the culture of the soil—if they are fast disappearing from among us and around us, fast yielding to the hum and the danger of crowded settlements and busy and wanton life, and leaving their annual work undone—we must awake; as a great agricultural people we must awake, and look to our interests; we must protect these servants in their old habits and employment

—or we will gradually, but irrecoverably lose their services. With these reflections we are brought to the remaining part of our subject—is there no remedy for the evils we have described?

And first we would propose the attainment of this great object, to the parents, guides and preceptors of the young—they are the great fountain head of effort, the sources of deep and well directed endeavor. We would propose it to them as patriots, as friends and upholders of the stalwart farmers of our country, the strength of the community, the honor of our government, and especially as affectionate well-wishers to the youth over whom they have the charge and oversight. They must feel its importance; let the feeling guide them in social counsel, training and government. Let them teach, with other more usual branches of instruction, the sin and folly of the species of cruelty which constitutes the injury complained of; and we need not look beyond their labors for the remedy of this evil. They are supreme, each in his own circle. Let them in kindness, but with unyielding steadiness, perform toward their offspring, this with other family duties, and the work is done. But we are not over sanguine in this view of the subject. United and combined effort in this quarter, cannot be reasonably expected. Truth may take root and flourish here and there; but as for a general and immediate attention to the object proposed—it is scarcely thought possible, at least it is improbable.

Again we would appeal to the self-interest of owners and cultivators of land. They must, surely, be ignorant of the injury which is in progress, when they allow it to go on unreproved before their eyes. We would appeal even to their own selfishness and love of gain, if no higher motive will reach them, and entreat them as their influence gives them opportunity, to give themselves to a work, the first consequence of whose success will be their own welfare, the second the welfare of their country. They are supreme, each one over his own territory, be it large or small. Let them resist and punish every trespass of the wanton slaughterers of birds—let them declare war against the whole tribe of truant murderers, whose daily sport is the spoiling of the nest, the invention of new and the use of their old and destructive snares, and the more immediate devastations of gun and bow, and missile. Let our sturdy farmers hold themselves forth as steadfast resisters of every such act, and more particularly of every entry, for this purpose, upon the lands for which, as stewards of our country's prosperity, they are more immediately responsible; let them do this work with all their might, and again we say we look not beyond them for ultimate success. To encourage such an action, to make it more universal and more strong, to embody public sentiment, to warm to feeling and exertion by comparison of views and mutual counsel, to reciprocate alarm and warning, to give a salutary tone to public aim, and to throw a greater light upon the subject, the assembled strength of our agricultural community might do wonders. Let them meet in their power and give a start to the object in view, a fair experiment to the means which lie in their own power as teachers of the young and possessors of the soil, and some good may be done—the ball of reform may be set in motion. But as we have said before we are not over-sanguine in our hope concerning the success of any or all these schemes and appeals; we look high for the source of assistance and remedial action, to which we think the way lies clear, our readers will pardon us if we retrograde in presenting it.

To foster and protect the agricultural interests of the community is a high and sacred duty of every government, but especially of one which boasts itself republican. Agriculture, to use the language of another, "is the breast from which the state draws its support and nourishment;" and we may add, it is the great index of prosperity and refinement. It is the great popular pursuit. The resource of indigent, but enlightened industry; the reservoir of large and busy, but stable capital; the mild seducer from idleness and worthlessness; the quiet and honorable retreat of reformed or high-minded poverty, the first love of those who grow weary of the crowd and hum of a city, the last love of those who retire upon wealth or a competency. It should be the protegé of those in power, the representative of constituents who are its zealous votaries.

We look then to legislative enactment for our remedy. It protects game for sportsmen, who disregard all fear of trespass in its pursuit. In many states it offers a large reward for the destruction of the noxious birds, whose numbers are small, but whose paid destruction is of evident injury to the farmer! Those who take advantage of the bounty offered being, usually, miscreants who care no more for the laws of property, than for the lives of the myriads of serviceable birds which fall in common with the prescribed species. We look to legislative power for the uprooting and extermination of this evil. Will not our representatives protect their constituents and their country?

We will not stay to specify the particulars of the law which we would wish to be fulminated against this evil. We would only say that with half the ingenuity which is yearly expended upon more favorite enactments, the power of offended government might be readily brought to bear upon offenders, by a well-contrived system of rewards to discovery and prevention, and punishments to transgression. This, united with and enforced by the labors of possessors of the soil, and trainers of the young, would soon be effectual, in the attainment of our object.

In concluding these remarks will the reader pardon us in again reiterating the importance of the subject. The evil done by insects is often unseen and unknown, but enormous; the number of their destroyers is fast decreasing, and can never be renewed; without them we are helpless; and agriculture deprived of servants and services which cannot be replaced.

From the Journal of the Franklin Institute.

ON THE INCREASE OF TEMPERATURE IN THE INTERIOR OF THE EARTH.

M. Arago has lately communicated to the Academy of Sciences the result of the thermometrical observations which he made, on the first of May last, in the well which is now being sunk at the slaughter-house (Abattoir) of Grenelle. The boring has now reached the depth of 1312 English feet. The bed of chalk in which they have for so long been engaged, is not yet traversed, but the numerous flints, which were unceasingly met with at lesser depths, have now disappeared. The city of Paris has determined that the boring shall continue to the depth of 2295 English feet, if the spouting water be not found sooner. It is presumed that the water which will issue from so great a depth will possess a temperature of between 93°2 and 95° Fahr., and, in that case, it might be employed for hot baths, &c. But however this may be, we shall now adduce the thermometrical observations which have been made at the depth of 1312 English feet. On the 29th of April, at 7 P. M., four instruments were sent down, viz. two of M. Bunten's self registering thermometers, one a *diversement* thermometer, which M. Magus, of Berlin, had recently sent to M. Dulong, and another of the same construction, manufactured by M. Walferdin. The two first were contained in a copper tube, in which they were secure from the pressure of the water; the third was open at the top, but in such a manner that the pressure could not alter its form; and the fourth was enclosed in a glass tube, which was hermetically sealed. These four instruments, after having remained for about thirty-six hours in the well or bore, were removed from it on the first of May, about 7 A. M.; they then indicated the following temperatures:—

The first thermometrographe of M. Buten, - - -	74°.3
The second, do. - -	74°.21
M. Magus' thermometer, á diversement, - - -	74°.30
M. Walferdin's do. - -	74°.66

Assuming, then, 74°.3 Fahr. as the temperature at the depth of 1312 English feet. if you subtract from this number that of 51°.08 Fahr., which indicates the mean temperature of the surface of the earth at Paris, 23°.22 will remain for the increase of temperature, corresponding to 1312 English ft. of depth, or, what comes to the same thing, 1°.8 Fah. for 101.2 English ft. If we take the case of the observatory as the starting point for the temperature where it is at 53°.06 Fah. 21°.24 Fah. will then be given as the augmentation for 1222.5 English feet, which corresponds to 103.348 English feet for each centigrade degree.

From the Farmer and Gardener.

BUILDING STONE FENCE.

Much error has prevailed in the manner of building stone fence, and error in this matter is attended with serious loss to the farmer, since there is no kind of fence, in ordinary use, so expensive, and if well built, so cheap in the end. A few observations upon this subject may not be amiss to those who are desirous of constructing this fence.

The first material error, but too common, has arisen from giving to the wall too wide a foundation, as much as 3 feet, $3\frac{1}{2}$, and sometimes 4 feet, and then by drawing it in, or to use a mason's term, battering too much. Two evils spring from this mode of building; the fence is very apt to bulge, or split in two, and the facility for sheep or hogs to run over it, is as obvious as the fact itself is common. Again: fence built after this manner takes more stone than is really necessary, and however abundant the material may be, the mode of construction is radically wrong. The fence, which I have as yet built, about 200 yards is after this fashion: $2\frac{1}{2}$ feet wide at bottom, and $1\frac{1}{2}$ at top—height $4\frac{1}{2}$ feet—a trench over $2\frac{1}{2}$ feet wide, and about 5 inches deep, is first made, and rarely more so, unless on ground liable to wash, as by a road side, ascending a hill, where a deep gully has been made: on stony ground, it may be dispensed with; but otherwise it is safe to dig a shallow foundation, as the action of the frost is thereby prevented, and which, I am very confident, has proved injurious in a high degree, when this precaution has been overlooked.

A fence of these dimensions, of good stone, and built by a skilful workman, I feel well assured, may endure for ages. But the laying of the stone aright is an object of the greatest importance; without especial care in this, serious mischief will follow. As a general rule then, indeed almost invariably, the stone ought to be placed crosswise and not lengthwise of the fence (a very common practice to give it a pretty facing) and although in comparison, but few will be found long enough to go through and thus serve as *binders* yet many will pass more than half way, and so by overlaying alternately from side to side, the middle will be kept well bound, and the whole structure solid and compact. It is obvious to reason, as it has been often proved by experiment, that by laying stones lengthwise of the fence, and filling in the centre with small pieces, speedy dilapidation must take place. In short, with some modification, the rules, which govern in masonry, should be observed in the construction of this fence. Now the only material variation, which I would suggest, is this: the masons (to adopt their terms) use *stretchers* chiefly and *headers* occasionally to bind the wall; but they use mortar, and that without stint, to consolidate the structure. As masons use stretchers to give a handsome facing, and mortar to impart strength, let the stone fence builder use headers altogether, or nearly, as he cannot he allowed any cement. Let me give an example. Take a stone 15 inches long and 4 wide, or 2 feet long and 6 inches wide, and put them across the fence, instead of lengthwise; is it not manifest, that they will be infinitely less liable to be displaced? I grant that stones may be placed lengthwise with great safety, provided especial care be taken to have the next course put on transversely; but it should be borne in mind, that it is not easy always to procure stone for this purpose of sufficiently good quality, for in this case, the stone should pass entirely through, whereas if all pass inwards or across, stone of an inferior quality will make a very substantial fence.

Thus you have the breadth at bottom and top, and the height and mode of building as practised by myself. Some of my fence has been built 9 years, and is as good in all respects as when first made. In passing, it is to the eye apparently perpendicular. No animal will attempt to leap over it. On top I place flat stones the width of the fence; this prevents the smaller stones from being knocked off. If stakes and rails were put on, they would serve nearly the same purpose; in which case, the height might not be quite so great, say 4 feet 2 inches. The cost is greater than post and rail, but if *well built*, there is an end to future labor, expense and repairs.

June, 1838. A VIRGINIA FARMER.

VALUE OF DURHAM CATTLE.

The inquiry is often put—'what can justify a farmer in giving the enormous prices demanded and obtained for Durham cattle? We could easily give a number of reasons which we deem satisfactory; but at present will offer but one, which we think sufficient. A thorough bred bull may be bought, say $500, which we may assume as a fair averaging price—for the prices range from $300 to $1000. Now the point of the question is, how can a bull pay back in substantial benefits, the $500 paid for him? We will give a fair answer to the question; and show that the sum is returned, not merely in blood or pedigree, but in the actual improvement of those qualities in the animals produced from the bull, which every cattle raiser most desires. A good bull can safely serve 50 cows a season without injury to himself—and many have served from 80 to 100—but let us take 50. To put the proof to the severest test, we will suppose that these 50 cows are all of common stock, and that their calves are all destined for the butcher and not one kept for breeding. The question then is—'will the fifty calves pay in beef, a fair return for the sum expended in the purchase of the bull?' We answer yes; and, without going into any tedious calculations to show how much more beef they will make in a given time, than the common stock—or how much earlier they will mature—or how much time, risk, food, money and interest, are saved—we will demonstrate the truth of our opinion in the statement of the fact, that the large graziers of Fayette, Clarke and Bourbon, will give ten dollars a head more for half blood Durhams, at two years of age, merely for fattening for the butcher, than they will for common cattle at the same age. Now these graziers know perfectly well, the value of every description of cattle in the country for fattening, and they would not surely pay so much more for the half blood Durhams, than for others, if they were not justified in doing so by making a better profit from them. It is to be recollected, too, that these large graziers buy their young cattle—for none of them can breed one in ten of the number they fatten and sell. Now here are fifty calves, the produce of one season, whose superior qualities at two years of age, pay $500 (the price of the thorough bred bull) more to the breeder, than the same number of common cattle. It is needless to run out the demonstration further. Every farmer can calculate for himself the advantages of breeding several years from the bull—the greater the number of calves he could get than that we have assumed—the superior value of the heifer calves for breeding instead of butchering, &c.; and we believe no one who will candidly examine the subject, can doubt the economy of procuring, even at their high cost, this invaluable breed of cattle. When this breed shall become so widely diffused as to constitute the general stock of the country, then, and not till then will their price be graduated, like that of other cattle, by their intrinsic value merely for milk and beef.—*Franklin Farmer*.

From the Genesee Farmer.

SUBSTITUTE FOR SPAYING.

A new mode has been adopted, (I do not know when or by whom,) as a substitute for spaying, which is of great importance to the agriculturist. From a number of contradictory reports, and from a want of the knowledge of operating, the system met with few advocates, and for the best reason—because the instructions were to use shot, which did not answer the purpose. Instead of shot, a bullet is now used, which fully and completely answers the desired object. I have the best assurance of its efficacy, and with pleasure make the communication to the world.

Mr. Hannock Davis, my near neighbor, has tried the experiment, and the result was complete and satisfactory; so much so, that he has operated on all his young sows, to the number of fifty; they are all healthy, thriving and fat, and as barren as if they had been spayed, showing no inclination for the boar. He performs the operation by hanging the sow up by the hind legs, in the manner of spaying, and through a reed or any other tube, introduced two or three times into the *vagina*, a small rifle bullet is deposited. Any farmer can perform this simple operation with ease and perfect safety, without hunting the neighborhood for a person skilful in the art of spaying. * * * My mode of operation on a cow, and which I think would be successful, is this:—Tie your cow or heifer by the head and horns in a narrow stall, and if disposed to kick, tie her hind legs together; have a smooth stick or probe prepared, with a cavity in the end sufficiently deep to cover half the bullet, in which you will place it; introduce the probe four or five inches, elevate and draw it out, and the bullet will be left where it was designed. It may require a larger bullet for a cow or heifer, than the size used for *bulleting* sows.

From the Genesee Farmer.

DON'T BLAME YOUR SEEDSMAN.

Few things are more common than for farmers to purchase seeds at the shops, either Shaker or imported, put them into the ground in the garden or the field, and because they do not all vegetate, the seeds are denounced as worthless and the seedsman is compelled to bear the blame of the transaction. Now we venture to assert that nine times out of ten, when the seed has been purchased of a well established seedsman, the failure should be charged upon the buyer instead of the seller.

How many packages of the yellow locust seed have been put into the ground without previous preparation, and when not one in a hundred has grown, the seed has been called bad, and the seller a cheat. Now if the buyer had turned boiling water on his seed till they were swelled, perhaps not one in a hundred would have failed, and a fine nursery of trees, and a handsome profit, would have been the result.

How has the purchaser of mangel wurtzel been disappointed in the germination of the seed, and fancied that he had been imposed upon, perhaps discouraged from any farther attempt at growing this valuable root, when, had he let the seed soaked in water a little warm for twenty-four hours, nearly every one would have grown. The same remark will apply to the common beet, and various other seeds that frequently fail of germinating.

A farmer buys a quantity of ruta baga seed and sows it on stiff clay. The crop is of course a failure, but instead of placing the blame where it should be, to his inattention to the fact that such soils are entirely unsuitable for turnips, or any tap rooted plant, he condemns the seed as impure or imperfect, when, if sown on the proper soil, a deep sandy loam, the produce would have been first rate.

We have given these instances to show that when a man purchases seed, he should know how to sow them, and where to sow them, if he would be saved from disappointment. Scarcely any two kinds of seeds will succeed equally well when they receive the same treatment, are planted in the same kinds of soil, or to the same depth. Ignorance, or inattention, here frequently end in disappointment, and the vender of valuable seeds frequently receives blame, when his efforts to accommodate the public deserve the highest praise.

From the Franklin Farmer.

CHARCOAL FOR DISEASED LUNGS IN HOGS.

Mr. Editor—As the rearing and fattening of hogs has become a business of great importance to the west, and especially to our own corn-growing state; and as new and terrible diseases have made their appearance within the last few years, among that class of our domestic animals, I, as a common sufferer with my brother farmers, have been trying to ascertain the cause of, and remedy for, the one which I have suffered the most by, and which I shall call your attention more particularly to. It is admitted, I believe by pathologists, that diseases may, and do change their type in the same latitude, and become more and more malignant as population becomes more dense and the country becomes older; thus our own intermittent has degenerated into the more deadly typhus fever; thus that which we once called quinsy or swelling of the throat in swine, has now assumed a more malignant type, and requires a different treatment; the cause is the same, but the effect is not always instantaneous or accompanied by the same symtoms or results. I think it may be safely assumed that most of the diseases, if not all, that hogs are liable to, are produced by sudden transitions from heat to cold; and as they do not, like most other animals, perspire through the pores of the skin over the whole surface of the body, but through small orifices on the legs and throat, which are constantly liable to obstruction, especially in the winter season, when the animals in large numbers bed together, producing great heat and free perspiration for a short time, but from the restiveness of their nature they are often changing the position first assumed, all tending to clot the mediums of respiration, and thus lay the foundation of disease and death by alternating between heat and cold through the winter. Ordinarily the weak of the herd are the first to die. This may be chargeable to their inability to change positions, subjecting them to the crushing weight of the whole number in the bed; or to their long subjection to the great heat engendered by the common mass, until they are called to partake of the morning food. This, as we have stated, formerly produced enlargement of the glands of the animal's neck, which often ended in inflammation and death. Now, the same cause produces a very different effect, and although it is still strangulation, yet the inflammation falls with its whole weight upon the lungs, and if both tubes of that organ are affected, death instantly ensues; if only one, the animal may live a long time, but never recovers unless the remedy that I shall presently suggest, or one equally potent, be applied. The symptoms where the attack is violent, are a seeming sense of suffocation, great indisposition to move, a deep crimson color, approaching to purple, all over the body, and if forced to move only a few paces, the animal will pant as if worried by dogs in hot weather. If the attack is less violent, they will take more exercise with seemingly less pain, will throb in the flanks, in much the same way that a horse will when exhausted by fatigue and hard usage, are generally inattentive to their company, are inclined to eat earth rather than their accustomed food; such generally live a long time, but never recover. I now proceed to point out the way to prevent the disease and to cure it if taken in time: Do not suffer your hogs to herd together in large lots in cold weather; never suffer them to sleep in hollow trees; if you have sheds for them to sleep under let them be set so low that they cannot in great numbers heap together; in dry hard freezing weather let them have some succulent food, such as apples, potatoes, or turnips, but especially let them have plenty of salt and charcoal; this last is a cure for the disease above described, if administered before they entirely refuse to eat. It is known to almost every one, that charcoal is a powerful antiseptic and absorbent, and that hogs will search for and eat it with eagerness, and especially in banks of leached ashes, and so they will unassociated with ashes, if at first you will break it up into small lumps and pour a little salt and water over it. I have tried the various means in common use, such as tar, antimony, sulphur, &c., and never had one to recover its health until I tried the charcoal, and I have every confidence that it will succeed with others as it has with me, and if it does, I shall be well paid for this communication, feeling as I do, that no man ought to live for himself alone.

W.

From the Philadelphia Farmers' Cabinet.

CITRON PUMPKIN.

This most excellent and delicious article was introduced into this country by Commodore Porter, who gave a few of the seed to Lieut. Gamble, then at the navy yard in this city, who cultivated them successfully. Lieut. Gamble was transferred to the navy yard at New York, at which place he continued the cultivation, and it gradually spread over Long Island and along the banks of the Hudson.

In the wheat-growing districts of New York, it has almost entirely superseded the common pumpkin. It possesses all the good qualities of the pumpkin and squash, it is neither watery nor stringy, makes a most delicious pie, far superior to that made of the former, and goes much farther. It is also served up at table with meat, in the same manner as the squash, and, if not superior, it is certainly equal to the best of the species. For all culinary purposes it is a most superior article, and as it contains a vast proportion of saccharine matter, we are persuaded that it would be highly beneficial to cattle, especially milch cows. Another great and very decided advantage is that the citron pumpkin may be readily preserved throughout the whole winter, provided they are kept free from the influence of frost.

The seed may be planted at the usual time of planting the pumpkin in the spring. Wm. P. Jenny, of New Bedford, in a letter to a gentleman in this city on the subject, says, "They require a rich, moist soil; I planted in beds six feet across; they require considerable room, as they are great runners as well as great bearers. I have seen the ground literally covered with them. With us they frequently grow to the weight of thirty to forty pounds, and I have no doubt that they would, with proper attention in the culture, reach the weight of seventy to eighty pounds. They are in deservedly high repute with us." They resemble in shape a melon, have no neck, are easily cultivated, and in great demand, all brought to this market last fall being immediately bought up.

From the Journal of the Franklin Institute.

RUSSIAN GOLD MINES. IMPORTANT DISCOVERY.

The St. Petersburgh letters are much occupied with a discovery relative to the working of the Russian gold mines, which, if truly stated, may come to have some influence on the precious metals. A letter of the 26th ult., says, "There has been found out, it is said, in the Ural Mountains, a new mode of extracting gold from the earth, sand, or ore. The sand, or earth, has been put into a blast furnace and melted, and the most extraordinary results obtained. By washing, the method hitherto pursued in Russia, one and a half zolotnicks of gold were produced, from 100 poods of sand, &c. the expenses were about covered; two zolotnicks per 100 poods were worth working. Fine sand, or earth, rarely produced more than three zolotnicks, and five zolotnicks were quite uncommon. By the new process, on 100 poods of melted sand, they obtained sixty zolotnicks, in some cases; in others, forty to fifty zolotnicks, and on melting 100 poods of previously washed sand, they got forty to fifty zolotnicks of gold. There is little doubt of the accuracy of these statements, but what the comparative expense of the two modes is I cannot tell you, nor whether the Ural grows sufficient wood for fuel, and whether coal can be found there. One pound Russian contains ninety-six zolotnicks; 100 poods are about 3,550lb. English weight."

The Editor of the Mining Journal adds:

The importance to be attached to the new process, by smelting, of extracting gold from the ores, or deposits, in the Ural Mountains, is so considerable, from the increased quantity obtained, as will be observed by reference to a paragraph, extracted from the columns of a contemporary, and inserted in our present number, that we are induced to direct the particular attention of our readers to the subject, while it will be our province to endeavor to obtain more detailed information of the plan adopted. The vast outlay of capital in Brazil, where attention has been directed to the gold districts, and the numerous veins which are found in Virginia and in the neighborhood of Charlotte, in the United States, renders the subject one deserving of the first consideration. The process of smelting, as applied to gold ores, is not novel in theory, although we believe the present to be the first instance of its successful practical adaptation; and, if we are to credit the statement that the produce has been raised from five to fifty, or ten times the amount obtained, merely by the introduction of an improved mode of reduction, while the halvans, or refuse, have been found to contain a large produce, it is an epoch in mining, which will tend much to revive the spirits of the shareholders in the "Union Gold Mining Company," and others of a similar nature, and proves that this peculiar department of mining is in its infancy. We expressed our opinion at the time of the announced failure of the success of the "Union Gold Mines," that an improved mode, or one perfect in itself, so far as improvements then had taken place, would doubtless have yielded profitable returns, and we sincerely trust, that the present discovery will be found applicable to the ores of America, which, however, are, if we mistake not, of a different character to those of the Russian possessions.

We have here, then, an additional evidence of the affinity and importance of science being combined with practice—of the association and the advantages derived from the application of chemistry to the operations of the miner; and hence further proof of the advantages which may be fairly calculated upon from the establishment of a "School of Mines."

New process for Extracting Gold.

To the Editor of the Mining Journal.

SIR:—The following information respecting the extraction of gold in the Russian dominions, I have lately received from an intelligent and well-instructed officer of mines in the Emperor's service, and as you are properly anxious to be informed on the subject, I send it to you:—

"Knowing very well the deep interest you take in all scientific discoveries, especially in the mining and metallurgical departments, I thought it might be agreeable to you to be informed of a new discovery made in the Uralian Mountains, in the method of extracting gold from the alluvial deposits. In the official letter received in Paris, I learned that the following curious comparative experiments were made in the extracting of the gold from the sand, by Mr. Anossott:—

1. "By the common method of washing used in all countries having gold (stream-work.)

2. "By the amalgamation—the method similar to that employed in Hungary in gold mines.

3. "By the damp way, or dissolving the sands in acids.

4. "By melting the sand in the blast furnaces.

"Those experiments were made by the order of the Minister of Finance, Comte Kancrin, to the end of ascertaining the exact quantity of gold contained in a given quantity of sand. and extracting the gold from the very middle of the grains.

"By the second method; they obtained eight times more gold than by the first (common system.)

"The third method produced four times more gold than the first; but by the fourth method, that is to say, by melting the sand, twenty-four times more gold was obtained than by the washing system.

"In that process, the produce of the melting is an alloy of cast iron and gold (fonte aurifere,) from which the gold is separated by means of sulphuric acid. By putting this last method into practice, we shall obtain yearly 8000 poods (sixty-two poods equal to one ton) of gold instead of 400, from the same quantity of alluvial deposit. But the conservatory principle, applied to the national wealth of the Government adopts the plan of only a moderate increase of the annual produce of gold, and securing thus a longer existence to the alluvial deposits."

The statement as to the difference produced by the modes of treatment may appear startling at first, but it may be considered as more probable if we take into account the nature of the substance in which the gold is enveloped. The produce of smelting, we see, is an alloy of cast-iron and gold, indicating that, as is very usual, the substance accompanying this gold is iron. Now, to say nothing of the very imperfect results which can be obtained by the old method of washing, if we consider the ingenious application of amalgamation which is mentioned, we shall at once perceive, that every particle of gold which is wrapt up in iron must infallibly escape the action of the mercury, and it is not difficult to imagine, that a very considerable proportion may be so defended. Let the whole, however, be reduced by fusion, and all the metallic part will then be brought together and separated at once from the earthy part, and consequently, little or none of the gold can escape. Thus, we may account for a very considerable difference in the results of the processes that have been employed. The separation of the gold from the iron by sulphuric acid, is not likely to produce any waste of the precious metal.

It is anticipated, I know, that this improvement may be extended to other gold-producing countries, and I have no doubt but it may in due time; but it should be recollected, that smelting is a very expensive and tedious process in some of these countries, partly from scarcity of fuel, and partly from very imperfect methods for producing the necessary blast, by which it happens that the degree of heat required is difficult to obtain. Improvements may be made so as to remedy some of these defects, and one important one, I believe, would be, the application of the hot air blast; but those who know what the difficulties are in making alterations in established processes in some of the countries to which these observations are applicable, will see that considerable time may be required to accomplish the object, and the selection of very judicious and well instructed agents to carry the necessary measures into operation.

To any one who may be considering the subject with a view to adopting the use of this discovery, I would also suggest, that the chemical separation of the metals, is an operation which must be directed by one possessed of considerable skill and experience, and that it can only be done where sulphuric acid, or substances not easily transported, can be supplied in sufficient quantities. If the alloy be rich enough to bear the charge of carriage it might be better to send it to places where the requisite skill and materials can be had with facility, but here again, the fiscal regulations of different countries may oppose an obstacle.

I merely throw out these hints that persons who may wish to avail themselves of the advantages held out by this process, may be prepared to meet the difficulties that present themselves, and to set about the undertaking in a manner most likely to ensure success.

I am, Sir, your obedient servant,

JOHN TAYLOR.

Chatham Place, July 6.

NEW MODE OF APPLYING STEAM.

The editor of the New York Herald, in one of his recent letters from London, says—

A new mode of applying steam has been invented, which will do away with horse power entirely on canals. On the day of the launch last week, a small boat of forty tons was passing and repassing the river, without paddles or sails. She had a high pressure engine on board—and there she went through the water, puff, puff, puff, puff, without indicating any other symptom of motive power, or even a single ripple disturbing her course.

It seems that she has under her bottom, a single paddle, in the shape of a screw, with one turn only. To this screw is given a rotary motion by the steam engine—and its motion propels her through the water without creating a single ripple on the surface, around the boat. An experiment was made last week on the Surry canal, and it succeeded beyond all expectation. I saw the little boat myself, moving like a living creature, over the dirty bosom of the Thames. There is now no doubt of the entire success of the plan, and in less than a couple of years I expect to see the whole length of the Erie canal navigated by steam power, without injuring at all its banks. One such steamboat as I saw could take a train of thirty canal boats, at a speed of six miles an hour.

From the Genesee Farmer.

PROGRESS OF AGRICULTURE.

When the bill providing for a continuation of the Agricultural Survey of Massachusetts by the Rev. H. Colman, came up before the legislature of that state a few weeks since, a dead set was made upon it by a few individuals, who included in their denunciations, not only the survey, but all legislative measures for the promotion of agriculture, all societies, ploughing matches, fairs, &c. They maintained that it was absurd to stimulate men to attend to their own interest—that legislation was improper—that agricultural and geological surveys are expensive—in short they were wholly on the "let us alone system," a system which will do very well to talk about, but which in practice is found frequently to produce results any thing but favorable.

Their remarks called out a most triumphant refutation from Mr. Prince of Roxbury, who has from the first been connected with the most effective and prosperous agricultural society in the country, that of Massachusetts; and who for some twenty years has been secretary of that State Institution. Mr. Prince showed most conclusively that the first introduction into the state, of all the improved implements of husbandry, those that have entirely superseded the clumsy contrivances of the earlier farmers, were owing to agricultural associations, and exhibitions.

The first ploughing match in America took place at Brighton, in 1817, under the patronage of the Massachusetts Agricultural Society, and then was introduced there for the first time, Wood's patent cast-iron plough, made by Freeborn, a plough which in its various modifications has superseded all others, and so far as ploughing is concerned, (and all will admit that this lies at the very basis of husbandry) has effected a complete revolution in the ease and facility of the operation. At the Brighton show in 1836 there were twenty-two ploughs in the competition, all of which were of iron. He showed that such had been the fact with regard to drills, cultivators, machines for sowing seeds broad cast, hay and manure forks, and numberless other implements of great value to the farmer. They were first introduced by such societies; they were tested, and their operation shown at the shows and exhibitions, and they were thus brought to the notice of thousands of farmers at once, many of whom might otherwise not have heard of them for years.

The Merino, and the Durham cattle, were introduced many years since by the president of this society; and it is mainly through the influence of this and similar associations, that the beautiful McKay, Berkshire, China, and Byfield pigs, have in that state mostly superseded the long-nosed, impossible-to-fat swine that formerly devoured the corn of the bay state. This improvement in pigs alone was many years since, by one of the most extensive dealers in pork in Massachusetts, estimated at more than a hundred thousand dollars.

It gives us pleasure to state that the bill to continue the appropriations of the state for such purposes was sustained by a vote of more than twenty to one. The course of the Massachusetts legislature is one honorable to their patriotism, and a proof of their intelligence. Their bounty on wheat, will cause the production of a handsome crop, we have not a doubt; we only regret that such quantities of wheat have been sent to eastern farmers, under names to which it has not the slightest pretension. The "staff of life" should not be subjected to such petty speculations and deceptions.

FIBROUS-LEAVED PLANTS, AND THE MODE OF PREPARING THE FIBRES.

To the Editor of the Farmers' Register.

Washington, D. C., 2d July, 1838.

Dear Sir—You may have perceived in the newspapers, that on the 12th June, the bill to encourage the introduction and cultivation of Tropical Plants, was passed in the senate by a vote of 26 to 11; the majority including the names of the most distinguished senators, of all parties, in their seats on that occasion. You may also have seen that on the 28th ult., the committee on agriculture of the house of representatives re-reported the same senate bill without amendment—a measure upon which they unanimously agreed two weeks before. The committee on agriculture has but two bills to be acted on—viz: said senate bill, and the bill to establish an agricultural department in the Patent Office, and although that committee, ever since the establishment of the government has not ever asked its right to be heard by congress, it has not this session been able to obtain a single hour for the consideration of its humble bills.

On Saturday last, Gen. Jesup spent an hour in the committee room, in the examination of the specimens of foliaceous fibres of fibrous-leaved plants adapted to both the *arid* and the *humid* surfaces of Tropical Florida. He stated that all Southern Florida from 28° N. L. to Cape Sable, had now been explored by himself, officers, and soldiers, and that they still re-affirm the fact, that for our actual staples the whole district is not worth the expense of surveying; that my suggestion alone can render valuable the country hitherto considered uninhabitable and uncultivable, and that the government ought to grant the whole territory below 28° to actual settlers and cultivators on the conditions of the aforesaid senate bill. That bill you will see merely admits the prospective sale of one or more sections, not exceeding thirty-six in all, for the most valuable considerations ever offered to any government or people for the actual settlement and cultivation in valuable plants, within eight years, in a district officially affirmed to be uninhabitable and uncultivable, unworthy of the expense of a survey, or even of the cost of medicines requisite to conquer it. Although my heart sickens with hope deferred, after eleven years' laborious absence from my family, yet I shall still have some consolation, provided public attention will thus be excited towards the propagation of our *indigenous fibrous-leaved plants alone*. The Hon. H. Wise thinks that he recognizes, in the Agave Virginica of my plates, a familiar plant in his district, there called silk grass, of which slips of the leaves have long been used for economical purposes—especially for straps to suspend hams, &c., without suspecting that they contained strong glossy white fibres, which may be profitably extracted for sale or manufacture. The economical uses of the Yucca filamentosa or bear-grass, i. e. of the unscraped leaves or slips of leaves, have been known from time immemorial, in all our southern and south-western states. The Hon. R. Hawes, of Kentucky, informed me that the name of Bear-grass Creek, in his state, was taken from the abundance of the Yucca filamentosa on its borders. Nuttal tells us that it inhabits the banks of the Missouri, from the confluence of the river Platte, to the mountains—and hence at one point near the junction of White-earth river, it must extend to 48° N. latitude. Mr. Catlin, the painter, also says he met it abundantly during his travels in the far north-west.

On the other side this plant is becoming acclimated in our middle and north-eastern states. In 1831-2, I found it during the winter in open gardens around New York, and then predicted to the committee on agriculture that it would become a superior substitute for flax on the steril soils of the adjoining states. The Yucca filamentosa was there introduced from the southern states as a merely ornamental plant of the gardens of the northern states, where they have accidentally discovered that it propagates itself, and passes through their bleak winters without injury. Even in the garden of David Thomas, Cayuga county, New York, the bear-grass grows through the coldest seasons, without any prejudice to its green-living leaves; and in Princeton, N. J. in January last, several leaves were cut, and dressed in a common flax mill—and the fibres sent to this room, where they are now before me. They, however, still retain a greenish color, and are comparatively feeble, because they were *bruised* instead of being *scraped*.

I hence trust that you will consider the subject of fibrous-leaved plants sufficiently important to your readers, to justify the publication in your periodical of the last twenty-two pages of the report of the committee on agriculture of the house of representatives. Should you coincide in my opinions of their immense value to all the poorest soils of our southern states, you will, doubtless, be pleased to request from your readers, information concerning the localities and quantities of each indigenous species within their respective districts, with such additional observations as they will probably be equally glad to communicate. Should your periodical thus make public the location of any considerable quantity of our indigenous Yucca or of our indigenous Agave; it will, no doubt, excite our ingenious machinists to transport themselves to the spot, and invent labor-saving machinery suitably modified to scrape the leaves of each species. Although not born in New England, I had Yankee blood enough to invent, many years ago, two forms of machinery adapted to separate the foliaceous fibres from the green living leaves of the Sisal hemp agave, and of all analogous plants. Of the simplest form, an idea may be obtained by comparing it to a common grindstone moved by a treadle with the foot. A wooden wheel of six feet diameter, when once set in motion would have its velocity so aided by its momentum, that a single revolution would scrape the one side of any leaf or leaves applied to its circumference. For the leaves of the Sisal hemp, at an average of four to five feet, a curve of one-fourth of the wheel would suffice.

The curved compresser would be retained near the surface of the wheel by spiral or other spines. The perphery of the wheel would be crossed by straps of hard wood, or of iron, with blunt edges, for scrapers. The wheel once in motion from the foot of the laborer, he would take the but-end of a leaf in his hand, and insert the point between the compresser and the wheel, which would thus carry down the leaf as far as the but, still retained by the hand. One-fourth of a revolution would thus be spent in simply carrying down the leaf between the surface of the compresser and of the wheel; but the leaf then being held fast by the hand, the other three-fourths of the revolution would be a scraping process alone. As the fibres thus exposed would not then offer any resistance to being withdrawn, the leaves are then pulled out, and the unscraped side is next inserted; and the foliaceous fibres will thus be separated on both sides to a short distance from the but-ends. Even that may be advantageously left as a bond of union to the mass of fibres, and thus save the labor of tying them into knots. But as our countrymen will not be satisfied with the labor saved by such a machine, I invented another to be moved by portable horse power. This will consist of two pairs of cylinders, to be called feeding cylinders and scraping cylinders. The upper cylinders to be smooth and to move slowly; the lower cylinders to be grooved and to move swiftly, and the leaf or leaves to be inserted perpendicularly into the feeding cylinders, and to be thus conveyed perperdicularly through the scraping cylinders. Hence, both sides of the leaves will be scraped at the same time; and the offal will fall to the ground without being entangled in the fibres. With this machine, however, there will also remain unscraped a portion of the but-ends; but with me it is a question whether it will not be more advantageous than injurious, to let it remain as a bond of union to these long straight parallel fibres.

I enter into these details to save a world of speculation and of labor to other inventors, and cultivators. Their first impulse always is to seek some analogy with common flax and hemp. They will talk about rotting and breaking these *green-living leaves*, as they have been accustomed to treat the dry hard barks, from which they extract flax and hemp. After having gone through the whole routine of inventions and experiments, they will, however, all finally arrive at the conviction that simple *scraping* only, is the cheapest, the easiest, the speediest and the healthiest of all possible processes to obtain foliaceous fibres from the green-living leaves of fibrous-leaved plants.

I have the honor to be, sir, very respectfully, your obedient servant. H. PERRINE.

[The bill granting to Dr. Perrine 23,000 acres of land in Florida, for the purpose stated in several foregoing publications, finally passed on the last evening of the session of Congress just closed.—ED. FAR. REG.]

PREMIUMS AWARDED BY THE AGRICULTURAL SOCIETY OF CHARLOTTE.

[Published by request of the Society.]

At the annual exhibition of cattle and other stock, belonging to the members of the Agricultural Society of Charlotte county, held at the Courthouse of said county on the 12th day of October, 1837—premiums were awarded to the gentlemen whose names are hereto assigned.

To Mr. John Marshall, for the best milch cow, by Col. Marshall's Pompey, out of a Devonshire cow.

To Mr. John Marshall, for the best heifer under two years old, by Cardwell's Durham, out of the Pompey cow.

To Mr. John Marshall, for the best brood mare, Whittleberry, by Roanoke, out of Wakefield, by Sir Hal.

To Capt. Henry A. Watkins, for the best yoke oxen.

Do. do. do. do. mule.

To Mr. Henry Carrington, for the best beef.

Do. do. do. do. do. heifer under three and over two years old, by Col. Richardson's bull Powell.

To Mr. Henry Carrington, for the best filly one year old, by imported Claret, out of Blanch, by Gascoigne, g. d. Miss Ryland.

To Mr. R. I. Gaines, for the best bull.

Do. do. do. do. Saxon ram.

Maj. William Gaines, for the best two-year old colt, by Carolinian.

Mr. Thomas F. Merryman, for the best foal, by imported Emancipation.

To Mr. Wyatt Cardwell, for the best saddle horse, out of Amy, by Gracchus, by Gascoigne.

Communicated by order of the Society,
HENRY CARRINGTON, *Sec'ry.*

From the Cultivator.

MINERAL MANURES.

Although there is much to please and interest the mind in practical farming, yet, devoid and apart from the theory, it is little else than a routine, suited to the capacity and ambition of uncultivated minds. An active and enlightened mind seeks to understand the cause and effect—to apply the sciences; in short, it is restive, until the queries embraced in agriculture, are disposed of and determined upon sound philosophical principles. 'Tis this constitutes theory; and 'tis this theory, that unfolds a world of beauties to the scientific agriculturist, of which the mere prejudiced practical farmer, the mere tyro and novitiate, must remain ignorant, and that too, of the highest branch of the profession which he follows.

The improvement which has been effected within the last twenty years in several of the eastern counties of Pennsylvania, (and especially in Chester,) is almost incredible. And the whole is mainly attributed to a regular and judicious use of lime as a manure. To me, it has been matter of astonishment, to find this inestimable restorative meet with so little favor in the minds of the conductor and correspondents of the Cultivator. My farm is situated in a district of secondary formation, and the soil is principally calcareous, yet I have seen the most surprising beneficial effects attending the free use of lime and plaster; the latter apparently reacting on the former, and consequently, the greatest benefit is derived by using them together. The crops, not only on my own farm, but on others in this vicinity, have been doubled by a free use of mineral manures. When a farm has been improved so as to produce heavy crops, there will be such a corresponding increase in the quantity of stable manure as to insure its future fertility. I look upon the immense beds of limestone in this region as an inexhaustible store designed by the wise Governor of the world to keep up the strength of the land, in all time to come. I regard the limestone of Pennsylvania as a mineral, which will confer more real benefit on posterity than any of her other mineral treasures. The aid which it promises to contribute to the support and improvement of her agriculture cannot be easily overrated. Some idea may be formed of the estimation in which lime is held here as a manure, by the fact, that farmers come from 25 to 30 miles, i. e. from Maryland and the poor district of primitive formation in the southern part of Chester county, bordering on the Maryland line, to my limekiln and others in the neighborhood; the lime costing those farmers 25 cents per bushel when delivered. To the farmers in that quarter, lime is the "anchor of hope;" there it has already made the barren and desert place glad, and is fast putting a new and improved face upon the country. The farmers, even there, with this far fetched means of improving their land, prefer bettering their condition by liming near a good market, rather than migrate to the exuberant soil, and realize the utopian dreams and fairy tales of the "far west."

On part of my farm, 300 bushels of lime per acre have been applied within 30 years, at the rate of about 100 bushels per acre at a dressing, and always put on fresh, and slaked, then immediately spread. I am not inclined to believe that lime should become carbonated before it is applied. I adopt Sir Humphrey Davy for my prototype, in every case involving agricultural chemistry. I shall be encouraged so to do, until some modern wiseacre can clearly demonstrate that Sir H. is wrong. Doubtful points in Davy's theory have become demonstrable truths with me, after being aided and enlightened by the lamp of experience. Lime, in its fresh caustic state, only while an alkali, acts as a decomposing agent in the soil; rendering vegetable substances soluble—but when a mild carbonate, it operates only like marl, in improving the texture of the soil, according to Davy, whose authority is unquestionable, and the theory, at all events, may fairly challenge contradiction; hence the advantage of applyng lime, like stable manure, in a fresh state.

With regard to the theory, or the manner, in which gypsum operates on vegetation, an accidental circumstance which occurred in my practice or under my own eye, goes further to establish the truth in my mind, than all the ink which has been spilled on the subject; even the adopted theory of Prof. Low and British Husbandry to the contrary notwithstanding. In April, 1832, I sowed half a bushel of plaster on a small piece of land in the middle of a wheat field, for experiment in order to ascertain whether the plaster would have the slightest effect even of changing the color of the wheat. The result answered my expectations; there was not a shade of change in the color of the wheat in the future stages of its growth. In autumn following, the same field was again ploughed for wheat and the plaster course turned down, the field was deeply ploughed, say 7 or 8 inches—the spring following the field was sown with clover seed; the secret then was speedily developed; when the wheat was cut in harvest the growth of clover on that same land which had been sown with plaster, was so luxuriant as to interfere with the cradle in cutting the wheat. —Soon after harvest, the clover on the said land flowered, and a heavy swath might have been mown on it in September following. The adjacent parts of the field, with the same soil and culture, exhibited a sickly contrast. In the autumn of 1833, the clover on said land was trodden down by stock, returning manure to the soil, and by that means the plaster indirectly prepared the ground for a sure crop of wheat. This one single and simple fact serves to overthrow the theory that plaster must be sown on the plants, to be absorbed through the pores of the leaves—attract moisture from the atmosphere, &c. This mooted point I consider settled, and the soil and roots made the laboratory instead of the leaves and the atmosphere.

Although my agricultural career has been only short, yet the great object, improvement, has been ardently and zealously pursued—sufficiently, indeed, to create a most utter and implacable abhorrence against all vague and unfounded theory, which is the bane of the agricultural press. The mere conjecture of a writer, if in error, will do no harm; but 'tis the positive declaratory assertions, where wrong, that do mischief, inasmuch as many believe and adopt what they read.

Quere. Why is it that lime and plaster act much more efficiently when both are applied to the soil, since the base of both is lime?

WM. PENN KINSER.

Pequea, Lan. Co., Pa., April 15, 1838.

USE OF LIME IN NEW HAMPSHIRE.

One of the shakers recently told me, they had been in the habit of buying the best of Thomaston Lime, which with transportations cost them at least $3 a cask; of breaking and slaking it, and mixing it with mud collected from bog-holes or turfs from the sides of the highways, in proportion of four or five casks to a hundred common ox loads; and after due fermentation and mixture, they have found this composition not less valuable than an equal quantity of the best of stable manure. If the above remarks are correct, and no doubt they are, as I find them corroborated by various writers on this subject, it is an easy and cheap method of obtaining manure and well adapted for top-dressing.

The Hon. John Wells of Boston, who has made several experiments with lime in the preparation of compost manure for a top-dressing, recommends that it be prepared by first placing a layer of mud or loam, as the case may be, then a layer of unslaked lime, and so continue until the materials are used up; and in twelve or fourteen days, shovel it over and it will be fit for use. From what I am able to gather from this gentleman's experiments, he made use of lime in proportion, of about one cask of Thomaston lime, to five loads of loam or mud, and that he annually, for more than twenty years made use of lime, 'for agricultural purposes to the extent of more than one hundred casks.' He further says:—'To my surprise I found the effect produced to be equal to what is usual from common compost manure!' Lime as a top-dressing on a wheat crop is undoubtedly valuable on many kinds of soil, especially where there is a deficiency of calcareous matter.

Benj. Cutter, esq., informs me that he has made use of lime at the rate of twenty bushels or more to the acre, as a top-dressing, by sowing it on in a fine pulverized state, when the wheat was a few inches high, and considered himself well remunerated in the wheat crop. The Hon. Levi Fisk, observed to me, that he used two tierces of Thomaston lime last spring by sowing it on nearly two acres of wheat, leaving a small piece in the same field unsown, and is confident he realized twenty-five per cent. more wheat in consequence of the lime. The above and other similar experiments, are conclusive evidence in my mind, of the importance and value of lime as a manure.—*Conant's Cheshire Address.*

THE COLLEGES OF VIRGINIA CONSIDERED AS WORKS OF "INTERNAL IMPROVEMENT." WILLIAM AND MARY COLLEGE.

The colleges and schools of a country are among the most important and valuable means, as well as results, of its general improvement. Nor is the improvement thus reached merely intellectual and moral. The physical improvement of the country, the enriching of its lands, the increase of its agricultural products, and the amount of pecuniary profit to the cultivators, all are essentially aided by providing, and properly using the facilities for education afforded by schools and colleges; though the design and direct operation of these institutions should be confined exclusively to literary and scientific instruction, and without any view to the physical or economical improvement of the country. And the effects so produced, in their turn become causes; and help, in an important degree, to sustain literary and scientific institutions. In strict accordance with these views are found the practical results, wherever they have been permitted to be produced by the action of causes continued sufficiently long, and with sufficient intensity. In the country which surrounds and sustains Hampden-Sidney College, there is found a population, whose intellectual and moral worth, economical and industrious habits, and whose marked success as farmers and men of business, prove beyond doubt or cavil, the great profits, individual and pecuniary as well as general and national, which the people have derived from their liberal and long-continued support of that college. We are less acquainted with Washington College; but have been informed, and believe, that similar and equal effects have there been produced by the operation of similar causes. Randolph-Macon College is yet too young an institution to have given such manifest evidences of its value as a work of "internal improvement;" but it is doubtless annually producing these valuable results; and requires only as much time, with equal good management, to exhibit as strong evidences of value.

This manner of viewing the subject will prevent any objection to the propriety of treating of our colleges in this journal, of which the second object is to sustain and aid all public works for the improvement of

Virginia; nor will the subject be deemed unconnected with the first or principal object of the Farmers' Register, which is especially agricultural improvement.

The colleges referred to above, highly beneficial as they are to the commonwealth, as well as to the people more especially interested in them, are local institutions—principally sustained by, and in return sustaining and elevating, the surrounding and adjacent, though an extended region of country. And it is because of this local action, and yet very general operation within such limits, that the improvement made in the people and in the country can be so easily traced, and so clearly exhibited and proved. The University of Virginia, from its rich endowment, its identification with national interests, and its other peculiar and great advantages, is diffusing knowledge and improvement to every part of the state, and to far remote states; and the benefits thus produced are not the less certain and important, because, from their wide diffusion, they are less susceptible of being accurately estimated, and duly appreciated.

William and Mary College at present partakes of both these characters. Formerly it was the state or principal institution of Virginia, and even of all the southern and western states then in being. Yet, in its former days of prosperity, (as they were then deemed,) and when receiving students annually from every region of Virginia, and some from perhaps five or six other states, still the number of students in the scientific classes ranged between 60 and 90, and rarely, if ever, exceeded the latter number. The boys in the school for Latin and Greek, are not counted under the name of "students," in this institution, and are not so included in these or any of the following remarks; though all such boys, in the middle and higher classes, *are* so counted in most other colleges; and thereby serve to swell their apparent numbers, and, by the comparison, to make the number of students of William and Mary appear fewer in comparison. In making comparisons, this difference should not be overlooked.

From that condition, William and Mary was struck down to the lowest state of depression, first by the war, which brought an invading enemy into its near neighborhood, and for two years caused frequent calls upon every student of military age for military service in the field. Under such circumstances, the continuance of regular or even profitable study and collegiate duties, was rendered impossible; and parents either kept their sons at home, or sent them to distant colleges, which were free from such continual alarms of invasion, or marauding incursions from the British fleets. There were afterwards transient returns of prosperity to the college, but of no long continuance; as other and different blows, not necessary here to particularize, fell upon it in rapid succession, and served to impair its interests, and to thin its ranks. These changes and fluctuations will be passed over, to the session of 1833-4, when the institution seemed to be so nearly prostrate, that the loss of any one valuable professor was feared as a blow too heavy to be then borne; and an evil impossible to repair, owing to the small remaining inducements to attract or retain able professors. That session, the whole number of students amounted to no more than seventeen. Not long before, more than two years had passed without a quorum of the board of visiters being got together, and of course without a meeting or any action of that body—those members who were present, and ready to act, having been rendered useless by the non-attendance of others.

During that time the important professorship of mathematics remained vacant; and though its duties were performed by the extra service of another professor, still the vacancy and its cause could not but greatly impair the public confidence in the management and usefulness of the institution. This neglect of the visitors to attend, and act in convocation, was the great cause, out of which grew all the minor and auxiliary causes, of the decline and threatened extinction of the college. In July 1834, a meeting of a bare quorum (a majority of the visitors, as required by the charter,) was, with difficulty, obtained; and a system of reform and improvement was then begun, which has been zealously continued to this time, and which has produced the most remarkable and manifest improvement in the number of students, and in the value of the course of instruction. So far as the increase of number of students may serve to indicate increase of prosperity and value of the college, these will strongly enough appear in the following statement of the numbers for the five last courses.

In session of	1833-4,	there were	17 students.
	1834-5,		48
	1835-6,		69
	1836-7,		113
	1837-8,		112.

When the universal pecuniary difficulties and losses of the last fifteen months are considered, the last number, though a little less in amount than that of the year preceding, is, in fact, a stronger evidence of increased public confidence in the institution, than the previous rate of progressive increase of numbers. And this high eminence will be justly deemed the more remarkable, when considered in comparison with the previous and long continued depression—in comparison with the former state, when William and Mary had not a rival in this or half a dozen adjacent states—and considering that now there are three other colleges deserving and drawing their shares of students, and still more the University of Virginia, in a state of high prosperity, and having from 200 to 240 students during each of the last three years.

While we wish the greatest possible success to all our institutions of education and learning, it may be permitted to us, without being obnoxious to the charge of being sectional in feeling, or wanting in good will to others, to set forth more especially the claims of William and Mary College as the now local institution of the tide-water region, in addition to its other and strong claims of a general nature. It has ceased to be the principal college of this and other states, not because of diminished value of its instruction (for that has been greatly increased—) but because of the establishment of sundry other institutions, by public or private endowment, which circumstance has recently changed the aspect in which each one must be now considered. William and Mary, as much as any other college, deserves the support of the whole country; and in consideration of its mild and delightful climate, perfect healthiness during the whole time of the course, *and peculiar suitableness to the constitutions of southern young men*, there are strong reasons for its being preferred, for all such pupils, to any colleges of equal scientific grade situated in more northern or elevated regions, and in a more rigorous climate. It is too true that this comparison is seldom made, and that danger to the health of southern boys sent to bear northern winters is scarcely thought of. Even the people of our low country are themselves accustomed to acquiesce in the general understanding that an unhealthy region is one where bilious or autumnal diseases only are to be feared; and that if these are absent, or very rare, a country is healthy, no matter how much its people are scourged by catarrhs, consumptions, rheumatisms, and pleurisies. By one or more of these latter diseases, the constitution of many a southern youth has been seriously injured, or destroyed, at northern seminaries; and even if he escapes all these, he is rendered, by a northern residence, unfit to revisit his southern home, in autumn, without danger; and if, to avoid that danger, he remains away for years together, he acquires a northern constitution, and is as unfit as if born in the north, to live at his proper and intended future home.

But putting aside this important consideration, and viewing William and Mary merely as a local institution, the tide-water region alone can and ought to furnish it with enough students to triple its present number. And when we say *ought*, it is not meant that the obligation should extend further than would be limited, on full knowledge of the circumstances, by the private and individual interests of the parents, not only as parents, but as residents and property-holders of the low country. It is not their general interest to prefer this college unless it deserves a preference for the value of its instruction and training of youth, and on the grounds of the moderate rate of price at which the benefits are to be obtained.

The course of classical instruction, or the school for Latin and Greek, is very defective when compared to most other colleges of high rank. Until the last session, it was a grammar-school, upon the ordinary footing of common schools for teaching Latin and Greek; and was the more liable to objection because of its connexion with a scientific institution of high order. Better instruction in the higher classical studies was in part provided for, a year ago: and by another year, it is hoped and expected that William and Mary will exchange the grammar-school for a system of classical instruction suited to more advanced pupils and regular students. When this is properly done, there may be justly awarded to the whole institution, the high commendation which all the other departments now well deserve. The professorships are well filled; the course of instruction is excellent, and is designed to be of practical application, no less than it is of high scientific character. The government and discipline of the students is parental, though sufficiently strict; and, while no known offender is permitted to pass unpunished by the laws of the institution, still the means to govern, and the prevention of offences, are more generally and effectually found in a reliance on and appeal to the sense of honor and propriety of the young men; who are reminded at every step, and in every hour, by the general purport of their training and association, that the first duty of a student is to preserve, in every particular, the character of a *gentleman*, and man of honor and truth. This most powerful aid to the statute book, (and without which mere enactments and punishments are of little avail,) has been strengthened and brought admirably into operation by the tact of the present faculty of the college, and by the respect and regard of the students which the professors fortunately possess, and the consequent influence which they can exercise. And this mode of governing, by appealing to the best feelings, instead of merely punishing the fruits of the worst, is further strengthened by the tone of the private society in which students here may freely mingle, and are received with welcome, and which, while it softens, refines and cultivates manners, and guards against vicious pleasures by substituting innocent relaxation and amusement, also, by approbation or censure, increases the inducement to do good, and to refrain from evil. Much good has always been done by the society of the inhabitants of Williamsburg to the students of William and Mary; and, it must be confessed, also some harm—and in former times *much* harm. But the evils of this kind, which have existed, have been clearly seen, and are now guarded against, by example and precept, of all belonging to the best society. And, though imperfections and evils will always exist to some extent, it may now be safely asserted, that the influence of society in this place was never so beneficially exercised, as now; and its influence is, in the general, decidedly and greatly beneficial to the students. Either the total exclusion from private association with well-bred people (and especially from female society,) or the mingling with the fashionable and often debauched society of large cities, and sharing in their vicious pleasures, are conditions very different from that of the students of this college, and the operation of either of which is always greatly to be feared.

The result of all the measures of reform adopted by the board of visitors, and admirably executed by the faculty, and of the influences thereby and otherwise produced, has been the attainment of a degree of moral and intellectual improvement in the students in general, for the last two years, and more especially during the course just ended, which furnishes to the friends of the institution very far more cause for congratulation, and ground for auguring still increasing prosperity and success, than merely the rapid and continued increase of students. During the last course, the conduct of all but a very few of the young men, has been throughout orderly and correct, and gentlemanly in all respects; and when taken altogether, the abatement necessary to make for the few of other habits, will not prevent the general conduct of the students being considered in a remarkable degree free from the offences of disorder and vicious habits so usual in colleges. Far otherwise was the state of things in former times; and much prejudice still remains against this college in the minds of many who know and believe nothing of the true condition and high value of this institution, and who, as erroneously, in regard to this and to all other colleges, charge the vicious propensities of every student, which are generally caused by the improper indulgence of his own father, to the college which has in vain struggled to prevent the evils thus caused by more powerful counteracting influences. There is no cause to fear detriment to the virtues or good habits of any youth who may be now sent to this college, unless caused by the fault either of his incurable evil propensities, or otherwise, as is most usual, by the error of his previous training and the continued improper indulgence of his parent. Almost every case of a student proving either extravagant in expenditure, dissipated, or vicious, is caused by his being furnished with too much money. If a youth receives even $20 more than a sufficiently liberal allowance, the excess must do injury to his habits; and when that excess is carried to $300, merely because the father is rich enough to afford the expense, he almost invariably and greatly injures, and perhaps ruins his son, by such unjustifiable indulgence. The money thus annually wasted at most colleges of high grade, to the injury of all parties, is usually as large as all required for the necessary and proper expenses. The parent, who, in spite of all warning from the college authorities, will commit this common error, has no right to charge the vices or idleness of his son to any other than himself. The necessary collegiate expenses of a junior student at William and Mary College, for professors' and other college fees, (and as many as can be usefully paid,) board, books, and every other necessary expense, amount to $228, if the student boards in college, or $248, if in a private family. Add to this what is safe and proper for pocket-money, (and that certainly ought not to exceed $50, for a young and new student,) and every expense for the junior course is provided for, except the purchase of clothing, and that is not a collegiate expense. The *necessary* college expenses of the senior course are still less than those of the first year. Few boys, just freed from the restrictions of a school, or their fathers' guidance, can be safely trusted at one time with even $50, to be retained and used as pocket money for the coming time of nine months. To their inexperience it would seem a sum so large that they will scarcely get through it; and in a month, perhaps, they find that it has slipped through their fingers, and left a newly created appetite for ten times as much. In such cases, it is the father, much more than the son, who is to be blamed. What then is to be said of the parent, who, merely because he is rich and purse-proud, sends far from home an inexperienced youth, totally unused to the ways of the world, with several hundred dollars in hand more than needed for early expenses? It is almost a miracle when it does not do great injury to the student; and often it corrupts and destroys the man for ever. The sons of the richest parents are generally the least worthy or profitable students—and often, their attendance is a loss, even in a pecuniary point of view, to the college which they enter.

The propensity of students to contract debts is encouraged, first, by the extravagance engendered by parental indulgence, in giving too much money, and next, by the seductions and enticements of the rapacious harpies and sharpers among the shopkeepers, tavern-keepers, and others, some of whom are as sure to be found about every college, as vultures will be seen flocking to a carcass. An excellent regulation of the visitors of this college, which has now been two years in operation, has already done much good in restraining this abuse; and it would have been effectual, if parents had properly seconded and sustained the law, and the authorities of the college. At the last session of the legislature a general law was passed for this purpose; and it is hoped that this infamous practice will be more effectually checked. It is a fraud of the worst kind; for it preys upon the sufferers' precious time, morals, and future prospects of usefulness and happiness, as well as upon their money, which alone is the object sought by these tempters and destroyers of heedless youths.

The regular course of study, here necessary to obtain the degree of A. B. (Bachelor of Arts,) is of two years' continuance. This does not include instruction in the Latin and Greek languages; which, it is presumed that the student has acquired at school, more cheaply, and far more profitably, than he would at college. To obtain the degree of A. M. (Master of Arts,) a more extended course of study, and higher attainments, both classical and scientific, are requisite; and to this end, profitable employment is furnished for one or for two years longer. Thus, although the scientific course proper of the college may be and ought to be passed through, and its honors obtained, by every properly prepared and diligent student, in two years, (which is a great advantage, and economy of time and money to those who can better prepare at lower schools,) still, if such classical preparation as makes part of the regular course at most other colleges, be added to the account, it would add one or two years to the beginning of this; and for the course necessary for A. M. one or two years more must be added at the end. Thus, the course of study may be two years, or it may be four, or even six, and all well and fully occupied, according to the circumstances and attainments of the student. The diplomas are conferred only for a proper degree of proficiency, to be shown upon strict examination; and in no case upon the ground of having merely passed through the whole time of the college course, and paid all the fees; which will entitle every student at most or all northern colleges to a diploma, as a matter of course. Honors thus conferred, no matter how exalted in reputation and merit may be the college conferring them, are in most cases awarded without being deserved; and any institution thus granting them, is guilty of a despicable fraud upon the public. The same and only correct and *honest* mode of conferring honors and diplomas as has always been the practice at William and Mary, that is, upon full examination and evidence of proficiency, has likewise been pursued at the University of Virginia. And consequently, a student who would not even dare to ask for a degree at either of these institutions, from being conscious of not deserving it, would receive it, as a matter of course, if belonging to a northern college of the highest rank and character. Upon this deceptious system, the whole senior class graduates; or it is a very rare and remarkable occurrence if any one of the class should be refused his degree. Therefore, if rightly viewed, the large number of degrees annually conferred, would show their very small average value; and every one, of the small comparative number, where they are conferred on proficiency exhibited, ought to be so much the more highly prized.

We have just returned from a session of four days of the Board of Visitors, and attendance on and observation of the closing scenes of the last course of William and Mary College. The evidences of the very orderly and correct deportment of the students generally, the rareness of the cases of opposite conduct, and the fruits of labor and profitable instruction shown in that portion of them who earned the honors of the college, were all highly gratifying. These extended remarks show our own individual and entire concurrence in the unanimous expression of approbation of the Board of Visitors, as copied in the proceedings below. And we assert, without hesitation, that if the people of lower Virginia alone who now send their sons to northern colleges would give their support instead to William and Mary, the gain would be not only great and important to that institution, but far more so to the students and to their parents, and to the commonwealth of Virginia. We would never send a son, or advise other parents to do so, to an inferior school, because it was in Virginia. But if equal or superior advantages are available at home, as is certainly the case, then both patriotism and economy ought to concur in causing the institutions of learning in Virginia and the south, to be encouraged, rather than those in the northern states.

ED. FAR. REG.

PUBLIC EXERCISES OF WILLIAM AND MARY COLLEGE, JULY 4TH, 1838.

The public exercises at the close of the late session in this institution, took place on the 4th inst., as usual.

At 10 o'clock, A. M., the Visitors, Professors and Students, attended by the Volunteer Companies of the place, commanded by Captains Armistead and Durfey, (who politely tendered their services on the occasion,) moved in procession from the College to the Church, where the exercises were commenced by a prayer from the Right Rev. Bishop Meade. Then, after fine and appropriate music, for which the audience were indebted to the kindness of the ladies, the exhibition by the graduates was for a moment suspended, while the President read the following resolution of the Board of Visitors:

"Resolved, unanimously, That the Visitors of Willam and Mary College, have learned with undissembled satisfaction of the flourishing condition of the College, and of the orderly and correct deportment of the students during the session which has to-day terminated: and that the President be requested publicly to express in the Church, to the young gentlemen of the institution, the warm and decided approval felt by the Visitors of their exemplary conduct."

After which the following Orations were delivered:

1. Oration on the formation of National Character, by Samuel S. Henley, A. B. of King & Queen.
2. Oration on the rise and prosperity of the United States, by Tho's. B. Donnelly, A. B. of Williamsburg.
3. Oration on Internal Improvement and its effects on the condition of Virginia, by William L. Henley, L. B. of James City.
4. Oration on the influence of Literature on Society and Government, by Herbert A. Claiborne, A. B. of Richmond.
5. Oration on the influence of William & Mary College on the Literary, Moral and Political condition of this country, by James A. Clopton, A. B. of New Kent.
6. Oration on the inefficiency of Governments to conduce to their proper end, with war as their prevailing spirit, by Gawin L. C. Salter, L. B. of York.
7. Valedictory to the Members of the Franklin Society, by Robert Tyler of Williamsburg.

The President then proceeded to confer the Degree of Bachelor of Arts on the following twelve young gentlemen of the senior classes:

Herbert A. Claiborne of the city of Richmond.
James A. Clopton of New Kent.
Benjamin F. Dew of King & Queen.
Elias Dodson of Halifax.
Thomas B. Donnelly of Williamsburg.
John Finney, of Powhatan.
John M. Galt of Williamsburg.
Edward Gresham of King and Queen.
Samuel S. Henley of King and Queen.
Archibald C. Peachy of Williamsburg.
Robert G. Scott of the city of Richmond.
John O. Steger of Amelia.

And the degree of Bachelor of Law upon the following:

William L. Henley of James City.
Gawin L. C. Salter of York.

The President then bestowed upon the following thirty-nine young gentlemen, of the junior classes, certificates, under the college seal, of proficiency and good conduct.

William Blankenship of Chesterfield: National Law—Rhetoric, Logic and Ethics—Chemistry—the Junior Mathematical Course—History.

John B. Cary of Hampton: Natural Philosophy—Mathematics—Political Economy—National Law—Rhetoric, Logic and Ethics—Chemistry—Civil Engineeriug.

James L. Clarke of Gloucester: National Law—Rhetoric, Logic and Ethics—Chemistry—the Junior Mathematical Course.

Nathaniel C. Cocke, of Prince George: National Law—Rhetoric, Logic and Ethics—Chemistry—the Junior Mathematical Course—History.

John A. Coke of Williamsburg: Natural Philosophy—Political Economy—Metaphysics—National Law—History.

William Cole of Prince George: National Law—Chemistry—History.

William W. Crump of the City of Richmond: Political Economy—National Law—Rhetoric, Logic and Ethics—Chemistry—History.

Edwin H. Edmunds of Brunswick: Chemistry—History—Junior Mathematical Course.

William H. Fitzhugh of Prince William: National Law—Rhetoric, Logic and Ethics—Chemistry—Junior Mathematical Course—History.

Benjamin F. Garrett of Williamsburg: National Law—Rhetoric, Logic and Ethics—Chemistry—History.

John J. Gravatt of Caroline: Political Economy—Metaphysics—National Law—Rhetoric, Logic and Ethics—History.

William H. Gwathmey of King William: National Law—Rhetoric, Logic and Ethics—History—Chemistry.

Henry Harrison of Charles City: Mathematics—Metaphysics—National Law—Rhetoric, Logic and Ethics—Chemistry.

Jas. B. Jones of Chesterfield: National Law—Rhetoric, Logic and Ethics—Chemistry—Junior Mathematical Course—History.

Alexander Jones of Chesterfield: National Law—Rhetoric, Logic and Ethics—Chemistry—Junior Mathematical Course—History.

Warner T. Jones of Gloucester: Natural Philosophy.

William McGowan of Petersburg: Natural Philosophy—Political Economy—Junior Mathematical Course—Civil Engineering.

Nicholas Mills of the City of Richmond: Natural Philosophy—Rhetoric, Logic and Ethics—Civil Engineering.

Charles P. Moncure of the City of Richmond: Metaphysics—National Law.

Thos. B. Montague of Gloucester: Rhetoric, Logic and Ethics—History—Chemistry.

Chas. W. Montague of Gloucester: Rhetoric, Logic and Ethics—Junior Mathematical Course—Chemistry—History.

Woodson C. Moody of Williamsburg: National Law.

Wilson N. Nicholas of the City of Richmond: Natural Philosophy—Political Economy—Metaphysics—Rhetoric, Logic and Ethics—Chemistry—History.

George U. Nottingham of Northampton: Junior Mathematical Course.

William M. Overton of Lunenburg: Mathematics—National Law—History—Civil Engineering.

William R. Pierce of Williamsburg: Chemistry.

William P. Richardson of New Kent: National Law—Rhetoric, Logic and Ethics—Chemistry—Junior Mathematical Course.

Powhatan Robertson of the City of Richmond: Natural Philosophy—Chemistry.

Moore Robinson of the City of Richmond: National Law—Rhetoric, Logic and Ethics—Chemistry—Junior Mathematical Course—History.

John W. Rochelle of Southampton: Chemistry and Civil Engineering.

Julian C. Ruffin of Petersburg: National Law—Rhetoric, Logic and Ethics—Chemistry—Junior Mathematical Course—History.

Peter S. Smith of Nottoway: National Law—Rhetoric, Logic and Ethics—History.

William M. Sutton of Hanover: Political Economy—Metaphysics—National Law—Rhetoric, Logic and Ethics—Chemistry.

William B. Taylor of Prince George: Junior Mathematical Course—Chemistry—Civil Engineering.

William A. Thom of Culpeper: Rhetoric, Logic and Ethics—Chemistry—Junior Mathematical Course—History.

William Waller of Williamsburg: National Law—Chemistry.

George Wingfield of Norfolk: Natural Philosophy—Junior Mathematical Course—Civil Engineering.

John J. Wright of Essex: Junior Mathematical Course—History.

William B. Wynn of North Carolina: National Law—Rhetoric, Logic and Ethics—History.

PUBLIC EXERCISES OF THE UNIVERSITY OF VIRGINIA, JULY 4, 1838.

At the close of the session, on Wednesday, the 4th July, 1838, the following public exercises took place.

The exercises were opened with prayer by the Rev. A. P. B. Wilmer, Chaplain of the University.

The names of the students who had distinguished themselves, at the public examinations held during the present session, were then announced (in alphabetical order) by the Chairman of the Faculty.

Diplomas were then delivered by the Chairman, to the following students, who had been admitted by the faculty, to graduate in the several schools mentioned:

Latin Language and Literature.

John W. Clay, Alabama.
Wm. H. Glascock, do.
Thos. J. Hungerford, Westmoreland.
P. Thornton Lomax, Fredericksburg.
Fielding L. Marshall, Fauquier.
Thomas L. Reynolds, South Carolina.
Wm. W. Roper, Richmond.
C. R. G. Slaughter, Charlottesville.
Henry Spencer, Charlotte.
Chapman J. Stuart, Richmond.
L. M. T. Wickham, do.

SCHOOL OF ANCIENT LANGUAGES.

George H. Gnerard, South Carolina.
Donald M. Harrison, Amelia.
William H. Jones, Mecklenburg.
Wm. M. Swoope, Augusta.
Lewis Turner, Louisa.
Charles D. Wharton, Goochland.
Isaac R. Watkins, Charlotte.

SCHOOL OF MODERN LANGUAGES.

French—

Richard W. Bushnell, Rockingham.
John Critcher, jr., Westmoreland.
John W. Clay, Alabama.
Thomas O. Dabney, King William.
Eugene Davis, University of Virginia.
Donald M. Harrison, Amelia.

James A. Jones, Mecklenburg.
William H. Jones, do.
Hunter H. Marshall, Charlotte.
Lewis Turner, Louisa.
Thomas Towles, Louisiana.
Thomas H. Watts, Alabama.

Spanish Language and Literature—
Robert L. Brown, Nelson.
Richard W. Bushnell, Rockingham.
Thomas O. Dabney, King William.
Eugene Davis, University of Virginia.
Donald M. Harrison, Amelia.
Wm. H. Jones, Mecklenburg.
James M. Morson, Fredericksburg.
Thomas H. Watts, Alabama.

Italian Language—
George W. Blæattermann, University of Va.
James Alfred Jones, Mecklenburg.
Lewis Turner, Louisa.

SCHOOL OF MATHEMATICS.
Richard W. Bushnell, Rockingham.
Solomon Carr, Nansemond.
James Alfred Jones, Mecklenburg.
James M. Morson, Fredericksburg.

SCHOOL OF NATURAL PHILOSOPHY.
Richard W. Bushnell, Rockingham.
Wm. S. Barton, Fredericksburg.
Solomon Carr, Nansemond.
Eugene Davis, University of Virginia.
Donald M. Harrison, Amelia.
William J. Harris, Powhatan.
Wm. W. Roper, Richmond.
Wm. B. Stanard, do.
Dabney Carr Wirt, do.
Charles D. Wharton, Goochland.

SCHOOL OF CIVIL ENGINEERING.
Wm. S. Goodwin, Southampton.
Matthew M. Harrison, Brunswick.
Calvin D. Jones, Albemarle.
George W. Randolph, do.
Wm. H. Woodis, Norfolk.

SCHOOL OF CHEMISTRY.
John B. Baldwin, Staunton.
Wm. S. R. Brockenbrough, Hanover.
George H. Guerard, South Carolina.
James Alfred Jones, Mecklenburg.
Benjamin B. Minor, Spottsylvania.
Wm. H. Phillips, Charlottesville.
Wm. R. Skipwith, Richmond.
Wm. B. Stanard, Richmond.
Thomas H. Watts, Alabama.

SCHOOL OF MEDICINE.
With the title of "Doctor of Medicine."—
Wm. F. Robertson, Alabama.
George W. Rothwell, Albemarle.
Wm. R. Skipwith, Richmond.
Wm. D. Willis, Albemarle.
Wm. P. Whiting, Cumberland.

SCHOOL OF MORAL PHILOSOPHY.
John B. Baldwin, Staunton.
James M. Browning, Alabama.
John Burruss, Louisa.
John Critcher, jr., Westmoreland.
Thomas O. Dabney, King William.
John M. Garnett, King and Queen.
Robert S. Goode, Amelia.
Thos. J. Hungerford, Westmoreland.
Wm. H. Macon, Hanover.
Benj. B. Minor, Spottsylvania.
Alfred H. Powell, Winchester.
Elverton A. Shands, Prince George.
Joseph D. Shields, Mississippi.
Wm. B. Stanard, Richmond.
Thomas H. Watts, Alabama.
Dabney C. Wirt, Richmond.

SCHOOL OF LAW.
Richard L. T. Beale, Westmoreland.
Mordecai Cooke, Norfolk.
James T. Dillard, Bedford.
Terrisha W. Dillard, do.
Wm. N. Gregory, King William.
Wm. T. Joynes, Accomac.
Peter K. Skinker, Fauquier.

PROFICIENTS IN MEDICAL JURISPRUDENCE.
Alfred H. Powell, Winchester.
John D. Wright, South Carolina.
Wm. R. Roberts, Albemarle.
Charles Carter, Hanover.
Prince M. Watson, Albemarle.

PROFICIENTS IN MATERIA MEDICA.
William S. R. Brockenbrough, Hanover.
James Norris, Charlottesville.
Wm. H. Phillips, do.

PROFICIENTS IN PHYSIOLOGY.
Wm. S. R. Brockenbrough, Hanover.
Charles Carter, do.

PROFICIENTS IN POLITICAL ECONOMY.
John B. Baldwin, Staunton.
John Critcher, jr., Westmoreland.
Benjamin B. Minor, Spottsylvania.

The following students, having graduated in the schools of Ancient Languages, Modern Languages, Mathematics, Natural Philosophy, Chemistry and Moral Philosophy, the degree of *Master of Arts,* was conferred upon them by the Faculty.
Thomas O. Dabney, King William.
Wm. B. Stanard, Richmond.

—

The session of this Institution was brought to a close on Wednesday last, by an exhibition in the rotunda, when the names of students who were distinguished at the intermediate and final examinations were announced by the Chairman of the Faculty, and diplomas awarded to those who had obtained degrees in the different schools of the University. The degree of Master of Arts was conferred upon Mr. T. O. Dabney of King William, and Mr. Wm. B. Stanard of Richmond. There were no orations delivered or Essays read —the exercises were consequently less interesting, and fewer citizens and strangers were in attendance, than is usual on such occasions. The greater portion of the students had also left college before the exhibition took place.

The Visitors formed a Board on Tuesday, and were in attendance on Wednesday. We have not heard of any changes of importance effected by them in the regulations or by-laws of the institution, except the establishment of an infirmary, in connexion with the medical department.—*Charlottesville Advocate.*

From the N. E. Farmer.

ASHES.

[We have the pleasure to present to the agricultural public the subjoined highly valuable communication; and acknowledge ourselves much indebted to the kindness of this intelligent and skilful cultivator for having at our request presented it. Our attention in passing on the road from Pawtucket to Providence had been always particularly attracted to the improvements going on on this farm, and the order and neatness which marked the premises. The last spring, on a visit to some relatives, we had the pleasure of examining the excellent management pursued at the establishment. The cultivator, it will be seen from the style of address, is a Friend. This most exemplary Christian sect are always remarkable for their neatness and order, qualities which are so valuable, and produce so much comfort in life. "Thou shalt be neat and clean, and systematic and orderly in thy person and in all thy dealings," is a commandment, which, if they have not actually added it to the decalogue, seems to have with them almost as high an authority. A slovenly Quaker is a "rare bird;" an anomaly seldom occurring. We cannot too much commend them for this. "Order is Heaven's first law." Neatness, as a friend was accustomed to remark, is next to godliness; it is essential to good manners, and almost equally so to good morals; its opposite is certainly a violation of what are called the minor morals of society. H. C.

North Providence, 6*mo.* 4, 1838.

RESPECTED FRIEND, HENRY COLMAN:--

I have never known more profitable results from the application of any manure to light and steril soils, whether loamy, sandy, or gravelly, than from leeched or unleeched ashes. They have long been used in Rhode Island with great success, especially in the growing of barley and clover, to which they seem peculiarly adapted.—As evidence of the estimation in which they are held by the farmers of the Island, ten cents per bushel have been paid for them in Newport for the last twenty years and upwards, and though considerable quantities have been furnished from different places on the sea-board, the demand for them has always exceeded the supply. They are generally used at the time of seeding, spread on an even surface and harrowed in lightly with the grain and grass seed. The quantity varying from 50 to 100 bushels per acre.

In 1833, a lot of land falling under my management which had then recently been purchased at $30 per acre, seven acres of it and perhaps the least valuable part, which in my opinion never possessed fertility, though it is usually called worn out land, being a sandy plain, gravelly subsoil, were ploughed and rolled in order to secure for the benefit of the crop what little vegetable matter had been turned under; about 1600 bushels leeched ashes were then spread on the lot, and it was sowed with 10 quarts millet and 16 lbs. southern or small clover seed to the acre. The season proved dry and the seed took badly, the crop of millet was 10 tons by estimation, and was sold for $180. 19 tons clover were supposed to have been obtained the two succeeding years at four cuttings; this too was sold for $316. The clover having nearly all perished in the winter of 1835-6 it was pastured the season following, and last year 1136 bushels ashes having been applied to it, it was again sowed with millet, and stocked as before with southern clover, 20 lbs. to the acre.—The product was 13 tons millet, for which I credited the owner $221, retaining it for my own use. Like results have been obtained from similar treatment of the same description of soil in various instances, this not having been selected because the most striking, but because the amount for which the crops sold fixes their value, without knowing exactly the quantity produced, which in each case has been supposed. The labor bestowed on the lot was more or less blended with other business of the farm; it is therefore difficult at this period of time to ascertain the amount charged. I believe however it did not exceed the charge in the subjoined account.

Cost of land,	$210 00
" Ashes for both dressings,	215 54
Seed for do.	41 25
Ploughing 10 1-2 days,	21 00
Rolling 3 1-2 do.	7 00
Harrowing 3 1-2 do.	7 00
Carting outside furrows,	7 50
Sowing 3 days,	3 00
Carting and spreading ashes,	54 00
Cutting, curing, and housing 41 tons millet and clover,	123 00
5 years' taxes,	2 10
Interest accruing on transaction,	46 00
	$737,39
Cr.	
By Produce sold, amounting to	$717 00
Value of pasturage,	15 00
Value of lot in its present condition,	385 00
	$1117 00
	737 39
	$379 61

There is reason to suppose from present appearances that the lot in question will cut two tons clover this season per acre; it will therefore be seen that my valuation is not a high one. A repetition of the treatment it has received, would no doubt improve still more the texture of the soil, but I am inclined to think there might be a falling off instead of an advancement in the amount of its productions, by subsequent ashings. Should this be the case it would indicate a suitable condition for more permanent improvement by manuring.

There is but one instance in which I can make out the exact quantity of milk sold in a year. It amounts to 11,131 1-2 gallons, this is exclusive of a supply for the family, and was produced by I suppose an average of 20 cows. There have been seasons when I think a larger quantity has been produced in proportion to the number of cows kept, but the manner in which my books have been kept, hardly ever specifying more than the amount received for the article sold, does not enable me to determine with accuracy the quantity sold in any other year. In the instance given the milk was disposed of to one person at a certain rate, which with the amount of sales being known determines the quantity. How much was used by the family is not known, probably not more than 300 gallons.

In regard to the bog there is yet but little to be said, a greater part of it being yet on the tide of experiment, whether successful or not, time will determine. The burnt part has hitherto been most productive. In 1835, 1-2 acre was pared, the turf burnt, and the ashes spread over the surface. The year following it was planted wih potatoes, the crop paying for the land at $30 per acre and all expense accruing from its improvement. Last year nothing was taken from it, it was seeded the latter part of summer, and now promises a large crop of hay.

Respectfully, thy friend,
ADAM ANTHONY.

Communicated to the Farmers' Register.

ON THE USE OF MARINE VEGETABLE MANURE.

To Joseph Ball, esq., Ditchley, Northumberland County.

Linden, Westmoreland County, July 6, 1838.

Dear Sir,

I duly received your favor of the last month, requesting me to furnish you with such information in regard to the improvement of land, by the application of "marine vegetation," as my experience in the use of it, will enable me to afford. This call for information, on a subject which I deem of vital importance to the agricultural improvement of our beautiful tide-water country, affords me peculiar gratification; and it gives me very great pleasure to have it in my power to answer it in a satisfactory manner.

My opinion in regard to the value of *kelp* or *sea-weed*, as manure, was given somewhat at large, in an essay on "*marine manures*," published in the Farmers' Register four or five years ago.* I beg leave to refer you to that essay as containing the result of my experience, up to that time. I have since applied it, with *creek-grass*, and other marine manures, upon a very extensive scale; and I may say, with the most gratifying success. In the course of about six years, I have restored to fertility the greater part of a large farm on the Potomac, that had been reduced to the lowest state of sterility, by a long course of exhausting cultivation. Upon this farm, in the course of the last year, at an expense in labor, not exceeding $300, I carried out about eight thousand loads of manure with single ox carts; and have now growing upon it, the finest corn that I have ever seen upon land of any thing like the same original quality.

The "grass" which you say has become abundant along your shores, has, of late, taken almost entire possession of the small creeks indenting our farms on the Potomac, and furnishes an inexhaustible supply of the richest manure. It is more powerful, in its effects, than the *sea-weed*, which is driven upon the river shores; and though the assertion may seem extravagant, is to be preferred to the best stable manure.

Parts of my fields are manured with each, and the most careless observer may distinguish the superiority of the corn where the "grass" has been applied. It seems to possess a peculiar quickness and power, forcing the young plants forward so rapidly, that they escape the depredations of insects, and seem to be little, if at all, affected by the coldness of the seasons, which for several years past, has retarded so much the growth of the corn. In common with the *sea-weed*, it possesses the power of attracting moisture from the atmosphere—keeping the corn green and vigorous in the driest seasons, and justifying much thicker planting, without endangering the crop, than could be ventured on with any other manure. Last year, on a lot, which had never yielded before more than four barrels to the acre, I planted corn, after manuring with creek-grass in the water-furrow, at an average distance of five feet and a half one way, and two feet three inches the other, leaving two stalks in a place. The stalks attained the height of thirteen feet or upwards, and one acre that was carefully measured, yielded nine barrels of sound corn. I have this year planted a considerable part of my crop equally thick, having more than double as many of stalks on the land, as most of my neighbors. Such thick planting as this, however, could not be recommended in our climate, even after the application of this most certain manure, except upon land that had already been improved to a considerable extent.

It is difficult for me to give you a correct estimate of the expense of manuring with the materials to which I have adverted. Having on my land an inexhaustible supply of manures accessible in some form at all times, I have been able to pursue the business of manuring as a regular system, and to devote a considerable force exclusively to that object. A considerable part, moreover, of the labor of collecting and scattering the manure and driving the carts, has been performed by children and small boys who would have rendered little or no service in any other employment. The expense, therefore, of my improvements may not be a fair criterion of the cost of manuring, under different circumstances. For this reason, I have applied to my neighbor, Mr. John T. Rice, who is a successful practical farmer, for an estimate of the expense of his improvements made with the creek-grass alone. He has kindly furnished me with a statement which you will find in his letter accompanying mine. From this you will perceive that an acre may be manured with creek-grass, at an expense of four dollars, by which the crop of corn will be more than doubled, and the land to a considerable extent permanently improved.

But many of our indolent and penurious farmers would be alarmed at the idea of incurring even this small expense. What! give four dollars for manuring an acre of land that cost only six!! Permit me here to make a slight digression. Have you ever read Black's Essay on the intrinsic value of land? It was published in an early volume of the American Farmer, and is a most ingenious and able argument to prove that every acre of land in the state of Delaware, is intrinsically worth five hundred dollars. His conclusion is somewhat extravagant, but there is much force in his reasoning. I have reflected a great deal on this subject, and I have come to the

*See Farmers' Register, Vol. I, p. 513.—ED.

conclusion that whilst it is impossible to underrate the value of poor land, supposing it to remain unimproved, it is extremely difficult to overrate the value of such as, by manuring, and a judicious course of management, has been brought to a high state of fertility; and that consequently, money and labor cannot be more judiciously expended, than in procuring and applying manures. What do you suppose is the intrinsic value of land, that in a rotation of three years will produce to the acre nine barrels of corn, twelve bushels of wheat, and a reasonably good crop of clover? And to this extent, it is not extravagant to believe that nearly every acre of land on tide-water may be improved. You will answer that an acre of such land is worth twenty, thirty, or perhaps fifty dollars. I will demonstrate that, supposing corn to sell for \$4 a barrel and wheat for \$1 50 per bushel, such land is intrinsically worth more than \$200 an acre. Col. Taylor, in his 'Arator,' estimates that each efficient laborer can cultivate fourteen acres well, on the three field system. That is, fourteen acres in corn, fourteen in wheat, and fourteen in the third shift, being in clover. The expense of cultivating an acre may be set down then at one-fourteenth of the annual cost of a laborer, including food and clothing, added to a reasonable charge for the team-work, wear and tear of implements, &c. Rating the cost of the laborer at \$112 a year, (a full estimate here) one-fourteenth of which sum. is \$8 00

And the team-work and wear and tear of implements, at	3 50
We have the cost of cultivating an acre,	\$11 50
Now what is the product?	
Nine bbls. of corn, at \$4,	\$45 00
Twelve bushs. wheat (deducting seed) at \$1 50	16 50
	61 50
Deduct expense of cultivation	11 50
Clear profit on the acre in three years,	\$50 00

Now what sum, at simple interest, will yield \$50 in three years? Answer, a sum exceeding \$270. Here then, according to the supposition, is a permanent capital, yielding a certain annual increase of more than 6 per cent. on \$200. Is the acre of land then not as well worth \$200, as a share of bank stock yielding six dollars per annum is worth \$100? I have said nothing about the value of the clover, hay, pasturage, &c., these, together with the interest in the \$70, over and above the \$200, may go to pay the cost of superintendence, and to compensate for errors, if any, in the estimates.

Pursuing the same course of reasoning, what is the value of an acre of land, that will yield in a rotation of three years, two barrels of corn, seven and a half bushels of oats, and no wheat or clover? And of this quality is more than half the land in eastern Virginia, in its present exhausted and unimproved condition.

Expense of cultivation, - -	\$11 50
Product 2 bls. corn \$8, $7\frac{1}{2}$ bush. oats, \$3,	11 00
Loss in cultivating the acre - - -	50

Value of the land less than nothing, it being a tax on the proprietor to cultivate it. I am aware that these estimates may not be entirely accurate; but they approximate to the truth, sufficiently to illustrate the great principle that I wish to enforce; viz.: that poverty and ruin are the necessary consequences of continuing to cultivate exhausted fields, while independence and wealth, as certainly result from a liberal expenditure of labor and capital in the improvement of the soil.

But to return from this digression. The best mode of applying the *sea-weed* and creek-grass, as stated by Mr. Rice in his letter, is to spread it in the water-furrow, when first hauled out; and leave it uncovered until the usual time of ploughing corn land. My practice has been to leave it in loads as carted out, until the winter and spring, when it is spread in the furrows as rapidly as possible before the plough. This plan has answered remarkably well; and when the quantity carried out is very great, it is almost impossible to pursue any other course. Mr. Rice had entertained the opinion that a great portion of the strength of the manure was lost, by leaving it in loads so long; and last year scattered a considerable quantity in the summer and fall, and listed upon it immediately. His crop was very much improved by it; but this year he has tried a fair experiment, which has convinced him against his own opinion, that it is better to leave it uncovered, or even in loads as I do, than to list upon it so early. He left six rows in his field, manured in all respects like the rest of the land, except that the manure remained upon the surface four or five months before it was ploughed in. A few weeks ago I visited his field with him. The corn on all the manured land was very fine; but, to my astonishment, after a careful examination, we found the corn in these six rows a third larger than the rest, and concurred in the opinion that it would yield a third more grain.

This, by the way, is a strong confirmation of the opinion that of late has gained ground, that surface manuring is the most efficacious.

The first application of the *creek-grass* as manure in this neighborhood, and as far as I am informed, elsewhere, was made by me on a small scale, four or five years ago. The effect was so striking, that I was induced to continue its use extensively. My neighbors, who were at first incredulous, have since been convinced of its extraordinary virtues, and commenced the use of it themselves, and now estimate their lands that are so situated as to command it conveniently, at double their former value. One of them, a plain, practical man, in very limited circumstances, and whose land is distant two miles from the water, has used it for two years, and so profitable has he found it, that last year, after getting the grass from the creek himself, he paid two shillings ($33\frac{1}{3}$ cents) a cart-load for hauling it to his fields, with the perfect assurance that he should make money by the operation.

So highly do I esteem it, that I am perfectly satisfied that the poorest land on our creeks, which in its natural state will not defray the expense of cultivation, (and the selling price of which is very inconsiderable) might be purchased even as high as \$30 an acre, and by a judicious application of this manure be made to return, in a very short time, a handsome profit on the investment. I cannot doubt, that it is destined to renovate, at no distant day, a large portion of the exhausted land of eastern Virginia.

To get the grass from the creeks, I use a common scow, built for the purpose. It is rather smaller than wood scows; and cost about $25. The grass ripens about the first of August, and becomes loose from the bottom, and is easily drawn up with rakes. I continue to get it through the fall, and in mild weather in winter. Two hands will get about twenty cart-loads a day.

There are several varieties of it, all of which I have used extensively, and with equal benefit. But there is one species more succulent than the rest, which is rapidly decomposed, when suffered to remain in loads. This kind should always be scattered as soon as carried out. The effect of this manure is striking on all crops; but it is more conveniently and profitably applied to corn. Like the *sea-weed*, it is much more beneficial on light, than on stiff land.

I have now, my dear sir, answered in substance, all your interrogatories; and I need hardly assure you, that it will afford me peculiar satisfaction, to learn that, by the information imparted, I have, in the least degree, benefited either you or the public. But my pleasure would be unbounded, if at a future day, I should learn, as I confidently trust I shall, that, by the use of the means, to which I have called your attention, and others equally within our reach, extensive tracts of land now waste and unproductive, have been restored to fertility; the tide of emigration checked, a restless and dissatisfied population rendered contented and happy; and prosperity, abundance, and wealth extensively diffused over our beautiful, but hitherto neglected country.

Whilst I regret to learn that you are prevented by age and infirmity from the active superintendence of your farm, permit me to congratulate you that your zeal in so noble a cause is not extinguished; and to remind you that "there are pleasures in rural affairs, (for which we have the high authority of Tully,) perfectly consistent with every degree of advanced years, as they approach the nearest of all others to the purely philosophical kind. They are derived from observing the nature and properties of this, our earth, which yields a ready obedience to the cultivator's industry, and returns with interest, whatever he deposited in her charge; if not always indeed with equal increase, yet, always with some." Nor can I refrain from expressing my satisfaction that you are instructing your son, for whose benefit the foregoing information has been sought, in the art and science of husbandry. Such examples are calculated to produce the happiest effects. Virginia can never be what she ought to be until the minds of our educated young men take a proper direction. The rage for speculation, politics, and the miscalled liberal professions must abate, and agriculture assume the position to which it is entitled among the noblest pursuits of educated and enlightened men, before the physical resources of our state can be properly developed, or the moral and intellectual faculties of our people, cultivated to their full extent. In ancient Rome, there were many signal examples of the high estimation in which agriculture was held by the most illustrious characters. Curius Dentatus, after having conquered the Samnites, the Sabines, and even Pyrrhus himself, passed the honorable remainder of his declining years in cultivating his farm. Cincinnatus was following his plough, when notice was brought to him that he was appointed dictator. And all the venerable senators of that age, as we are informed by Cicero, constantly resided at their villas, and were employed in rural affairs. The writings of Cato, Varro, Virgil, Pliny, Columella, and others, may satisfy us, that the cultivation of the earth and of elegant letters, were in ancient times deemed by no means incompatible. And the noble example of our illustrious Washington, who amidst the cares of state and the ceremonies of office, retained in an eminent degree his taste for rural pleasures, and his desire to benefit his countrymen, by the dissemination of useful knowlege on every branch of agriculture, inculcates the useful lesson that the practice of husbandry, whilst it calls into exercise the finest feelings and faculties of our nature, is not beneath the dignity of the most exalted in station, or gifted in intellect. Agriculture can no longer be considered a mere mechanical employment. The physical sciences, the wonderful creations of modern times, are so intimately connected with it, that it cannot be pursued with pleasure or its greatest profit, without some knowledge of their principles, derived either from the study of books, or from the practice of others. It is, now, therefore, peculiarly proper, that the rising generation should be educated with the view to the pursuit of agriculture as a profession. And if the happy period shall ever arrive, when a class of well instructed farmers shall supply the places of the speculators, demagogues, quacks, and pettifoggers that now swarm over the land, we may expect to see the natural resources of our beautiful state fully developed, and her moral, political and intellectual character elevated to the highest standard of excellence, that has ever been attained by the most distinguished nations of ancient or modern times.

But I have wandered from my subject, and shall weary you with these speculations. Permit me in conclusion, to express the hope that amidst the peaceful scenes by which you are surrounded, you may enjoy long life, and a useful and happy old age, and to subscribe myself, with sentiments of sincere respect and esteem, yours,

WILLOUGHBY NEWTON.

To Willoughby Newton, esq.
Westmoreland Co. Va.

Laurel Spring, June 20, 1838.

Dear Sir—According to your request, I furnish you with what I believe to be a correct estimate of the cost per acre to manure my land with creek-grass. On land convenient to the creek, with five men and a cart, I got up, hauled, and scattered fifteen large cart-loads per day; which manured a half acre. The cost of the laborers, including food, clothing, &c. at the average price of farm labor, was about as follows:

Five hands at 32 cents per day, -	$1 60
One cart and two yoke oxen,	40
	2 00
Which is per acre,	$4 00

This may, at the first view, appear to be a costly way of manuring, in proportion to the price of poor land, but if we consider the great increase in product, it is evident that it is the most profitable way that the labor can be applied at that season of the year, (from the middle of July to the last of

September.) I am confident, from the result of an experiment that I made last year, and the appearance of the present crop, that a manuring with the creek-grass will double the crop of corn the first year.

From experiments that I have made, I find that the best way to apply the creek-grass is to scatter it in the furrow between the old corn-beds, without ploughing it in until the following spring, at the usual time of listing for corn.

The scow that I make use of to get the grass out of the creek, is twenty-five feet long, from eight to nine feet wide, and fourteen inches deep, with a deck. The scow cost, including every thing about thirty dollars. I make use of rakes and pitch-forks to get up and handle the grass with.

I remain yours, respectfully,

JOHN T. RICE.

COVERING COTTON SEED WITH THE COULTER. BENEFIT OF PLOUGHING CLAY-SOILS AFTER RAIN.

Rockbridge, Va. June 23, 1838.

About the 20th of last month, (May,) I planted our *cotton patch*. A part of the seed, (all of which had been soaked in warm water for a few hours, and then rolled in plaster,) was covered with a hoe, say two or three inches deep; the other and larger part, by running a coulter a single time along the drill and through the seed, plentifully scattered in the row. This operation covered most of the seed, and probably at various depths, from one-fourth of an inch to three or four inches. In a few warm days, the cotton *coultered in* was regularly and beautifully up; but not a grain of that covered with the hoe; nor did the latter come up for a week after, nor until the surface of the ground, which in the mean time had become cohesive from a heavy rain, was broken with a rake. It then began to come up very leisurely, and as yellow as saffron; and is now at least ten days in growth behind that covered with the coulter.

Again, having ploughed over a field of corn, from the 1st to the 10th instant, I began, a day or two afterwards, to reverse that operation, by running a two-horse harrow over each row of corn. This was continued for a day. We then had a heavy shower of rain, which stopped the harrow for a day or two, when it was again started, and the field finished. I had, lately, several times heard my overseer say that there was a great difference in the corn that had been harrowed before and after the rain. I supposed it imaginary; but being in that part of the field yesterday, where the hands were ploughing, I was surprised at the difference in the corn, *to a row*. That which had been harrowed before the heavy rain above-mentioned, was hardly knee-high, the blades generally yellow and somewhat striped, while the rows adjoining, and throughout that part of the field harrowed after the rain, on land of the same quality as that harrowed before it, was waist-high, and of a rich green color. Not remembering at the time what the overseer had said about the difference in the corn harrowed before and after the rain, I accused him of negligence in the application of plaster, when planting the corn. He affirmed and insisted that all had been plastered alike. The boy who had been charged with dropping plaster on the corn just before it was covered, and the hands that covered it, all supported the affirmation of the overseer. Well, then, if by the testimony of two or three witnesses, every word is established, there is a benefit in working our clay-lands after heavy rains, of which I had often heard, and sometimes seen instances, but never one so striking as in the case just mentioned.

R. GRIGSBY.

[We know how to appreciate the good effects of the mode of covering cotton seed above described, by the experience of five years, during which (much to the detriment of our farming and farm-improvement) we were engaged largely in cotton-culture. The plan of covering then pursued, though in principle the same with Mr. Grigsby's, was far more expeditious and economical. After the seed (without any preparation of wetting or otherwise) had been strewed along the shallow furrows made to receive them, large two-horse harrows, (or drags,) or two smaller harrows coupled together, with straight and pointed teeth, were passed over the whole surface, just as if to cover wheat. The direction of the course was generally the same as that of the cotton-rows; but this was not important, as in crossing, at the ends of the lands, there were very few seeds drawn out of the rows. The seeds were well separated, and mixed with soil, by this operation, and placed at all depths, from the surface to two or three inches below. The coming up well of either the upper or lower seeds was almost certain. Though we have abandoned cotton-culture, the same mode of covering seed we still practise on all old corn-land; and continue to approve of it as a great saving of labor, and at the same time, as helping much the tilth and good condition of the field, by the thorough and deep harrowing.—ED. FAR. REG.]

From the Genesee Farmer.

AGRICULTURAL CHARLATANISM.

We perceive in our agricultural papers notices of the method of making manure discovered by M. Jauffret, and some of our contemporaries seem to consider it as almost miraculous. We may as well say here, as we think we have not noticed the matter before, that M. Jauffret professed to be able to change by means of a lie, used by sprinkling straw, leaves, plants, even woody stalks of a finger's thickness into first rate manure in an incredibly short space of time. The preparation was kept a secret, and the announcement caused a great sensation in France and England. A committee of the French Academy of Agriculture gave their testimony in its favor, and demands for the right of using, or the sale of the liquid, flowed in upon M. Jauffret from all quarters, while the cash that accompanied the orders, rapidly accumulated in his pockets. A proposition last year to invite M. Jauffret to England, from some circumstance failed; but some English gentlemen visited Paris at the expense, we believe, of the London Farmer's Magazine, for the purpose of determining the value of the invention. Their report was decidedly adverse to the process, and the examination showed that the greatest frauds had been practised on the community. M. Jauffret is dead, and a chemical examination proved it to be only an alkaline solution, good in its effects on the soil, of course, but utterly incapable of performing the effects claimed by the inventor. There is no magic, we had almost said no mystery, in the preparation of manure. It is the result of animal or vegetable decomposition; and what has once been the constituent part of plants, is more readily adapted to their use, than matter which was never under the process of vegetable or animal organization. In the application of science to agriculture we are entitled to expect great improvements, but not miracles, and any process that claims a result approaching to this may well be looked upon with suspicion.

Since writing the foregoing, the last number of the London Magazine has reached us, and from it we make the following extract.

"*The New Manure of Jauffret.*---A friend of ours has obligingly written to a large landed proprietor in France, who is a member of the chamber of deputies, making inquiries respecting this man, and his *invaluable* manure, when it turns out that he is one of that class of charlatans, of which there are so many at this time practising deception on the agricultural community. It appears that the old peasant has lived in clover these last two years, and duped dozens of Mayors, Prefects, and other functionaries, and taken the cash of hundreds of subscribers. "Our friend's informant, who was himself one of the dupes, states that the new manure costs double the price of ordinary manure. The author of this *valuable* discovery it seems is dead. Had there been a National Agricultural Institution in existence in this country, having individuals connected with it ready and competent to examine into such pretended discoveries, this *swindler's* tricks, as well as those of many others, would long since have been exposed."

For the Farmers' Register.

AGRICULTURAL NOTES OF A TOUR IN THE WEST.

Nelson County, Va., July 12th, 1838.

Dear Sir—I left Baltimore, on the 31st of March, for the west, by the railroad to Fredericktown in Maryland; and passing over a poor stony and hilly country for the first forty miles, reached that place a little after noon. The country, as you approach Frederick, opens into a beautiful valley, well cultivated, and at this time presented numerous fields of wheat, very luxuriant in appearance. Contrasted with the wretched region in the neighborhood of Baltimore, it appears to great advantage. Valley succeeds valley, with little difference, apparently, in soil or culture, until the traveller approaches the Alleghany range of mountains. The passage across them, however fertile in scenes interesting to the "eye of taste," affords little to engage the attention of an agriculturist, except the fine national road, over which the eastern and western commerce and travel are here conducted. To us in the south, who have been struggling since the first settlement of the country with the worst modes of conveyance for our agricultural products, it is edifying to see what an immense amount of labor may be saved in the transportation of crops to market by the construction of good routes; and, consequently, that a great enhancement in their value, results from the diminution in the charge of transportation.

Fifty-six hours of constant travelling carried us from Baltimore to Wheeling; yet, so good was the road, although across lofty mountains, and so easy to sleep in the coach, that the journey was attended with very little fatigue.

The vegetation on the Ohio seemed at the first glance to be of a much richer and deeper green, than any in the east, although the uncommon coldness of the spring had retarded both so much that very little more than the first traces were visible on either side of the mountains. A steamboat ready to depart, afforded an immediate opportunity of descending the Ohio, and, in about thirty-six hours after leaving Wheeling, I was landed at Portsmouth, at the termination of the Ohio and Erie Canal. The navigation of the canal was just resumed, after the winter's suspension, and taking a passage in an excessively crowded canal boat, I arrived at Chilicothe on the following day. During this rapid journey, I had an opportunity of seeing the wheat-crop was exceedingly promising every where, but more particularly so along the course of the Ohio and up the Scioto. Reposing here some time, I received information, in several respects, of the trade and agricultural productions of this very rich valley, which may possibly not be uninteresting to some of the readers of your useful journal, although it is far less extensive than I wished.

The Scioto river is bounded by exceedingly rich and extensive flats, the dark alluvial soil of which varies from one to eighteen feet in depth, and possesses a proportionate fertility. From sixty to eighty bushels of corn to the acre are produced from lands long and successively cultivated in that crop; and there are well authenticated cases of from 120 to 160 being obtained from fresh lands, by good and careful culture. There are instances where the same field has been cultivated for forty years in succession in corn, with very little diminution, to the eye, in its product, at least for the last thirty years. These grounds yielding so abundantly in corn, are too rich to be safe for wheat, although good crops are sometimes obtained. But the neighboring highlands produce small grain of all kinds most bountifully, and all the most valuable grasses in great abundance. It may be imagined that a country endowed with such capacities for rearing live stock would have a portion, at least, of its capital applied in that manner. And that was the case to a great extent before the construction of the Ohio and Erie Canal opened the markets of New York and New Orleans to the productions of the soil. Even now that trade affords employment to the resources of many of the most wealthy landholders. Large numbers of cattle purchased westward of the Scioto valley, in addition to those bred in it are either fattened there for market, or being kept for some time, are sold to persons living in the eastern states, to be by them prepared for the consumption of eastern purchasers. Hogs too, to a very large amount, are fattened, and either driven eastward, or are slaughtered and salted for exportation. Mr. George Renick, who resides near Chilicothe, is a large landholder, and has long been an extensive and successful dealer in cattle, did me the favor to answer some queries in relation to the cattle trade, which I will subjoin in the language in which they were propounded and answered, thinking it better to give his own words, than any version of mine. My questions were the following:

1. What is the probable number of cattle annually sold from the Scioto valley ?

2. What proportion are bred in it, and how many purchased elsewhere?

3. In what parts of the country are those procured that are purchased, and how far from the Scioto are the remotest points?

4th. How long are they kept after purchase, how treated when sold, and at what advance upon the purchase money?

5th. Are they driven directly from the Scioto valley to the places of consumption, or do they stop for any length of time at intermediate points, for further preparation for market?

6th. What are the chief markets for the cattle when finally disposed of ?

7th. What will be the probable advantages of the introduction of the English cattle into this region, and which of the English breeds are most esteemed?

Any information deemed pertinent, and not comprised within the scope of the foregoing queries, will be thankfully received in addition to their answers.

The following answers were given :

To question 1st. About thirty-five thousand head, one-third of which are corn-fed.

2d. One-third bred in the valley.

3d. They are procured from Missouri, Arkansas, Indiana, Illinois and Kentucky. The most distant point, one thousand miles.

4th. They are kept from six to eighteen months, some fattened and wintered, others corn-fed, then an allowance of half a bushel of corn per day, for five months. The fat cattle are sold in the spring, and the stock cattle in the fall. The advance on the purchase-money, say five dollars per head, for stock, and fifteen for fat cattle.

5th. The stock cattle are driven east of the mountains, and are kept one season. The fat cattle are driven immediately to the place of consumption.

6th. The markets are Philadelphia, New York, Baltimore, and Boston. Some are sold at Pittsburg and Detroit.

7th. The advantages of the English breeds are, being easier kept, of larger size, fattening at an earlier age, their beef being of a superior quality, and being better milkers. The Devonshire short-horns, or Durham, are supposed the best breeds.

The quantity of hogs supplied by the Scioto valley annually for distant markets is also very considerable. Messrs. John and G. Wood, large and successful dealers in pork at Chilicothe, were good enough to furnish me with a statement of the quantity supplied by the valley, and country contiguous to it, as will appear from their estimate subjoined.

Pike County,	3,000	barrels of	pork.
Ross	16,000	"	"
Pickaway,	10,000	"	"
Franklin,	12,000	"	"
Fairfield and Licking,	15,000	"	"

Total, 56,000 bbls. of pork at $15 =	$840,000
Bacon and lard equal in value to the above,	840,000
40,000 hogs are driven to the eastern and western markets at $5 per head,	200,000
	$1,880,000
About 100,000 barrels of flour are annually furnished by these counties, which, averaged at $5 per barrel, is,	500,000
Add $700,000 for the returns from the cattle trade which I have computed to be the probable amount from Mr. Renick's statement,	700,000
	$3,080,000

It will appear that the income of six counties contiguous to the Scioto, from three articles, cattle, pork, and flour, is three millions and eighty thousand dollars annually.

The commerce of the country, however, includes many other things, as will be seen from the subjoined table of articles cleared at the Collector's Office at Chilicothe, from December 1st, 1835, to December 1st, 1836.

1,219,711	lbs.	Bacon,
739,141		Lard,
77,780		Coarse grease,
205,592		Iron,
154,840		Merchandise,
70,947		Leather,
37,946		Butter,
21,664		Castings,
14,063		Wool,
8,754		Broom-corn,
6,164		Feathers,
2,277		Candles,
373,369	feet	Lumber,
121,385	bsh.	Corn,
26,898	"	Wheat,
10,235	"	Oats,
4,053	"	Flax seed,
110	"	Potatoes,
25,221	bbls.	Flour,
15,945	"	Pork,
58,000	"	Pork in bulk,
1,675	"	Barrels Whiskey,
240	"	Bbls. and 600 bushels apples,
178	"	Barrels of beans,
43	"	Pair Racoon buhr millstones,
31,000	"	Bricks,

The Messrs. Woods state they think one half of the pork trade goes to the northern, the other half to the southern markets.

	Dolls.	*Cts.*
Amount of tolls received at this office from December 1st, 1835, to December 1st, 1836,	19,027	31
Tolls received from December 1st, 1834, to December 1st, 1835,	11,857	93

Increase over 1836,	12,097 69

WM. H. SKERRETT, *Collector.*

It is an interesting fact in the statement from the collector's office, that the tolls received should have undergone an annual increase, and that during the year 1837, notwithstanding the manifold inconveniences sustained from the disorder of the currency, and consequent embarrassments of the commerce, the increase over the preceding year should have been at that place alone $12,097 69.

In fact roads and canals, like just and equitable government, produce in their operation so many unforeseen advantages, it is impossible properly to appreciate them, until their benefits are experienced. And there is scarcely any country, where persons and property enjoy tolerable security, in which it would be unwise to construct them at any expense within the power of the inhabitants or government to pay. The Ohio and Erie Canal, which passes through the valley of the Scioto, has more than doubled the value of all the arable lands within ten miles of it throughout its whole route, and its beneficial influence is felt over a much wider surface. The income derived from land in many instances has been increased from four to five hundred per cent.

In addition to a highly fertile soil and salubrious climate, recent geological discoveries have shown that Ohio possesses mineral treasures to an incalculable amount, and chiefly in that part of her territory, that seemed least gifted with the means of yielding other productions. Professor W. W. Mather, (principal geologist,) in his report to Joseph Vance, esq. governor of Ohio, says—"From the reconnoissance of the past season, it is estimated that about twelve thousand square miles of the state are undoubtedly underlain by coal, and five thousand by workable beds of this valuable mineral. In many places several successive beds of the coal are superposed one over the other, with sand-stone, iron-ore, shale, or limestone intervening. The coal-beds are favorably situated for working, as they are found in the hills and ravines, where they can be drained with little expense, and without deep shafts and expensive machinery, like those of Europe, or some parts of our own country. Probably a mean thickness of six feet of coal, capable of exploration, over five thousand square miles, is a moderate estimate of our resources in this combustible." (p. 1.)

Dr. S. P. Hildreth, in his report to Professor Mather, (p. 2,) says: "That portion of the coal measures of the valley which lies within this state, occupies a space of about 180 miles in length, by 80 in breadth, extending in a south-westerly and north-westerly direction along the borders of the Ohio, from Trumbull county to the mouth of the Scioto. These immense fields will furnish fuel for a larger population than the soil of Ohio can support for ages; and when the surface beds are exhausted much thicker ones will be found, by sinking shafts to the depth of a few hundred feet, as all coal-beds are thinner in their out-crop, or near their margins, than in the centre of the basin. Of this fact we have proof, not only from foreign fields, but from the disclosures made in boring salt-wells in our own state."

"At a very low calculation (says another member of the geological corps, C. Briggs, jr.) of the amount of good iron-ore, in the region which has this season been explored, it is equal to a solid unbroken stratum, sixty miles in length, six miles in width, and three feet in thickness. A square mile of this layer being equivalent in round numbers to 3,000,000 cubic yards—when smelted will yield as many tons of pig iron. This number multiplied by the number of square miles contained in the stratum, will give 1,080,000,000 tons, which from these counties alone, (Lawrence and Scioto) will yield annually for 2,700 years, 400,000 tons of iron; more than equal to the greatest amount made in England, previous to the year 1829."*

"In reflecting upon the prospective importance of the iron business to Ohio, a question naturally suggests itself, as to the necessary supply of fuel. Perhaps no fears need be entertained on this head, as the introduction of the hot blast, and the probability that some beds of bituminous coal will be soon brought into use for the smelting of iron-ores, render it nearly certain, that this branch of industry will never receive a check from an insufficient supply of fuel."†

Another valuable mineral (the buhr stone) is most abundant in the same region. It came into use for millstones about the year 1807. "The early manufactured millstones were made of a single piece, but these often proving to be of unequal density, and not making good flour, were abandoned, and stones constructed of separate blocks, cemented with plaster, and coupled together with iron bands. Where these blocks are selected with care by an experienced workman, the flour is said to be equal in quality to that made by the French stones. From the year 1814 to 1820, the price of a pair of 4½ feet stones was $350, and a pair of 7 feet sold for $500, while the foreign article sold for a still higher sum. The 4 feet stones now sell for $150. The manufacture of mill stones is not confined to the waters of Racoon; but is also carried to a considerable extent in Hopewell township, Muskingum county. The quantity is apparently inexhaustible.—(*Geological Survey*, p. 33.)

Limestone exists in great abundance, of various qualities. "The limestones of this series are interesting, (says Mr. Briggs,) not only as affording a flux for the iron-ores of this region, and lime for the various uses to which it is usually applied, but are also of great value for agricultural purposes. * * * Three layers of limestone have been observed. The second stratum of limestone is from 18 inches to 8 feet thick where it has been observed. It is uniformly of a dark color, nearly black, and contains the remains of radiated and molluscous animals of marine origin. This limestone breaks out into oblong blocks, of suitable size for building purposes. The organic remains will add greatly to its beauty when polished." "Since writing the above," (Mr. Briggs adds in a note,) "a piece of this dark fossiliferous limestone has been polished. It is nearly or quite equal in beauty to the best Egyptian marble. If it can

* Geological Survey of the State of Ohio, p. 93–6.
† Do. pp. 93 and 94.

be obtained in sufficient quantities, and in blocks sufficiently large, as I think it may, it will be of immense value for ornamental architecture."—(*Geological Survey*, p. 82.)

When we take into consideration the wonderful fertility of the soil of Ohio, its vast and various mineral wealth, its central position in regard to the Union, its easy communication with the great mercantile cities, by prompt and easy steamboat navigation, or by canal and railroad carriage, as New York, Philadelphia and New Orleans—that the routes of the most important character, yet in contemplation, as those of Virginia, and South Carolina, with her associates, will, when finished, terminate there—it seems an obvious conclusion, more particularly when the sagacious, enterprising and persevering character of the people of Ohio is considered, that that country is destined speedily to attain the condition of one of the most adorned of the United States.

Leaving Chilicothe about the 25th of April, I returned by the canal to Portsmouth, and took a steamboat there for Cincinnati. Although long familiar with the valley of the Ohio, I was never so forcibly impressed with its beauty before. The majesty of the river, the fertility of the lands that bind it, the rich verdure of the forest just expanding into leaf and crowning the gently sloping highlands, that in some cases come near the water's edge, and afford the most beautiful situations for dwellings on their summits. The neat farms, and country houses, and thriving villages, presented an assemblage I have never seen surpassed, perhaps not equalled. This scene seems to have warmed the imagination of the coolest and most judicious of those foreigners who have recently visited our country. "The river (says M. de Tocqueville) which the Indians named by way of distinction the Ohio, or the 'Fair River,' bathes with its waters one of the most magnificent valleys, that man has ever made his residence."* The regrets of that gentleman for the loss of this fine country to France are feelingly expressed, (p. 299,) as are those of another lively and agreeable traveller, M. Michel Chevalier, who has been recently its visitor.†

The abuse of English travellers, and the regrets of the French, both springing from sorrow felt for the losses sustained by their respective nations, of territory within our boundaries, destined to become the seat of a mighty empire, however differently expressed, enable an American to calculate the value of his country in the eyes of foreigners. Indeed, the pertinacity with which the British cling to a little slip of territory on the northern boundary of Maine, to which they have no manner of right, is irrefregable evidence of their estimate of American soil. Nothing but a breach of the union can prevent our attaining a power, both by land and sea, in comparison with which the western nations of Europe must appear perfectly insignificant. We have no reason now to fear or envy any of them, and as their intercourse with us is reciprocally beneficial, I hope it may continue to be our policy to cultivate amicable relations with them.

From Cincinnati, I ascended the Ohio to Pittsburg, and was exposed as far as Wheeling to the danger of bursting boilers, in consequence of a race between the boat on which I took passage, and one which left Cincinnati an hour or two after us. Pittsburg, with its dark and lurid coal-smoke atmosphere, offers little to check a traveller's impatience to continue his journey. I left it the evening after my arrival in a packet canal-boat for the east. The boat departed about nine o'clock at night, and I was consequently deprived of seeing the country in the vicinity of the town, and along the Alleghany river.

The next morning found us near the junction of the Alleghany with the Kiskeminetas, and along the valley of the latter the canal passes on the route to Johnstown, at the western base of the Alleghany. This valley is generally narrow and rugged, abounds in sandstone, and the forest growth is chiefly oak. Vegetation on the 27th of April was just discernible on a few trees, near the margin of the river. A few patches of wheat looked well, but the whole aspect was dreary and barren, contrasted with the rich verdure of the Ohio valley. We arrived at Johnstown in the night succeeding that we left Pittsburg—the distance about one hundred and twenty-six miles—and the next morning about sunrise were transferred to the railroad, which crosses the Alleghany mountains, and communicates with the eastern portion of the canal, at Hollidaysburg. The distance from Johnstown to Hollidaysburg is between forty-two and forty-three miles, and there are ten inclined planes, five for the ascent, and five for the descent of the mountain. The cars are raised and lowered by means of a powerful rope attached to them, and worked by a stationary engine at the summit of the plane. The passengers' cars are detached at those planes from those that carry produce, and are raised and let down first, then the produce cars undergo the same process, and are reunited, at the foot, or summit of the plane. This I understood was intended to secure the passengers from accidents that might arise from overstraining the rope. And it seemed a wise precaution, for, with all their care, one cannot help feeling that their lives depend as much on the strength and secure fastening of the rope, as if they were suspended by it a mile in the air. Accidents do sometimes happen, with every precaution, an instance of which occurred about a fortnight previous to the time I was there. Two cars, loaded with flour, became detached from the train, and rushing with fearful velocity down the plane, were crushed to atoms with their loads. The sense of insecurity, from travelling across this mountain, is so extensively felt, that I was advised by several friends in the west to avoid this route on that account; and those who know the western people, and their general reckless disregard of danger, know that their cautions, on such subjects, are rarely lightly given. But my curiosity overcame my prudence, and on arriving at Hollidaysburg, about two o'clock, I felt pleased that I had paid no dearer for its gratification. "There are in the Alleghanies, (says the pleasant traveller I have before quoted, M. Chevalier, speaking of railroads,) those which present inclin-

ed planes with frightful declivities; these were only intended for the transportation of merchandise; but it is now announced that travelling coaches *(des diligences)* are established, at the risk of breaking the necks of the travellers."*

Descending the valley of the Juniata, through the counties of Huntingdon, Juniata, Perry, &c. to the junction of the Juniata with the Susquehanna, and following the course of the latter river, we reached Harrisburg, the seat of Pennsylvania government, about midnight, and in about thirty-six hours after leaving Hollidaysburg. The valley of the Juniata is wider, and far better cultivated than that of the Kiskeminetas. The houses of the farmers are mostly of brick or stone, and good comfortable dwellings. The farms were in neat order, and the wheat fields looked very luxuriant. Farming land in this valley, I was informed, sold at about forty dollars an acre, containing an average portion of highland and low ground. The highlands seem generally to be but of moderate quality, and the mountains, which bind the valley throughout, are poor, steep, and rocky, and bear only a few scrub pines—resembling very much the mountain range between Fincastle in Virginia and the Sweet Springs. Indeed I felt quite surprised to find so large a part of Pennsylvania poor and mountainous. The traveller does not escape from the mountain region until he approaches the neighborhood of Harrisburg, and in passing from Pittsburg to Philadelphia, he sees nothing but narrow valleys and poor mountains, for three-fourths of the distance.

Since the valley of the Juniata has been canalled, the farmers sell every thing they have to spare, in the form of provisions, at good prices. Butter at twenty cents, beef at ten cents per pound, &c. The captain of the canal-boat informed me these prices were readily given, every thing being nearly equally dear, and it was difficult to procure an adequate supply even at these rates. No money but of the best kind would be taken in payment.

At Harrisburg, a railroad commences, belonging to a private company, to which travellers of the packet line are transferred, and which communicates with the state railroad, from Columbia to Philadelphia. A rapid transit of one day over this space, afforded little opportunity for agricultural observation. I noticed, however, in the neighborhood of Harrisburg, some galled and gullied fields, (a sight too familiar to the eye of a Virginian.) I did not expect this from the reported excellence of Pennsylvania farming. In the counties of Lancaster and Chester, the farms appeared small, (judging from the great number of good dwelling-houses in the vicinity of each other,) and the cultivation good. But the soil did not seem to possess the fertility usually ascribed to it. Many farmers were actively engaged in liming their fields, I presume for corn. The wheat crop looked worse than I had seen it any where, throughout my whole journey.

It must occur to a most superficial observer, that the country traversed by railroads and canals from Philadelphia to Pittsburg, is greatly inferior, in natural advantages, to that through Virginia, contemplated for the James River and Kanawha improvement. The open country of Virginia, is at least as good as that of Pennsylvania, and her mountain region is incalculably superior. That of Pennsylvania being steep and steril, with the exception of a few narrow valleys, while the mountainous portion of Virginia is very fertile, the valleys being rich and extensive, and the ridges arable to a great extent, and where not so, in most cases capable of affording good pasturage. It is plain, in a mere pecuniary point of view, Pennsylvania can only receive compensation for her great and spirited works, from the western trade. Virginia, exclusive of the western trade, for the enjoyment of which she will have many advantages, will be repaid by the improvement and traffic of her own territory, which has now scarcely any outlet to market, and is in a situation similar to that of the western part of the state of New York before the construction of the Hudson and Erie canal.

Very large quantities of produce and merchandise are transported on the Pennsylvania canal and railroad. The tolls received on that line, from the opening of navigation in the spring to June 2, of the present year, amounted to $561.635. 74. The price of transportation, too, is quite moderate; the carriage of a barrel of flour from Pittsburg to Philadelphia amounting only to one dollar and twelve and a half cents, over a distance of four hundred and seventy-three miles, it being actually less than it often costs to send one from this neighborhood to Richmond, very little more than a fourth of the distance.*

When will the people of the south learn to avail themselves of the blessings Providence has showered around them? Never, I fear, until the wealth and strength of the nation is irreparably concentrated in the north. I am by no means envious of our northern brethren. I heartily wish them success in every legitimate enterprise; but I really feel mortified, that they should so far exceed us in all the enterprises of public utility. It is said of Dean Swift, that riding out in his latter years, in the neighborhood of Dublin, he saw a new building going up, and asking what it was, was told it was a magazine. He expressed himself in the following impromptu, which I am obliged to quote from memory:

"Here's a proof of Irish sense,;
Here Irish wit is seen:
When nothing's left that's worth defence,
We build a magazine."

And when nothing is left worth struggling for, we will prosecute works of internal improvement.

My journey afforded nothing worth communicating from Philadelphia to Virginia.

Thos. Massie.

*Lettres sur l'Amérique, du Nord, Tome Jer, p. 133.

* I have seen it recently stated in the National Intelligencer, that tobacco this season has been brought up the Mississippi to Pittsburg, and transported thence by way of the Pennsylvania canal and railroad to the Baltimore market.

MOWING.

This is one of the most important operations in farming; a great deal of this work is to be done in a short time, and in a warm season, and it is of the greatest importance to lighten the labor as far as possible. We have seen some very stout hardy men toil and sweat all day, and do but a small day's work, while other men of much less strength would cut more grass, and yet not exert themselves to fatigue. From this it is evident, that some mowers exert twice the strength that others do in performing the same work, and those who use the least strength usually do their work the best, though they may not render the field so smooth, by cutting off the tops of knolls, stumps, stones, and other impediments that intrude themselves among the thick grass.

There are several reasons why there is so great a difference in expense of labor; there is a difference in sneads and scythes as to their hanging well, and there is so great a difference in scythes as to their cutting with ease and holding their edge, that some are better worth five dollars than others are worth one cent. Some men keep their scythes in prime order, and in mowing they lay their strength out to the best advantage; they use a gentle motion that will not fatigue; they are less liable to strike stones, &c. than those who make greater exertions, and when they do strike them, less injury is done.

The best scythes should be chosen, as the difference in price between a very good one and one that is good for nothing, is a mere trifle; indeed the expense of a good scythe is less than its value above a poor one for only one day's use. A scythe should hang light and easy, so that in mowing no exertions will be necessary excepting to swing the scythe and hold it steady. We have seen some scythes and sneads, or things that had these names, so rigged that the strength of one man was necessary to hold them in a proper position, while that of another was needed to swing them; of course, by having a good scythe, well hung, one-half of the labor will be saved.

With good rigging and a good scythe kept sharp, a gentle swing of the scythe will be sufficient to do as much as is performed by those who get along by main strength instead of wise management. The motion of the scythe on even ground should be horizontal, by *pointing in and pointing out*, as the saying is, cutting the grass square at each side of the swath. Some mowers who labor hard, waste half of their strength, and do bad work, strike it over the tops of the grass, cutting it off lower and lower as the scythe approaches the middle of the swath, then rising as it goes to the other side; so that the middle of the swath for only about one-third of the width is cut sufficiently low. This is called the *square lop*, and it often brings the scythe in collision with obstructions in the middle of the swath, while one fourth or more of the grass is left on each side. At a mowing match, an old gentleman was showing his sleight at taking the *square lop*, when his scythe, by some unaccommodating substance in the grass, was made into the shape of a rainbow.

Those men who labor to great disadvantage in mowing should get some that are well skilled in the business to select and hang their scythe, and give them lessons in their work. We think this would be good economy.—

With a little trouble they could improve so as to perform more labor and save ten or twelve dollars' worth of strength in one season; this item saved annually will be very important to one who wishes "to make a stout old man."—*Yankee Farmer.*

From Loudon's Gardeners' Magazine (for June.)

JAUFFRET'S NEW MANURE.

Since our remarks on this subject were published, we have received an opinion of it from one of the most scientific agriculturists in France; been made accquainted with all the particulars of the secret; conversed with M. Lozivy, the agent for granting licenses for La Manche; and seen a quantity of the manure prepared by him on Lord Spencer' sestate,at Durnsford Lodge, near Wandsworth; in short, we have satisfied ourselves as to what the invention is, and what it is worth in this country. The following is from our Paris correspondent:—

"I have not yet decided upon the question of the *engrais Jauffret*, although I have long been a subscriber. The following is, however, the opinion I have formed of it:—This compost is not equal to farm-yard manure, particularly as to duration; so that in the neighborhood of large cities, or in countries where an advanced state of cultivation furnishes the land with all the manure necessary, this practice would not be useful, or, at least, only in a slight degree. But in districts where agriculture is backward, where, for want of dung, only a half, a third, or even a fifth part of the manure is applied that the land requires, and where there are immense tracts of heath and sandy plains, that is to say, land covered with materials for the compost; in such districts, the practice of Jauffret is calculated, I think, to be of very great service. The characteristic feature and principal merit of this invention is, to convert in a few weeks, by means of a fermenting liquid, masses of these vegetable substances into real manure, or, more properly speaking, into perfect vegetable mould, which may be used immediately. It will come dear, I think, dearer than animal manure, near large cities; but probably less dear than the old composts, which required to be turned three or four times, and to lie six months, a year, or more; while in this case the object is effected in nineteen or twenty days. In France, where we have still almost entire provinces covered with heath and rushes, the Jauffret compost must be very useful. It will be useful also, I think, in the cantons, where the vine is cultivated. In England, where agriculture is much more advanced than in France, and the production of manure incomparably greater, it would certainly be of much less importance, except, perhaps, for some particular localities. Being a subscriber, I have the pamphlet which describes the composition of the compost. The receipt is so complicated as to be almost ridiculous, although it has been much simplified in a second edition, and it will, no doubt, be much more so in time.—*V. Paris, April* 6, 1838.

Jauffret's manure in England.—A gentleman of property, and a great mechanical inventor and promoter of agricultural improvement, has been at the expense of taking out a patent for Jauffret's manure in England. The specification is in the *Repertory of Arts*, No. 51, for March, 1838; and it is taken out in the name of A. B. F. Rosser, of New Boswell Court, London. M. Lozivy informs us that the specification is a correct translation of that of the French patent, of which we have no doubt, having compared it with the pamphlet alluded to by our correspondent.

The object of the inventor is stated to be, to reduce, not only "broom, heather, furze, rushes, and other vegetables, not hitherto used for making manure, as being deemed too difficult of decomposition, but also vegetables and weeds, such, for instance, as couch-grass, which it has hitherto been considered dangerous to introduce into manure, and the vegetating powers of which are by the invention totally destroyed. The principal object effected by the invention is the production of a rapid fermentation, the degree of which may be regulated nearly at pleasure; whereby the substances to be converted into manure are speedily and uniformly decomposed." The inventor next describes a liquid, which is to be prepared beforehand, of water, unslacked lime, a little sal-ammoniac, and kitchen-water, or any sweepings, dead animals, spoiled provisions, and filth form the dwelling-house. This water is to be allowed to ferment in a tank or pit. This is the first process. The next is to procure fæcal substances and urine; particularly human ordure, chimney soot, powdered gypsum, unslacked lime, wood-ashes, sea-salt, and what the inventor calls leaven of manure, being the last drainings from a dunghill already formed by the inventor's method. These articles being procured, and mixed together in certain proportions, (which we do not give, because we do not suppose there is one of our readers who would adopt them,) a quantity of the prepared liquid is to be poured over them, and the whole allowed to ferment for some weeks in a pit or cask. A piece of ground is now to be prepared by levelling and beating, so as to render it impervious to water; and on this raised floor the heap of straw, heath, or other rubbish which is to under go fermentation. is to be placed. The materials may be placed in layers, and thoroughly moistened and slimed with the liquid and its sediment. The heap may be raised to the height of seven feet, and then thoroughly moistened and covered over with the muddy sediment of the liquid. While the heap is making, it should be beaten or trodden down, so as to make the substances of which it is composed lie close and compact; and, when it is finished, it should be beaten all round with the same view. The heap is now to be covered all over with straw, branches, or herbage, so as to retain the heat and exclude the rain, or the drought. At the end of forty-eight hours from the completion of the heap, a fermentation of from 15° to 20° of heat by Réaumur's scale (66° to 77° Fahr.) has been found to have taken place; and the following day it has generally attained from 30° to 40° of Réaumur (99° to 122° Fahr.) On the third day, the top of the heap is to be opened to six inches deep with a fork, and the sediment thrown on the top is to be turned over, and another good drenching with the liquid is to be applied to the heap, which is again to be immediately covered up. About the seventh day, holes about six inches distance from each other are to be made with a fork, to the depth of three feet, and another drenching is to be applied, the heap being afterwards covered up again. About the ninth day, another drenching is to be applied, through new and somewhat deeper holes, and the heap is to be again covered up. After the lapse of from twelve to fifteen days from the making of the heap, the manure will be fit to spread. The fermentation is stopped by an excessive drenching, or by opening out the heap. If the materials of the heap are straw only, the fermentation may be stopped at 55° of heat; (156° Fahr.) otherwise it may be allowed to proceed to 75° Réaumur, (200° Fahr.)—*Repertory of Arts, March*, 1838, p. 172.

In order to give this process a fair chance of being introduced into England, M. Lozivy, one of the agents for the patentees in France, was invited to London, in order to prepare a heap of materials in the Jauffret manner. as an exemplification of Rosser's patent. He came in March, 1838, and prepared a heap of the new manure on the Earl of Spencer's estate, at Durnsford Lodge, near Wandsworth, in Surry, the residence of Mr. Patterson, the agent to Lord Spencer. When the heap was duly fermented, and fit to spread, M. Lozivy invited a number of persons to inspect it, on April 16, among whom we were included. It was formed on the south-east side of a field barn, on a raised platform of clay; ten feet or twelve feet in diameter, and covered with a very thick coating of straw. The outer covering of straw was removed, and the heap turned over, in the presence of the company; when the materials, which had been chiefly straw, were found to be thoroughly rotted, black, and moist; and, taken altogether, in a very fit state for using as manure. On examining them closely, many small branches of heath and furze were found, the leaves and the herbaceous parts of which were decomposed, and the bark of the woody part partially so. On the whole, it appeared to us that every thing that was proposed to be done was accomplished. It had required a much longer time than usual; because, owing to the extreme coldness of the weather, the heap could not for several weeks, be brought to a sufficient temperature to induce fermentation.

The impression on our mind was, that nothing more was done by this process than what may be done in any farm-yard with similar materials, moistened with the drainings of the yard, and similarly heaped up and covered. All the numerous ingredients in Jauffret's composition would, we believe, have no more effect than clear water, without the assistance of animal matter; and, therefore, if we were going to ferment straw, or other vegetable matters, without the aid of a farmyard, we should collect the dung and urine of all sorts of animals, and, simply throwing them into a tank or cask of water, allow them to ferment there; and, as soon as the fermentation took place, we would water the heap of materials, and cover it up. Of course, it would be of no use to attempt this except in mild weather; for even urine will not ferment in winter. We consider the lime, the gypsum, the sal-ammoniac, the soot, the wood-ashes, the sea-salt, and the refined saltpetre, as likely to have no effect whatever, in aiding the fermentation, though they would add to the value of the heap as manure.

All the good, therefore, which we consider may be drawn from a knowledge of Jauffret's process in England, by gardeners or farmers, is the confirmation of what they already know, though sometimes, perhaps, neglect to put in practice; viz.: that the fermentation of litter may be greatly promoted by watering it with the liquid which drains away from it, and by covering it closely with thatch, straw, mats, turfs, fagots, branches, or some other material, which will exclude rain and drought. Farther, that the urine of horses, and the urine and fæcal matters of the human species, promote fermentation in vegetable matters much more powerfully than those of cows, sheep, swine, or poultry; and, consequently, that the mixing together of the manures made by different animals will generally be found to increase fermentation.

Finally, if, in any part of Great Britain, there should be a quantity of such materials as, in France, would be made into manure by Jauffret's process, the shortest and most economical way would be to mix them with horse-dung, as practised in forming meadow-bank middens. In this way, one load of horse-dung might be made to ferment hundreds of loads of other fermentable matter.

Remarks.

We are enabled to give above, the earliest account of the process by which Jauffret's new preparation of manure is made. Since our first account of this discovery (p. 65, vol. vi. Far. Reg.) it has been cried up, by some, as a most wonderful and valuable improvement, and the discoverer denounced, by others, as a charlatan and a cheat. Now we differ from both these opinions; and we have not now, when the secret is fully revealed, to recall or retract any thing of our views stated in anticipation. (See page 125 of this volume.) Jauffret's process consists in applying highly putrescent liquids, as a leaven, to masses of vegetable matter, so as to produce speedy fermentation, and to bring the hard and insoluble materials to a state fit to feed plants. There is no new principle discovered or established by the explanation of the process; no value found that was not before known to exist. The dead vegetable matter, which natural causes, in time, would have brought to the same state, is merely converted to food fit for sustaining living vegetables in a shorter time. It is altogether a question of economy, as to the comparison of the cost of labor in the one case compared to the loss of time in the other—and of the waste of materials in both. Where it is important to reduce hard and coarse vegetable matters in very short time to *rotten* manure, this process will be effectual, and perhaps profitable. But where labor is worth more than the loss by delay, as generally in this country, it will be cheaper to let time, and the natural causes of fermentation, operate to produce the same results. Thus, we doubt not but that, by Jauffret's process, a farmer here might convert all the leaves of his wood-land to a manure fit for immediate action, and as rich too as the quality of the materials will furnish, and the rapid fermentation will suffer to be saved. But, if the same leaves had been scattered a year earlier, as top-dressing, on land properly constituted to receive and retain putrescent manure, and under a crop of young clover or other grass, perhaps a larger proportion of the fertilizing products of decomposition would have been put to use, and certainly with much less labor than is necessary for Jauffret's process.

On the other hand, we see no ground to denounce the process as a cheat. That it falls very far short of the value expected by credulous and sanguine advocates, and in that sense is, what we before guessed it would prove, one of the many agricultural "humbugs," is very certain. But no man of common sense and judgment could have believed that the manure could possibly contain more of prepared aliment for plants, than the materials used did of unprepared alimentary matter; and no one, acquainted with the phenomena of fermentation, would have believed but that the original quantity of alimentary matter must be considerably lessened by the fermentative process. Therefore, if Jauffret's manure is sufficiently prepared for immediate use, and contains all the strength of the materials used, *minus* the usual loss caused by rapid fermentation, it would seem that it is all that it promised to be, to judicious and reflecting minds.—Ed. Far. Reg.

GREAT SALE OF DURHAM CATTLE.

To the Editor of the Spirit of the Times.

Cincinnati (Ohio), June 29, 1838.

Sir—Believing that every thing connected with the improvement and sale of blood cattle must be interesting to the majority of your readers, allow me to furnish you with a transcript of the prices obtained at the sale of Maj. Chas. S. Clarkson's stock of Durham cattle, held on the 27th and 28th inst. at his (Clifton) farm, three miles from Cincinnati.

This sale was well attended by agriculturists and stock-breeders from the Miami and Scioto valleys of the Ohio, as well as from Kentucky, Indiana, Illinois, &c., and went off with much competition and spirit. The stock, as will be seen, was very superior, and showed fine keeping, and the prices which were obtained have fully justified the enterprising proprietor that in his attempt to introduce this valuable breed of cattle into the western country he has not labored in vain.

The gross sales amounted to $26,867 50, and a number of the animals have been since resold at a handsome advance of prices. I have herewith sent you a catalogue, of which you may make what use you please; and as this is the second or third sale (only) of similar stock ever held in this section of country, we ask you to furnish us with answers to the following queries, viz.:—

1st. Where (in the U. S.) has a larger number of fine stock ever been offered (at any one sale) at auction?

2d. Where have higher prices been obtained?

Waiting your reply, I am, sir, yours, &c.

Buckeye.

Note.—Imported *Minna*, and calf *Colossus*, sold for $1700, were repurchased by Maj. C. S. Clarkson at an advance; also *Lilly-of-the-Valley*, Maj. C. having made no reservation of bids at sale.

Seven young heifers not included in the catalogue brought from $75 to $150 each. J. J. W.

No. 1.	Minna the 2d, 6 years	$975
2.	Octavia, 4 years	725
3.	Pennsylvania, 7 years	725
4.	Lady Roan, 8 years	775
5.	Snow Drop, 4 years	800
6.	Florida and calf, 2 years	1075
7.	Belina, 2 years	875
8.	Kitty Clover, 7 years	700
9.	Prudence, 7 years	570

89.	Adonis, calved 23d April last, sold with No. 52.	
90.	Duke Aranza, 1 year	120

From the Western Carolinian.

COTTON MANUFACTORIES IN N. CAROLINA.

Since we became proprietors of the Carolinian, we have taken some pains to obtain all the information within our reach, concerning the cotton manufactories in North Carolina, knowing that it it would prove interesting to our readers. Our list is not yet complete, but even as far as it goes, many of our own citizens will be surprised to see the progress North Carolina has made in the establishment of manufactories:—it should be recollected that all these establishments, with the exception of two or three, have sprung up within the past three or four years. The following is, as far as we can ascertain,

A List of the Cotton Factories in actual operation in North Carolina.

1. Factory at the Falls of Tar river, in Edgecomb county. This is the oldest in the state; owned by a company.
2. Factory near Lincolnton, Lincoln county, built by a company,—but is now owned by Mr. John Hoke.
3. One at Fayetteville, owned by Mr. Mallet.
4. Another at Fayetteville, owned by Mr. Blackwell, and others.
5. One in Greensborough—steam power, owned by Mr. Humphreys.
6. One at Milton, owned by an incorporated company.
7. One at Mocksville, Davie county, owned by Mr. Thomas McNeely.
8. One or perhaps two, in Orange county owned by companies.
9. One at Salem, steam power, recently started, owned by a company.
10. One in Randolph county, owned by a company.
11. One at Lexington, Davidson county—steam power, if not already started, will be, within a few days, owned by a company.

Besides these, there are others now in the progress of building, and will soon be in operation.

List of Factories now being built.

1. One at Rockfish, near Fayetteville, a fine water power, owned by a company.

2. One near Rockingham, in Richmond county, water power—owned by a company.

3. One on Deep river, near Ashborough, owned by a company.

4. One near Leaksville, on Dan river, building of stone, owned by John M. Morehead, esq.

5. One in Surry county, on Hunting creek, owned by Mr. Douthet.

6. One on the Yadkin a few miles below Stokes' ferry, in Montgomery county, owned by Mr. Edward Burrage, and Co.

7. One on the South Yadkin river, 10 miles N. W. of Salisbury; owned by Messrs. Fisher and Lemly.

We understand that several wealthy individuals have purchased the buckhorn shoals below Haywood, in Chatham county, with a view of erecting a cotton factory—but have not learned whether they have not yet commenced operations.

It is also understood that an English gentleman has purchased Fullenwider's iron works—intending not only to enlarge the iron establishment, but to erect a woollen manufactory.

We also learn that there is a large cotton manufactory either in actual operation, or will be soon in North Hampton county.

Besides these, it is very probable that there may be one or two others in the state, either in actual operation, or in the progress of erecting.

From these facts it will be seen that North Carolina is making rapid progress in cotton manufacturing; and we think the work has just commenced. Her facilities are so great that the business once started, must go on. We have water power abundant, and cheap. We have the raw material at hand, and, what is remarkable, labor in the western counties of North Carolina, is cheaper than in New England.

The effects of the establishments already in operation begin to be felt throughout the state: three years ago immense quantities of cotton yarns were brought into the state by our merchants from the north, and sold to our citizens: now, not a hank is brought; our own establishments not only supply our wants for home consumption, but are beginning to export the article. Parcels of North Carolina yarns have already been sent to market in the city of New York, and find a ready sale at fair profits. Even now, several of our establishments are making preparations to commence the weaving of coarse cottons. We may venture the opinion that in two years, North Carolina will not only supply the demand for her own consumption with the coarser cotton fabrics, but also send them out for sale into the markets of the world. On the whole, the manufacturers of the northern states need not much longer count North Carolina as one of their markets; they may rather regard her as a competitor, and one, who, from the great advantages she possesses, will soon become very formidable.

THE MILK SICKNESS.

A disease, called *milk sickness*, has been exceedingly fatal in Kentucky, Indiana, and Ohio, for some time past. It seems to be equal in malignancy to the cholera, and has cut off hundreds of the inhabitants. The governor of Kentucky has offered a reward of one thousand dollars for the discovery of the origin of the disease, that it may be prevented.—*Boston Journal.*

From the Quarterly Journal of Agriculture, (for June.)

A DOMESTIC RABBIT-WARREN.

It will perhaps be superfluous to detail the most accredited methods of keeping rabbits in hutches, for the perusal of those persons, to whom the plan of a domestic warren may prove intelligible, because the hutch system is well understood, and is generally practised; we shall therefore merely offer a few hints and directions, impress two or three facts—the result of experience—and then proceed to the subject which forms the title to this paper. Air, dryness, good feed, cleanliness, with very little succulent food, are essential to rabbits, which are debarred, by this unnatural system, from the healthful enjoyments of exercise in their own native wildness. For our own parts, we confess, that we should almost as readily attempt to immure a tricky squirrel in a tread-mill cage, or confine the soaring lark within the wires of a prison, as we should retain in those close boxes the happy denizens of a warren: but as the animals are subservient to man—as these creatures among others, "are made to be taken and confined," it remains for us merely to advocate their helpless state, and to inculcate mercy.

It must be gratifying to all persons who are proprietors of live-stock, to conduce to their comfort and well-doing, for the mere delight of indulging in benevolent feelings; but, when it is made manifest, that, by obeying the dictates of nature as much as possible, and making their artificial mode of living approximate as nearly to that which was intended for them, as the relative states of freedom and subordination will allow, we shall be gainers in a double sense—we should evince unwonted stolidity, not to bend our attention to effect so desirable a result. It is very little known, that an artificial or domestic rabbit-warren can be constructed with ease, and at a trifling expense, which will not only allow a free range to the animals where they breed, and to enjoy themselves unmolested by man, but that they may be caught, examined, fed, and attended to, without the delay of five minutes. We have had ample experience of the feasibility and highly advantageous nature of this method of keeping rabbits, and therefore speak positively respecting its vast superiority over that stiving unhealthy system of hutching, at present considered the only alternative, with that of total wildness in the warren.

During a residence of nearly three years in that south-eastern portion of our island, the Isle of Thanet in Kent, we had practical proof of all we have asserted, and, therefore, feel no hesitation in prognosticating similar successful results to others who may be inclined to put the scheme in practice. We should premise, that those districts in which the subsoil is of chalk or other material, equally difficult of perforation, will be found most available for a domestic warren; a sandy soil, or one of rich soft loam, would afford too ready facilities for burrowing, and the animals would shortly find an exit and escape; therefore we would advise that only in chalky, stony, dry, impervious subsoils, the trial should be made.

In any part of the premises deemed most convenient, a court or a stable-yard for instance, the soil must be removed full six feet deep, and three wide; a foot from this opening another must be made of the same depth, but *four* feet wide; the latter hole is to be bricked all around as well as the floor; and at the bottom of that part which divides it from the other space, an opening must be made, large enough to admit a full-sized rabbit to pass through, thus forming a communication between the two compartments. Down the party-wall an iron plate or door is to be slided at pleasure, in two grooves, by a rope from above. Light covers of wood, or of oil-cloth, or tarred sail-cloth, are to be fitted with hinges, on a frame-work of stout wood, and made to open towards the south, in order to admit all the warmth possible from the sun. Every morning these covers should be propped up with sticks, in which deep notches must be cut, so that the opening may be wide, or narrow, according to the state of the weather, as it is not advisable to allow more moisture to find access to the rabbits that can be avoided. Indeed, we omitted to say, that, while the excavations are being made, a drain ought to be constructed in each, over which a small iron-grating should be fixed, and the floors ought to slope towards these exits; thus dryness, so essential to the health and comfort of the animals, will be insured.

The larger of these two excavations, which we have been describing (the bricked compartment,) is the trap—the smaller we will call the warren. In the trap, *and only in the trap*, the rabbits must be fed. It is self-evident, that the more nearly to a state of nature we approximate the condition of our live-stock, the greater range we may afford them in their diet. Green food must be very sparingly administered to all that are confined in hutches, but those which are allowed a roomy space, with the salutary exercise of burrowing, may with safety be indulged with green food at their own discretion—attention being paid to select those esculents which they are known to prefer when in a wild state. We incline to think that animals in a state of nature are liable to no disorders, but that we, in consequence of our ignorance of those wise laws by which they are taught instinctively to vary their diet, and thus preserve their health, inflict diseases upon the unoffending creatures, which we then exercise our folly, not our rationality, to remedy: oh, the torture to which ignorant and conceited man subjects his speechless dependents! Rabbits in hutches thrive *in spite of* cabbage-leaves, not *by means of* that rank succulent unnatural food. Fifty generations of these animals have lived and passed away, in their wild extensive warrens, without the possibility having occurred of their encountering a cabbage-leaf. The mild beautiful herbage, that evident staple of their lives, as bread is of our own, varied with the thousand flavors, and healthful adjuncts which they meet with in the surrounding weeds—as we judiciously assist digestion with different condiments—this natural food, grass, is never given to rabbits in hutches, although they can obtain little else in the vicinity of their native warrens.

We would then strenuously advise that not any of the rank succulent vegetables of the garden be offered to creatures so artificially placed, that the option of choice is no longer in their power. Twice, or even three times a-day, there should be a supply of bran and oats in troughs, let down into the trap by means of a stick fastened to each trough, about four feet in length. A few handfuls of fresh grass, with its attendant weeds, ought also to be given daily, and the refuse should be taken away every two or three days; this can be managed with ease and expedition by means of a small ladder. It will be obvious that the trap is made deep and wide, in order to admit of easy access for the facility of cleaning the place and selecting the rabbits, which is effected in the following manner. As soon as the food is let down, the creatures, from habit, will run through the trap-door into the trap, and when it is judged that they are all collected, the person (keeping out of sight, for they are naturally shy, and would run back into their warren if they were to see any one, or hear a noise) must let down the trap by means of the long rope, and he can then select at his pleasure.

We think it likely that some of our readers may be inclined to question the utility of the opening to the warren, and may suppose that the trap would be sufficient; we assure them it is essential, for not only must a space be cleared for them to begin their operation of burrowing at that depth below the surface, but occasionally it may be requisite to clear away any loose soil which they may have excavated, as well as to secure the manure, which is valuable; besides, the two openings afford a free circulation of air, and more light than could be admitted by the trap only.

In many districts of this country not a warren or a wild rabbit is to be seen for twenty, nay, fifty square miles, yet, at all the poulterers' in large towns within those districts, *wild* rabbits *so called* are always to be obtained. There exists an imaginary preference in favor of wild rabbits, and therefore the public is never let into the secret, that they never *purchase a wild one*, excepting within an available distance from a warren. *All others* are bred in hutches, and all warranted *wild!* This we know to be fact. Independently of the superior health enjoyed by creatures nearly in a state of nature, other contingencies are prevented by the domestic warren system. Rabbits are exceedingly shy, and those unnatural propensities, the destruction of their young by the fathers, and devouring them by the mothers, which many writers have endeavored to account for, *quite unsatisfactorily*, are avoided; they are, too, probably caused by the officiousness and ignorance of man; in the first place, by interfering with the mother, in the next by having debarred her from that species of diet which her own instinct would have led her to select, to suit her maternal duties.

As our present notice refers only to the subject of a domestic warren, we abstain from offering any remarks or advice on the numbers to be kept, the sorts and advantages of this prolific and valuable live-stock, because there are few small farmers who are not aware of all we could say, by experience, in the troublesome, and every way ineligible system, of hutches, when compared with that of the domestic warren. We repeat, that we have had ample experience of its perfect success, and had it no other merit than being a mercifal and rational plan, it ought to supersede all others.

From the Quarterly Journal of Agriculture, (for June.)

LUCERNE AND SAINTFOIN.

By Mr. Towers.

Lucerne is the plant of plants! yet its merits, though undeniable, are but imperfectly understood. It is a native of England, belongs to the seventeenth class, fourth order of Linnæus, *(Diadelphia decandria)* and to the natural order of *Leguminosæ.* It is a member of the genus or family *Medicago,* medick, distinguished by having ten stamens, one of them distinct from the other nine. One seed-vessel, a *legume* or pod, spirally twisted or sickle-shaped. The figure of the blossom is that termed butterfly-shaped, *(papilionaceous.)* One plant *(M. sativa)* grows to the height of two feet or more; the stems are upright and firm, the foliage ternate, of a rich lively green, the leaflets saw-cut at their edges, the flowers are produced during June or July, in spikes, and are of a full violet blue. I extract the following from Loudon's Encyclopædia of Gardening, partly to prove the great antiquity of the culture, but particularly to show the fallacy of the concluding observations, and thereby evince the worth of the plant.

"It is highly extolled by Roman writers; it is also of unknown antiquity in old Spain, Italy, and the south of France; is much grown in Persia and Peru, and mown in both countries all the year round. It is mentioned by Hartlib, Blythe, and other early writers, and was tried by Lisle, but it excited little attention till after the publication of Harte's Essays in 1757."

"But though it has been so much extolled, it has yet found no great reception in this country. If any good reason can be given for this, it is that lucerne is a less hardy plant than red clover, requires three or four years before it comes to its full growth, and is for these and other reasons ill-adapted to enter into general rotation."

I have grown lucerne during four or five years, and previously I had witnessed its great success and extensive culture in the Isle of Thanet, Kent; there it is a *sine qua non,* because it affects chalky districts, and sends down its wiry elongated roots deep into the interstices of the chalk. It succeeds perfectly in sound loams, and therein appears to me to require little manure. *Hardy it is*—and as to tardiness, though the plant may acquire strength, and improve during four years, the fact is beyond controversy, that if sown in drills about the third week of March, and the spaces between the rows (from nine to twelve inches) kept clean by the hoe for the first three or four months, the young plants, if favored by a mild spring and genial showers, will advance with so much vigor and rapidity, that a first cutting over with the scythe can be made in June or July, and three other cuttings will follow in pretty regular succession, between the latter period and the first of November.

Seasons will of course vary; soils and other auxiliaries may be more or less favorable; but that which I have stated has occurred; it is the result of my own experience and practice. I have during five seasons witnessed the abundance of green food, which is produced by a plot of young plants, the supply being ample for a cow, even within four months after the sowing of the seed. I am thus authorized to refute, upon the evidence of facts, the charges contained in the concluding paragraph of the quotation. In cutting for a cow it will always be advisable to take the plant when it is tender and juicy, and such it will be when about a foot high. I have thus cut my plot over six times after the first year, but they who leave the plants to grow two feet high will find the stems rigid, fibrous, and less juicy; and that what they gain in bulk will be lost in time and quality.

As to the trouble in managing an established crop, it is really nothing. Though I allow it is good to hoe twice during the summer, as the plot is mown, piece by piece, yet *one general fork-digging* at that period of early spring, when the plants exhibit the first symptom of growth, so as to remove every weed and loosen the surface of the soil, will be amply sufficient to secure the safety and full development of the herb. Upon the whole, lucerne is a plant of the utmost value; for if the seed be good, the ground rich and in heart, and rendered deep in the first instance by a thorough trenching, the young plants start into lively growth, attain strength in the shortest possible time, and yield a bulk of luxuriant herbage that cannot be surpassed. If the plant require four years to attain its maximum of power, it is still a giant even from its infancy, advancing from strength to strength.

Well might the writer of a recent agricultural report (of Norfolk if I mistake not) recently exclaim, "What a plant is lucerne!" I re-echo this introductory "note of admiration," and will unhesitatingly assert, that if abundance, permanent and unfailing, particularly in shallow soils upon chalk-rock, be the object of the farmer, he will attain it by the cultivation of lucerne. The rotation must be improved by it, as in point of produce it will yield double the bulk of grass from an old sedgy meadow.

The soil which is most favorable to the perfect growth of lucerne is worthy of consideration. Chalk is what it affects, and therefore we find it most generally cultivated in Kent, and those parts of the southern coast wherein the subsoil is a chalk-rock. But my fine plot grows in a rich, deep, and rather sandy loam; the subsoil is indeed chalky or marly, but at a considerable depth. It was prepared by taking off the turf, trenching to the extent of three spits, and placing the turfs, their grassy surface downward, at the bottom of each trench. Upon these reversed turfs a sprinkling of common salt was given, and the earth was returned into the trench, with the precaution to keep the heavier and inferior soil below the fine black earth of the surface. Due preparation affords a rich and permanent pasture for the wandering roots; and my piece, of hardly one-third of an acre, has been so undeviatingly productive, with little subsequent manuring, that, in a showery season, we have found in cutting over the end where we began ready for the scythe again before the mowing was completed. Lucerne is known to produce much milk, perhaps more than any other of the artificial grasses *(Leguminosæ)*; but some complain that it communicates an austere or bitter flavor. I doubt the fact; but would always recommend that it be not given quite fresh to a cow, particularly at an early period after calving. If the required quantity be cut over night, it will be fit for the stall by ten o'clock of the following morning; and again, the afternoon meal should lie exposed to the sun for two or three hours before it is used.

A well prepared field, if kept clean by the forking, will remain productive for more than ten years; but as a change of crop always promotes abundance, it would be advisable to prepare a successional plot every six years.

The grass and weeds raised by the fork, and raked up with the small quantity of earth. adhering to the roots, if salted and sprinkled with quicklime and placed in a heap, will form a most excellent manure for the lucerne. The cuttings *here* are usually over by the end of October; the herb then becomes, as it were, torpid, and whatever manure is applied should be given as a top-dressing during the winter's state of repose. The surface must not be disturbed at that season, nor till the herb begins to grow, then, as I have before said, the fork-digging will effect all that is absolutely indispensable; it will turn in the remaining manure, remove the encroaching weeds, and open the soil, burying a fresh surface into contact with the advancing rootlets. The experience of one or two seasons, under commonly favorable auspices, will verify all that I have asserted.

Somewhat resembling lucerne in character and habits is the French grass or saintfoin *(Hedysarum Onobrychis)*, a lovely flowering plant, rich in herbage, and also a native of Britain. The grand object of agriculture ought to be the renewal of soils, and the adaptation of crops; and as science advances, and its sons become more influential, these objects will be attained.*

SEEDLING TREES FROM THE SEED OF THE MORUS MULTICAULIS, OR CHINESE MULBERRY.

There has been much said in this journal, during the last four years, as to the *kind* of products from the seed of the Chinese mulberry. We were the first in the United States to announce that the seeds could not be relied on to produce plants like the parent stock; which being itself an accidental variety, would generally produce other varieties from its seed. This information was totally disregarded by the agricultural public; and one effect of this disregard was the permitting the success of extensive frauds which were perpetrated in sales of what was called Chinese mulberry seed—which seed, was in fact, *not* the product of the *morus multicaulis*, (and was so admitted, after the cheat had been discovered,) and which, if it had been, would most probably have been worth no more.

In one of our pieces on this subject, we promised an experimental proof, which will now be furnished. In the editorial remarks on page 711 of vol. iv, it was said that "though believing that the seeds of this plant are not to be relied on for reproducing their own kind, we are not inclined, in any case, to trust to reported opinions, or authority that is the least doubtful, when the facts can be tested by accurate experiment. We have the means of making such an experiment, in seeds of the *morus multicaulis* taken last summer from trees which grew within the enclosure of the high walls which surround the Penitentiary of Virginia; and near which no other kind of mulberry grew, to affect the seeds by a mixture of the fecundating farina. If *these seeds* will not produce the *morus multicaulis*, it may be thereafter safely pronounced, that seeds are not only not to be relied on to produce this kind, but that the result of reproduction of the like kind rarely, if ever, occurs."

The seed were procured, at our request, by Dr. Lewis W. Chamberlayne, of Richmond, who, as attending physician, visits the institution every day, and by whose direction the seed were saved by one of the attendants, and delivered to him as soon as they were gathered and separated from the pulp; and were placed in our hands very soon after. The trees are in the yard, surrounded and overtopped by the very high walls that enclose the buildings, and no other kind of mulberry is near. For these reasons, there was as much security as any situation and circumstances could possibly offer against the access of fecundating farina of other trees to the flowers of these trees; and there was equal security against any change or mixture of the seed, after they were gathered, by mistake, or even by design, if there could be supposed any possible object in the gatherer to produce such deception. We placed the seed in the hands of our friend and near neighbor, S. D. Morton, esq., whose taste and fondness for the higher departments of horticulture furnished security for his strict attention to so interesting an experiment. Some of the seeds he planted in the open ground of his garden; and of these very few germinated, and only after a long time. The balance were planted in his hot-bed, sprouted soon, and grew well, and were transplanted afterwards to open ground. Though, to our mind, the result was satisfactory in the first summer's growth, we have waited for the second, and for the larger size and full development of the leaves, to make report. For this purpose, the plants have been again carefully examined, on the 23d July.

There are now standing twenty-six trees—the largest about five feet high. The few which had been planted in the open ground, and not transplanted, have suffered by their close and shaded positions, and are not more than eighteen inches in height. There is much variety in the appearance of the plants, in the shape and sizes of the leaves, &c. But there is not one which is not entirely and manifestly different from the *morus multicaulis*, of which there is a row parallel to, and within a few feet of the transplanted seedlings. None of the leaves of the latter are so large, nor so smooth, nor have they the convex form which is so marked in the *morus multicaulis*. In general appearance, the young trees are more like the common native mulberry, *(morus rubra,)* than the white—and far more so than the Chinese.

---

* The climate of Scotland is far from being genial to the growth of either lucerne or saintfoin.—EDITOR.

So far as negative proof is to be depended on, this experiment may be considered decisive. But though it is now proved, as we have before maintained, that no reliance should be placed in continuing the kind by seeds, still we would not deny (even in the absence of facts,) that the seed of the variety may *sometimes* produce its like kind. Gideon B. Smith, esq., of Baltimore, has raised the true multicaulis from seeds; and therefore there is no doubt of the fact, as it could not rest on better authority. But such results are so rare, and the failures would be so many, that the fact, however curious and interesting, is of no value for practical example, even if the seed could be obtained in quantity, and at a cheap rate.—Ed. Far. Reg.

From Loudon's Gardener's Magazine (for June.)

JOYCE'S NEW MODE OF HEATING.

When we noticed Mr. Joyce's stove in our January No., p. 57,* the nature of the fuel was an entire secret. It since turns out to be nothing more than charcoal prepared in a manner, which, though it deprives it of its smell, and, perhaps, diminishes, in some degree, its deleterious properties, yet leaves it of the same nature as it was before, though not so perceptibly dangerous, from its want of any noxious effluvium. Mr. Joyce's stove, therefore, has entirely failed in realising all the high expectations that were formed of it, and cannot be recommended, either for plant-houses or human habitations. The manner in which the charcoal is deprived of its smell, is said by some to be by boiling it in any alkali, such as lime-water; and this may afford a useful hint to gardeners, where they are under the necessity of using a charcoal stove in fruit-rooms or plant-houses, on extraordinary occasions.

ON "RINDING" OR RINGING FRUIT TREES, TO FORWARD THE PRODUCTION OF FRUIT.

To the Editor of the Farmers' Register.

Richmond, July 6, 1838.

About ten year since, I met with an old magazine, containing experiments on fruit trees, among them, one on "rinding." The process is simply to make an incision near the trunk of the tree, with a sharp knife, all round in two places, at about one-eighth of an inch apart, and the rind or bark peeled out down to the wood. Care should be taken not to wound the wood. This should be done just as the buds are ready to burst. The philosophy of the process is, the sap already in the branch, being checked in its return, when most of it would be consumed in forming the tree, produces fruit in its stead.

The exudation from the wound ceases very soon, and the incision only leaves a ring, which will be easily forgotten while beholding the luscious fruit occasioned by it. I communicated these facts to a friend who resides near this city, and who will take pleasure in showing the results of his experiments, detailed below.

In the spring of 1837, he "rinded" a limb of a young apple-tree, about 7 feet high. It bore twelve apples on the whole tree, on the limb rinded seven apples, on the rest of the tree five only. Two of those on the limb operated upon being equal to three of the others in weight.

The next experiment was upon a blue plum-tree, which had not borne more than a few dozens for some years. One branch only was operated on, and the limb was full of the finest fruit, while the balance of the tree, as usual, produced a very small quantity of inferior plums. This spring, 1838, he operated upon an early young pear-tree. The whole tree bloomed before the branch that was cut did, and was killed by the frost; after which the limb put out and bore a bountiful crop of fruit.

The latter, I would remark, might be the result of the peculiar season; and may not be considered a fair test; but the former, I think, establishes the fact, that unfruitful trees may be made productive.

J. W. S. Lownes.

EXTRACTS FROM PRIVATE CORRESPONDENCE.

Union District, S. C. March 25, 1838.

I have made use of some exertions to procure some new subscribers to your valuable journal; but regret to say that I have not been able to procure even one, in consequence of a foolish and inveterate prejudice against *book* farming. This prejudice is more general than I had thought, though it must yield before the light of knowledge, and I hope to be able still to add some new names to your list. My exertions shall be unabated. On the subject of hill-side drains, I want information; I have seen several communications in the Register for and against the system; but nothing in detail, or not sufficiently so, to enable me to satisfy myself as to the *quo modo*. I am satisfied of their efficacy, if accurately done; and if not accurately done, that they are manifestly injurious. If you could furnish such information, or elicit that information from some one of your correspondents conversant with the subject, you will much oblige your obedient servant, &c.

[If those southern and western planters, who scorn all book-farming, and are sure that no agricultural journal published in a remote region can yield to them profit or instruction, would listen to our reasoning, and not consider the gaining of their subscription money to be our *sole* object, we could name very many subjects on which they need such instruction, and might greatly profit by receiving it through the channel of such an agricultural journal. We will name but the one to which our correspondent refers—the graduated ditches, or beds, on hill-sides, to guard the soil against being washed away by heavy rains. Full information on this subject was given in several communications to the first volume of this work; (which our correspondent had not then seen) and we hesitate not to declare, that if the instruction there offerred on that subject alone, had been known to the planters of the hilly lands of South Carolina, Georgia, and Alabama, and duly acted upon for the last twen-

* Copied in the Farmers' Register, p. 62, vol. vi.

ty years, the value of soil, of crops, and of labor, thereby saved to the cultivators, would have been worth millions of dollars.

A very intelligent farmer of this state, who had learned and profited by this practice, settled a cotton plantation in the hilly region of Alabama. Though on new and, as yet, rich soil, he resolved to prevent its waste and destruction; and to that end, forthwith, commenced a general system of hill-side ditches. Their useful operation was soon manifest to every observer; and an older settler, (who probably despised book-farming as heartily as our correspondent's neighbors,) pronounced the practice to be the greatest improvement ever introduced, and that the introducer was a public benefactor, whose services to that country would prove to be beyond estimation. We fully concur in this opinion, But if the new settler had obtained his knowledge of this improvement from the Farmers' Register, as he might have done, and as every hill cultivator in the south and west might now easily do, would it not have been "*book-farming*"? Even if the still farther fertilizing of rich virgin soil is not required, the preservation of existing fertility surely is desirable; and especially if it is cheaper to preserve than to waste the richness of the land. And even if neither of these important objects is cared for, still it is as important to the cultivators of the lands of the most exuberant fertility, no less than to others less happily situated, to be apprised of agricultural news, and of the advances of agricultural knowledge—and thereby be enabled to learn every new value of agricultural labor and products—and every means of making labor cheaper and more effective, by better implements and stock, and better management.]

Montgomery county, Ala., March 16th, 1838.

I am a planter of but little experience, and regret much that your work, with the aid of which one may profit so much from the experience of others, is not better calculated for my latitude. Hundreds of planters here, like myself, require to be taught much that might appear common-place to the experienced; and if your work contained the desired information, I am pursuaded its circulation would be greatly extended in the south-west. The difficulty of procuring well written essays and valuable papers upon our peculiar soils, staple and mode of culture, I am aware, must be very great to a distant editor. But this is a difficulty which it would be much to your interest to overcome. Southern cotton-planters are generally educated, intelligent, reading men; and the Register would be very popular among them, if it taught them their true policy and interest, with half the skill and accuracy, which it has hitherto displayed in relation to the farming interest of the "Old Dominion." Virginia must be well-nigh ready to graduate under your instruction; turn then to the "destitute south-west" and give us the benefit of a few lectures.

[We lament that our journal has not more southern communications. But we deny that we have been remiss in endeavoring to obtain them. The fault is in all those, like our correspondent, who *can* write and instruct, and will not do so. We have throughout paid especial attention to the agriculture of the more southern states; and never fail to publish every valuable article found in other prints, as we have published every original communication sent directly from the south to this work. And without counting any of the articles exclusively useful for the south, and though we have never been south of Raleigh, nor west of Virginia, we dare to assert that the observations on the prairie soils of the south and west, taken in connexion with the doctrines on the nature of soils in general, as presented in these volumes, offer as much of useful and profitable, and practical instruction to the people of the south and west, as might have contented them in a work printed among them, and designed exclusively for their patronage. Yet we must confess, with feelings of disappointment and mortification, that these available services seem not to have been there appreciated, and indeed are scarcely known. We have not withheld our "lectures" from the "destitute south-west," and are ready to deliver them as long as they are desired. But not for the reason that they are not still very much wanted, (though but little *in demand*, in mercantile language,) at home.]

Clarke county, Va. 22*d April*, 1838.

I received with my first No. of the Register, your "Essay on the causes of the formation of Prairies, &c.," which I read with much interest, and with entire acquiescence in the soundness of its views. I do not know whether you are aware of the fact, that this part of the valley—including a large portion of Jefferson and Clarke, and a less one of Berkeley counties, was, when first settled, and until about 80 years since, a perfect prairie. It is a highly calcareous region, and its geological character generally corresponds, I believe, with that of the "great west." It is now covered with a lofty growth of trees—though the forests are more open and sparse than in the argillaceous soils —and without any undergrowth except grapevines. I believe, however, that the trees here are short-lived—having always observed that a portion of them, in the midst of their apparently vigorous and rapid growth, die annually, without any extraneous or obvious cause. These facts corroborate your theory, that soils which contain a large portion of calcareous matter are unfavorable to the growth or perpetuity of trees; and that the luxuriant crops of grass which they produce, and the abundant supply of dead wood, where wood ever did exist, afforded sufficient food to the annual fires, which swept over these plains and destroyed their feeble efforts to throw up a woody growth; and hence the formation of prairies, wherever they exist.

Mobile, June 23.

I am pleased to see the zeal and ability with which your paper is conducted, and think it the best agricultural paper we have ever had, and likely to be of infinite advantage, though the progress will be slow. The taste has to be created with that class with whom it will be most useful.

The crops of corn in this state are remarkably fine, and may be said to be made. The cotton crop was worse ten days ago than I have ever seen it at the same time. Many places for 50 acres together there were not 50 stalks in the bald or open prairies, and the light sandy lands. The crop has been replanted, and the young cotton shows very prettily, and the weather has so far been very suitable for it; and with a cool fall the young cotton may make a ¾ crop, and the old cotton more. The month of May was very cold, the thermometer on the 24th was at 40° ; and as the cause was a general one, I think it a fair inference that the crops have every where been injured. There is no calculation to be relied on as to the probable crop for the year at this time of it; as it depends so much on the season from this time on.

Since writing the foregoing I have received a letter from Arkansas. The month of May was cold and rainy, and the crops were very unpromising.

Baltimore, April 16, 1838.

* * * Your article on "hobbies and humbugs," it seems to me, is rather severe, and calculated rather to depress the spirit of enterprise than encourage it. If we are to have no *new thing*, till it has been sufficiently tried to prove that it is not a hobby nor a humbug, we might as well give up improvement for the time. * * *

I differ with you on some of the "hobbies and humbugs," I perfectly agree with you on some others. The Baden corn, for example, is an old worthless *pony*, that has been turned out to die of old age three or four times within forty years past; (I don't wish you to suppose that I have been an observer of these things myself for forty years, as I am not old enough for that—) and it seems that even old age won't kill it, or if it does, that it won't stay killed.

Lynchburg, July 11*th*, 1838.

Our harvest is not yet completed. All accounts, until very recently, have concurred in representing the wheat crop as a very superior one. Hence, on a visit to the country ten days ago, I was much disappointed; I saw very little that was prime, and much that was inferior, and some not worth cutting. Early sowing in good ground, well prepared, looks well, a good deal of it, and some, very well, but on examination, the head, a third or a half, has three grains in a mesh, then two, with four or five at top with one, and some entire skips. And I am not certain that any of the *grain* is superior. Such is the best. There is still a large quantity of thin corn-ground seeded, unprofitable as it is. This is all inferior, and a good deal worthless. The crop is all late, but some is much later than the rest, as usual. Nearly all of this, including northern exposures, is sorry. I should say, that, in quantity, the crop is vastly short of the general estimate, and that a large portion is of inferior quality. It is proper, however, to say that my observations are confined to a limited region, from this place to the Blue Ridge the north side of Bedford, 20 odd miles.

Rye, of which the quantity sown is much diminished, is better than for several years. Oats, moderate; on thin land, not good as common. Corn backward, and more missing than usual, but a favorable season may yet make a good crop. Some tobacco land has been planted in corn, for want of plants, and from that circumstance and a scarcity of planting seasons, the prospect is unpromising.

Elizabeth City Co. Va., July 20.

Our wheat crop was generally good. More wheat has been made this year in our county than was ever grown before in any two. The crop of corn though backward, promises a fair yield.

Things have much improved here since your visit to Back river, (in 1836) and land is growing daily more valuable. We are cleaning up and manuring in every direction; and without designing to flatter you, I am free to confess that much of this improvement is owing to the influence of your valuable paper.

I was much pleased with your description of Gloucester, and felt more than ordinary interest in your remarks, because they applied with peculiar force to my own neighborhood. Your theory about wide beds is certainly true. I know from *experience* that 11 feet beds suffer from wet much less than 5 feet ones. At any rate I will try it this fall, and will let you know the result.

[From the letter of a brother editor.]

Pray how do your subscribers pay? Ours are horribly remiss.

[We may answer that our subscribers are
"Like Jeremiah's figs,
The good, are *very good, indeed*—
The bad, too bad for pigs."]

THE WHEAT CROP.

The wheat harvest has been finished, and without much loss from bad weather in general, though many crops on the lower James river suffered severely from a hurricane which tore down shocks, and scattered the sheaves, wherever its power reached. In that region the crops are found to be less productive in grain than in straw; and the yield will there be less, by perhaps one-fourth, than was counted on in our last report, made during harvest. Similar disappointment has been found elsewhere, as stated in a foregoing extract. Still the general crop will be a large one. From many other parts of the country, there is yet no abatement stated of the first anticipations of great product.

MONTHLY COMMERCIAL REPORT.

The weather has been very favorable for harvest, and the crops of wheat and oats were stacked in dry order. The showers of rain were occasionally violent, but of short duration, and during the last fortnight the weather has been dry, and the heat extreme. The product of wheat, so far as ascertained, falls short of expectation; but proves fair for the quantity sown, and the quality is good.

Some few farmers who undertook to get their wheat ready for delivery in this month and made contracts in June, obtained $1 50 per bushel; but this price soon began to decline, and subsequent contracts have been successively at $1 40, $1 30, $1 25, and $1 20, for delivery in August. Prices are expected to go still lower, unless a prospect of foreign demand shall check the decline. The crop throughout the United States, is supposed to be the largest that has been made for several years.

The inspections of tobacco to 1st inst. show double the quantity to the same time last year, but this arises chiefly from a similar difference in price. A considerable portion of the crop of 1836 has been brought to market since the 1st October, 1837, and is counted in the present year's inspection.

The range of prices is from $4 for inferior and partly decayed lugs, to $11, for choice leaf. The inspections in Virginia, it is supposed, will reach about 45,000 hhds. and those of Kentucky about the same, which, with the addition of Maryland, will furnish about an average of the usual quantity for export.

The growing crop is said to be unpromising, particularly as to the quantity.

The quantity of cotton reported in the table of receipts at different ports of the United States, reaches nearly to 1.800.000 bales, being an increase of about 450,000 bales on the receipt of last year, partly arising from the same cause that the inspections of tobacco exhibit so large an increase.

Considering all circumstances, prices have been well supported. They have advanced 1½ cent per pound in the last 6 or 8 weeks, partly owing to decline in freight, and rise in exchange on England. Sales have been small in Petersburg as high as 11½ per cent., the range of prices 9 to 11½, but some reaction is now felt, and the accounts from England to 16 ult. are not so favorable as those which preceded; indeed so large a quantity as 1,-800,000 bales had not been anticipated.

It is confidently expected that the banks in the Atlantic states will generally resume specie payments next month, and that the western banks north of Tennessee will follow the example.

Specie has fallen to 2 to 3 per cent., exchange on England 8½.

THE FARMERS' REGISTER.

VOL. VI. SEPTEMBER 1, 1838. No. 6.

EDMUND RUFFIN, EDITOR AND PROPRIETOR.

ON THE FREQUENT FAILURES OF THE WHEAT CROPS.

To the Editor of the Farmers' Register.

The successive failures of the three last crops of wheat, and the partial injury to the present, have caused a general inquiry, why this crop is more uncertain than in former seasons, and what remedy can be found for this misfortune, which threatens to destroy the cultivation of wheat, at least in Virginia. Being extremely partial to the golden grain, and thoroughly convinced that it ought to be the staple crop of the Old Dominion, I venture, as its friend, to give you some thoughts on the subject. Every candid observer must admit that the last four seasons have been very unfavorable—severe winters, and excessive rains in May and June. The present crop was very promising until the rains and exceedingly hot weather, which have created a good deal of rust in parts of the state, but still left a crop which will probably make us independent of foreign supplies.

Those causes have been beyond human control, and, so far as they are concerned, we can only submit to the decrees of an all-wise Providence; but it behoves us, as rational beings, to inquire whether there do not exist other causes, which may be removed by human effort.

There certainly is something very striking in the reflection, that a country always producing sufficient bread-stuff for its inhabitants since its first settlement, and latterly exporting more of that article than any other, should, with the view of affording a better home market to its agriculture, for the benefit of its manufactures—and in less than twenty years from the adoption of this policy—find its agriculture so oppressed, that these very manufacturers have to resort to foreigners for their daily bread. Thus showing the retributive justice of Heaven, who hath said: "thou shalt not muzzle the ox that treadeth out the corn." But, thanks to the wisdom or fickleness of our legislators, this state of things is rapidly changing; and it becomes us to inquire, now that the efficient or remote cause of the disease is about to be removed, how shall the patient be restored to his pristine health and vigor? Were this the case of a lovely form, whose freshness and beauty were fast fading away, without any evidence of fixed disease, the physician would say, "Restore her native air, and place her amongst the soft breezes of the valley, or the bracing air of those mountains, the scenes of her childish gambols, and we may hope to see the rosy-lipped cherub again bounding, like the antelope, from hill to hill."

Now, following this metaphor, may it not be well to inquire wherein has agriculture degenerated under its oppression, and to endeavor to restore that vigor, which was the cause and the consequence of its former health. Many of those who now guide the operations of the husbandman, have no personal recollection of the former state of things. But you and I, Mr. Editor, can now use the familiar phrase of some twenty years since. We were both reapers of the golden harvest, which seemed almost like coining money, immediately after the late war; and though schoolboys at the time, we recollect the high price so long kept up during Bonaparte's wars.
